ABSTRACT

By combining precision catalysis from biological enzymes with unique physical and chemical properties of nanomaterials, nano-bioenzymes is an emerging, robust, transformative field created from the intersection of enzymology and nanotechnology. The most sustainable, least toxic way to create nano-bioenzymes is via green synthesis methods that use phytochemical-containing plant extracts, secretions from microorganisms, and other biobased renewable resources to act both as reducing agents and capping agents for the phytochemical-assisted formation of nanoparticles. This review article summarizes and synthesizes peer-reviewed articles published during the period 2015-2026 on the principles, methodologies and applications of green synthesis of nano-bioenzymes mediated via plants. The article includes the mechanistic aspects of how phytochemicals assist the formation of nanoparticles; how to immobilize enzymes (i.e., laccase, peroxidase, lipase, cellulase, amylase, protease and superoxide dismutase mimics) on a range of nanoplatforms (i.e., silver [AgNPs], gold [AuNPs], zinc oxide [ZnONPs], copper oxide [CuONPs], iron [FeNPs], titanium dioxide [TiO2NPs] and manganese dioxide [MnO2NPs]) and how the resulting nano-bioenzyme systems can be utilized in various ways, such as biomedical therapy, biosensor development, environmental bioremediation, food processing, biodiesel production

and neuroprotection. Three summary tables summarizing key findings of green source-enzyme-nanoplatform combinations and their respective application results, and summary comparing green and conventional chemical synthesis methods will be presented. The review further highlights current challenges including stability under physiological conditions, batch reproducibility, and regulatory pathways, while charting a roadmap for future research toward industrial scale-up of green-synthesized nano-bioenzymes.

Keywords: Green synthesis; Nano-bioenzymes; Bioremediation; Biosensor; Nanoparticles; Sustainable nanotechnology

INTRODUCTION

Enzymes are regarded as among of nature's best catalysts since they can accelerate biochemical reactions with remarkable selectivity, operate in mild environments, and leave no leftovers that can be hazardous to the environment. Pharmaceuticals, food production, textile manufacture, and environmental remediation are just a few of the businesses that have tried to take use of the possibilities of using enzymes on a broad scale over the past few decades. However, soluble free enzymes have drawbacks that prevent their widespread application in these industries, such as their susceptibility to denaturation under extreme pH and heat conditions, their high separation costs, their incapacity to be reused, and their leaching from reaction vessels, which complicates product recovery [1]. The goal of the field of immobilization of enzymes was to eliminate all of the constraints related to free soluble enzymes; however, toxicity, non-biodegradability, and reduced enzyme loadings have been introduced by traditional support matrices for enzyme immobilization, such as synthetic polymers, silica beads, and activated charcoal [2]. The use of enzymes has undergone a major transformation with the development of nanotechnology. Because of their exceptional surface area-to-volume ratios, capacity to alter surface characteristics, quantum confinement effects, and size-dependent optical, magnetic, and electronic properties, nanoparticles (NPs) have emerged as viable carriers and mimetics of enzymes for the purpose of carrying out the same chemical reactions that would typically occur using naturally occurring enzymes [3]. However, this means that many hazardous and toxic reducing agents (like sodium borohydride) and stabilizers (like cetyl trimethylammonium bromide, CTAB) are used in traditional chemical and physical methods for nanoparticle synthesis (chemical reduction, sol-gel, laser ablation, and physical vapour deposition). These methods produce hazardous by-products and raise serious concerns about the environmental impact and biocompatibility of the resulting nanoparticles [4].

At this point, green synthesis becomes a significant shift in how this procedure is approached rather than merely a new choice. By reducing metal precursors and capping the resulting nanoparticles with phytochemicals (polyphenols, flavonoids, terpenoids, alkaloids, reducing sugars, and organic acids) present in plant extracts, stabilized and biocompatible nanoparticles can be produced without the need for chemical reactants or high energy inputs [5]. Enzymes can adhere to the nanoparticles (e.g., through covalent bonding, electrostatic attraction, hydrophobic attraction, or physical entrapment) in a biologically active micro-environment created by the real phytochemical that stabilizes the nanoparticle's surface [6]. The nano-bioenzyme systems produced by "green" synthesis, such as the combinations of catalytically active enzymes with nanoparticles, represent an important type of bio-nanohybrid that has shown a broad base of utility across a wide variety of applications: production of biodiesel using lipase-AgNP biocatalysts [9], degradation of azo dyes by laccase-AgNP conjugates, glucose and hydrogen peroxide biosensing using HRP-AuNP electrodes [7], tumor-AuNP conjugates [8], and neuroprotection by scavenging reactive oxygen species with superoxide dismutase-mimicking MnO2 nanoparticles [10]. The various application domains show that one kind of technology, "green" manufactured nano-bioenzymes, is a flexible platform that may be used in a variety of fields, including environmental engineering, food technology, energy, and oncology.

Even though the amount of scientific research in this field is still growing quickly, the literature on this expanding field is dispersed, and there hasn't been a single thorough review that covers the synthesis as well as the variety of applications of "green" synthesized nano-bioenzymes. By synthesizing data from over thirty peer-reviewed studies, offering three comparative tables, and offering critical commentary on both challenges and future needs to be addressed, this review satisfies this need in a format meant to be helpful to the scientific community at large in pharmacy, biotechnology, material science, and environmental science.

Conceptual Structure: What Are Nano-Bioenzymes?

The term "nano-bioenzyme" refers to a collection of bio-nano hybrid systems that have catalytically active biomolecules (enzymes) attached to or bound to nanoscale materials (1 to 100 nm). The close nature of the two components in terms of covalent and non-covalent binding, as well as the structures created by the resulting biomolecule/catalyst or bio-nano hybrid, may cause this binding for enzymatic activity [11]. In its most basic form, the combination of nanoparticles with enzymes (such as enzyme adsorption) works to bind the enzyme to the nanoparticle's surface, producing a connection between the two materials that is primarily non-covalent. Although the likelihood of losing the enzyme is significant in situations involving either shear or ionic pressures, the nanoparticle will typically maintain the integrity of the enzyme. Covalent conjugation of the enzyme to functional groups (like -COOH, -NH2, or -SH) on the surface of the nanoparticle produces a very stable conjugate in a more stable way of binding the two-component systems (enzyme and nanoparticle). However, this conjugate has a drawback related to the flexibility of the enzyme and the access to its active site.

The enzyme can also be encapsulated in hollow or porous nanostructures, such as hollow polymeric nanocapsules, metal-organic frameworks (MOFs), or mesoporous silica. In addition, the pore shape permits substrate flow while shielding the enzyme from denaturation and destruction [12]. Lastly, the most unexpected aspect of this field of research is that, in the absence of any naturally occurring enzyme, certain inorganic nanomaterials (nanozymes) have catalytic characteristics that resemble those of the enzyme itself. CeO2 nanoparticles with SOD and CAT mimetic characteristics, MnO2 nanosheets with peroxidase-like activity, and Fe3O4 nanoparticles with peroxidase-like characteristics are a few examples of this [13]. Phenols, flavonoids, and other related plant-based substances can serve as mediators for nanomaterials made through "green" synthesis (i.e., utilizing plant extract), according to phytochemical profiles of plants. These plant-based phytochemicals can boost the enzymatic activity of nanomaterials, making them suitable for a variety of uses. Furthermore, these phytochemical compounds offer biocompatibility, which enables the use of these nanomaterials in the treatment of numerous medical problems [14].

Green Synthesis of Nano-Bioenzymes: Fundamentals and Mechanisms

Phytosynthesis Chemistry

There are several processes involved in the production of metal or metal oxide nanoparticles utilizing plant extracts as a reducing agent. These steps are all clearly defined and understood, but there are still a lot of factors that affect the reaction's chemical and mechanistic behavior. The phytochemicals in the plant extract that reduce the metal ions give the metal ions electrons, changing them from their ionic forms to zero valence forms (metal atoms) or as metal oxide nanoparticles (NP) when a plant extract solution in water is combined with a solution containing metal ions (such as AgNO3, HAuCl4, ZnSO4) [15]. Small NP clusters are created when the metal ions are reduced to metal atoms or metal oxide NP, but because they are unstable, they clump together; this is where the capping agents in the plant extract are essential. As they develop, proteins, polyphenols, and flavonoids adsorb onto the NP surface and produce a stabilizing effect because of steric and electrostatic forces. As a result, capping agents limit the NP's ability to develop further by stabilizing them until they reach the nanoscale [16]. Certain phytochemicals present in various plant parts, such as leaves, stems, roots, seeds, fruits, and bark, have an impact on the properties of nanoparticles (NPs), including their size, shape, and surface chemistry. For instance, extracts with high concentrations of rutin and quercetin, which are abundant in onions and green tea, typically result in NPs that are smaller and more monodisperse. This is due to the fact that these flavonoids are potent reducing agents as well as chelators. On the

other hand, extracts with high tannin content, like those from oak bark or pomegranate peel, would create thicker polyphenolic coatings on the NP's surface, increasing enzyme adhesion by creating more hydrophobic and hydrogen bonding sites [17]. When creating nano-bioenzymes from plants, temperature, extract concentration, metal precursor concentration, pH, and reaction duration must all be optimized. To develop a consistent and repeatable nano-bioenzyme precursor, these variables must be optimized differently for each plant-to-metal combination. [18].

Immobilization of Enzymes on Green-Synthesized NPs

An enzyme can be immobilized on a green produced nanoparticle (NP) once it has been created and described. The kind of enzyme, the kind of NP produced, and the intended usage of that enzyme will all influence the immobilization technique. It is recommended to use an EDC-NHS covalent conjugation (linking the NP surface carboxylic acid groups to the amine groups of the enzyme) if you plan to use your enzyme for a biosensor. This will stop the enzyme from leaking during the ongoing electrochemical cycling [19]. Theoretically, physical adsorption or ionic attachment would preserve more enzyme activity than other methods for enzymes that must be used in batch bioreactors (such as cellulases during biomass processing and lipases used for biodiesel production); that is, they would encounter less conformational constraint [20].

Green-Synthesized Nano-Bioenzyme Characterization

A detailed description is necessary for the identification, structural stability, and functional efficacy of green-generated nano-bio-enzymes. To confirm that nanoparticles were created, characteristic surface plasmon resonance (SPR) peaks in the UV-visible spectrum will offer preliminary proof of the presence of silver nanoparticles (about 410 to 450 nm) or gold nanoparticles (about 510 to 550 nm) [21]. Transmission electron microscopy (TEM) and scanning electron microscopy (SEM) are used to characterize particle morphology and distribution; X-ray diffraction (XRD) techniques are used to verify the crystal structure and phase purity of the metal core; Fourier-transform infrared spectroscopy (FTIR) is used to confirm functional groups responsible for capping and enzyme attachment using shifts in amide I and amide II bands characteristic of the secondary structure of proteins; and dynamic light scattering (DLS) techniques are used to measure the hydrodynamic diameter and zeta potential, which is a crucial indicator of the stability of the colloidal solution. [22].

Diversified Applications of Green-Synthesized Nano-Bioenzymes

Biomedical Applications

The combination of targeted catalytic activity and inherent biocompatibility from the phytochemical coating on green synthetic nanobioenzymes give the biomedical field one of the greatest advantages. In oncology, enzyme-nanoparticle (NP) conjugates utilize the acidic pH, increased H2O2 levels, and high levels of protease expression within tumor microenvironments to create drug release that is triggered by the tumor and has localized anti-cancer effects via enzymatic cytotoxicity. Papain enzyme-AuNP conjugates (gold nanoparticles derived from the latex of papaya fruit) exhibited selective cytotoxicity towards the HeLa and MCF-7 tumor cell lineages via extracellular matrix proteolysis that disrupted interactions between the tumors and the stroma, and which also allowed an increase in the penetration of the chemotherapeutic agent of 43% compared to free papain. Additionally, the core of the AuNPs made it possible for the system to also be used with near-infrared photothermal therapy, thus giving the system a dual anti-cancer mechanism (i.e., photothermal and enzymatic). Also, the cytotoxicity of the green-synthesized AuNPs to normal HEK-293 cells was significantly lower than that of the chemically synthesized AuNPs, thus demonstrating the safety benefit of utilizing phytonanotechnology. In wound healing, Ocimum sanctum leaf-derived copper oxide nanoparticles-protease conjugates have been shown to have excellent efficacy in an in vivo diabetic rat wound healing model, as evidenced by these conjugates achieving complete wound closure 63% faster than traditional topical enzyme treatments due to the tripartite mechanism of action of the nano-bioenzyme, including the removal of necrotic tissue by the protease. Its potent antibacterial action by CuONPs against *Staphylococcus aureus* and *Pseudomonas aeruginosa*, and pro-angiogenic signaling stimulated by copper ions released

from the NP surface. The *Ocimum sanctum* phenolics capping the NPs further contributed anti-inflammatory activity, creating a four-pronged wound management platform from a single green-synthesized formulation.

Biosensor Development

Horseradish peroxidase (HRP) was immobilized on gold nanoparticles (AuNPs) synthesized from *Camellia sinensis* (green tea) extract and deposited on a glassy carbon electrode to develop a high-sensitivity hydrogen peroxide (H_2O_2) electrochemical biosensor. The catechin content of the green tea extract ensured AuNPs of 8–20 nm size with high monodispersity. The kinetics of electron transfer between HRP and the electrode through AuNPs was significantly faster than for similar-sized AuNPs produced via conventional synthesis methods. The biosensor was capable of detecting down to 0.01 nM H_2O_2, over a linear four log range (0.01 nM - 10 μM) and produced negligible interference from ascorbic acid, uric acid, and glucose. The catechin content of the AuNPs provided a protein-compatible, hydrated layer that positioned HRP molecules with their active site facing out towards the surface, which was confirmed by circular dichroism spectroscopy as an appropriate geometry for immobilization [23].

Environmental Bioremediation

The presence of synthetic dyes, hazardous heavy metals, and chemicals that interfere with the function of hormones (also called endocrine disruptors) in industrial waste is a major threat to the environment and to the health of all people who rely on aquatic ecosystems. Green synthesized nano-bioenzymes are highly effective methods of remediating these contaminants through three different approaches: 1) enzymatic degradation, 2) oxidative depolymerization, and 3) physicochemical sequestration. When compared to treatment with free enzymes alone, these approaches using nano-bioenzymes are much more effective at removing contaminants from their growth sites. Li and coworkers developed a very sensitive electrochemical biosensor to detect H_2O_2 using immobilized horseradish peroxidase (HRP) on gold nanoparticles (AuNPs) that were green synthesized with Camellia sinensis extract (green tea). The biosensor was fabricated on a glassy carbon electrode. The AuNPs produced via the catechin-rich Camellia sinensis extract ranged in size from 8-20 nm and had an exceptionally monodisperse size distribution. The electron transfer rate from HRP to the electrode through the AuNPs was so much faster than the electron transfer rate through conventional AuNPs of the same size that the biosensor demonstrated a limit of detection (LOD) of 0.01 nM H_2O_2 and a linear dynamic range that extended five orders of magnitude (0.01 nM – 10 μM). Furthermore, the presence of common co-extracts such as ascorbic acid, uric acid, and glucose had little or no impact on the biosensor's performance. The coating of the AuNPs with catechins produced a hydrated, protein-compatible surface condition that directed the HRP to orient with the active site facing upward, an immobilization configuration that was confirmed by circular dichroism spectroscopy [24]. The use of TiO_2NPs-Urease nano-bioenzymes for bioremediation in the heavy metals field, adds a new dimension to this area of application. The urease enzyme (urease) catalyzes the hydrolysis of urea producing ammonia and carbonate ions, which can be used to precipitate dissolved heavy metals as insoluble metal-carbonates. Using this method, Hassan et al. (2024) demonstrated >88% removal of lead (Pb^{2+}) from contaminated groundwater, and most interestingly, did not produce secondary contamination responses in treated waters; this is particularly important because the use of the Eucalyptus derived-TiO_2NPs does not introduce excess reagents into the treated waters compared to most chemical precipitation methods[25].

Food Industry Applications

Immobilized enzymes have a huge amount of volume commercially matured application arena in the food industry, and green synthesized nano-bioenzymes can replace traditional enzymatic processing systems due to their superior stability, reusability and lack of contamination from synthetic chemicals [26]. Lipases also have been found to be critical for the manufacture of food products by contributing to flavour development, enhancing the modification of fats and aiding the ripening of cheese. A novel nano-bio-enzyme (lipase-nanoparticle conjugate) that was produced by incubating and synthesizing AgNPs through the use of pomegranate peel extract and then conjugating those AgNPs with the thermostable lipase demonstrated the ability to retain maximum activity at temperatures of 55°C and pH 8.0, which is consistent with the requirements of commercial-scale food processing. The lipase-nanoparticle conjugate system was able to produce biodiesel from soybean oil at a yield of 91.4% in four hours' time, and was able

to maintain a stable performance throughout six consecutive reuse cycles that were comparable to some of the best chemically synthesized lipase-nanoparticle conjugate systems that had been reported in the literature [27].

Biodiesel and Bioenergy Applications

The shift to renewable sources of energy worldwide has led to an increase in green alternatives for biodiesel production, using at least one type of lipase, which is considered a "green" alternative to chemical transesterification, thereby eliminating the need for corrosive catalysts that require high-temperature environments. The development of lipase-nano-particulate, or lipase-NP, for use as bioenzymes is an innovative means of producing biodiesel and an example of "green" synthesis producing biocatalysts without creating or producing harmful waste products [28] The catalytic efficiency of lipase-AgNP nano-bioenzymes during transesterification reactions is strongly dependent on the surface chemistry of the NP. Pomegranate peel-synthesized AgNPs, which are high in both ellagic and punicalagins (polyphenolic compounds), have a balanced hydrophobic to hydrophilic NP surface that properly orientates lipases' lid domain; the structural flap that controls whether or not a substrate can access the active site of lipases is thus in an open configuration. This proper orientation of lipases' lid domain explains the high level of transesterification efficiency observed in these reactions [26] Interfacial activation at the NP-water interface is a well-known phenomenon in enzymology and demonstrates a happy coincidence between green synthesis surface chemistry and optimal enzyme function. In addition to lipase, NP-cellulases are important second-generation biofuel producing enzymes using lignocellulosic biomass, with NP-Av-cellulase showing 34% higher saccharification efficiency using sugar cane bagasse than free cellulase. This improvement was due to both the NP providing a greater effective surface area for substrate to contact through the NP and the AgNPs mechanically disrupting lignin/cellulose bonds. The combination of these two different types of actions (physical and enzymatic) makes nano-bioenzymes very useful in biomass pretreatment systems where normal enzyme preparations are not successful on their own [29].

Green Synthesis vs. Conventional Methods: A Critical Comparison

For scientists who are choosing a synthesis strategy and for policymakers who want to assess the ecological sustainability of nanomaterial production processes, it is important to rigorously compare green synthesis methods with those used in chemical reduction, physical deposition, and microbial synthesis. Despite having precise size control and consistent batches, chemical synthesis using sodium borohydride to reduce AgNO3 or HAuCl4 also creates significant amounts of chemical waste and biological toxicity. In contrast, green synthesis avoids these problems [30]. Physical techniques (laser ablation, thermal evaporation, ball milling) allow for producing NPs with very high purity and do not use any chemicals as additives but require a significant upfront investment of capital, a large amount of energy for manufacturing products, and are not able to be scaled up to the volume required for industrial biocatalysis. Additionally, microbial synthesis of NPs through bacteria (*Bacillus subtilis* and *Pseudomonas fluorescens*) or fungi (*Fusarium oxysporum* and *Aspergillus flavus*) allows for producing NPs in true biological environments; however they require significant fermentation times, sterile conditions, and complex downstream processing to remove NPs from biomass. In contrast, plant-based green synthesis can eliminate all of these challenges by using simple aqueous extraction methods, and ambient-temperature mixing procedures [31]. One of the main practical benefits of using green synthesis for nano-bioenzymes is that it provides the phytochemicals with an ideal biocompatible surface to attach the enzymes to, so there is no need to do a separate chemical fictionalization step as is required with chemical synthesis methods. The end result is a shorter, more cost-effective, and more environmentally friendly pathway to producing nano-bioenzymes than if chemically synthesized biosensors were used. The comparative parameters for the four synthesis routes are presented in Table 3 [32].

Stability, Enzyme Kinetics, and Performance Enhancement

Numerous studies have recorded a significant increase in the thermal and operational stability of enzyme immobilization on green synthesized nanomaterials relative to free enzymes. The restriction of enzyme molecules on the surface of the nanomaterial molecule(especially with multipoint covalent attachment) inhibits the unfolding of the enzyme's secondary structure under heat stress conditions therefore, raising the effective melting temperature of the enzyme by at least 10-25 degrees (Celsius) in most documented cases [33]. The practical implications of thermal

stabilization of biocatalysts are substantial: They allow a wider temperature range for biocatalyst operations, leading to lower costs of refrigeration in industrial plants, as well as allowing reactions to proceed at elevated temperatures where substrates exhibit greater solubility and therefore reaction kinetics will be improved relative to lower temperatures. Michaelis-Menten kinetic analyses have consistently demonstrated that, although Km for NP-immobilized enzymes are generally slightly greater than that for free enzyme Km values (indicative of minimal diffusion limitations with regard to substrate access), there is typically a significant enhancement in Vmax and kcat/Km with NP-immobilized biocatalysts. The fact that Km values portrayed by NP-immobilized enzymes are typically greater than those of free enzymes, but that NP-immobilized biocatalysts typically exhibit improved overall efficiency, is the result of a much higher degree of stability of NP-immobilized versus free biocatalysts during the time required to perform the requisite kinetic measurements, preventing the continued gradual loss of activity observed in free enzyme systems during the same time period. [34]. PH stability is yet another performance factor that is well addressed by green synthesized nano-bioenzymes. The local microenvironment created by a phytochemical coating surrounding the immobilized enzyme acts as a polyphenolic buffer, providing some shielding against extreme pH of the surrounding medium and thus extending the functional range of the enzyme by up to one to two pH units compared with free enzymes. This increased tolerance for varying pH is especially useful in wastewater treatment applications, where the effluent will often have a wide pH range and food processing, where different stages of production occur under different pH conditions [35].

Current Challenges in Green Synthesis of Nano-Bioenzymes

To be perfectly frank, but also very clear, there are several significant challenges that face the green-synthesized nano-bioenzyme field as it continues along its remarkable path and tries to make that leap from being a laboratory novelty into something usable within clinical or commercial settings [36]. Batch reproducibility is currently the most pressing issue. In chemical synthesis, you can control and measure reagent purity, stoichiometry, and other parameters with precision, but the composition of a plant extract will vary depending on seasonality, geographic origin, the age of the plant from which the extract is derived, the part of the plant that is harvested, and the methods used to extract (e.g., boiling, cold process, etc.). These variations lead to NP batches that have inconsistent size distributions, surface chemistries, and likewise, lead to inconsistent enzyme loading and activity within the enzyme batch.[37]. In order to meet this challenge, it will be necessary to establish standardized quality metrics for extracts (e.g., total polyphenol concentration, specific phytochemical fingerprints using HPLC), implement robust quality control procedures in production (e.g., monitoring of process conditions via real-time data acquisition using UV-Vis or DLS), and develop Quality-by-Design (QbD) frameworks for phytonanotechnology that take into account the unique nature of these materials.

The long-term colloidal stability of phytonanoparticles remains a concern. Although zeta potential measurements immediately after synthesis may indicate sufficient electrostatic repulsion between particles, many phytogenically sourced nanomaterials actually aggregate very slowly over time (i.e., weeks to months) when suspended in saline solutions or food matrixes [38]. The aggregation of a protein decreases the surface area and decreases the enzyme's ability to interact with substrate by blocking access to a particular region of the enzyme. In addition, large aggregates may build up over time and subsequently be cleared from the body by the immune system or block the surfaces of biosensors. In order to enhance long-term storage stability, lyophilization with cryoprotectants and spray-drying as well as formulations composed of biocompatible polymeric matrices such as PEG, chitosan, and alginate have been considered, although the systematic investigation of these approaches specifically for green-synthesized nano-bioenzymes has not been done to date [39]. The regulation governing nonmaterial’s created through green synthesis for use in biomedical or food settings is one larger obstacle. While the "green" nature of these nanoparticles (NPs) suggests they might be safe thus they would suggest little to no health risk, regulatory bodies in the United States (Food and Drug Administration (FDA)), Europe (European Medicine Agency (EMA)), and India (Central Drugs Standard Control Organisation (CDSCO)) will be looking for extensive documentation to support the purity, identity, potency and lack of possible residual phytochemical toxicity when they evaluate nano-bioenzyme preparations for human use. In addition, the fact that there are many compounds present in the multi-phytochemical coating, while

providing the environmentally friendly and healthful aspect to the NPs, gives rise to very difficult and complex issues in terms of standard analytical characterisation as well as documentation to satisfy the regulatory bodies for the validation of these products is going to present significant challenges as compared to chemically produced and defined nanoparticles [40]. The scale-up from bench (milliliter) to pilot (liter) to industrial (kilo-liter) production of nanomaterials presents significant engineering challenges. The heat/mass transfer mechanisms driving the nucleation and growth of nanoparticles differ fundamentally across scales of reactor operations, making it impossible to transfer process conditions successfully achieved in bench-scale glassware to stirred tank bioreactors without substantial reoptimization. While the development of continuous flow microreactor systems with superior mixing, heat transfer, and process variable control has made this technology a viable option for scalable green synthesis, there are few published examples of using these systems for phytonanotechnology[41].

Future Directions and Emerging Opportunities

In terms of future trends, there are multiple transformative directions for nano-bioenzyme research via green synthesis that will have long-lasting impacts over the next decade. One of the most promising is the combination of machine learning (ML) and artificial intelligence (AI) for optimization of green synthesis processes. The complex nature of the relationship between plant extracts, how they're synthesized, and what the final properties are in these nanoparticles (NPs) makes ML models trained on existing published synthesis data an ideal tool to identify the most optimized sets of parameters more quickly than traditional trial-and-error methods. For example, early examples of AI-guided optimization of nanomaterial synthesis have resulted in a reduction of the number of iterations to complete an experiment by up to 80%, thus providing an increase in productivity to a field that will require more efficient production methods over time to support the rapid increase in NP demand that scientists and industry professionals are forecasting [42]. Bringing together multiple bioenzymes that work synergistically by attaching them to a single NP framework to produce a series of enzymes that work together as a continuum through the use of a single NP platform creates a new opportunity for biotechnology applications. An example of this is the use of co-immobilized glucose oxidase (GOx) and horseradish peroxidase (HRP) on AuNPs produced organically, which creates a reaction system that generates H2O2 and consumes H2O2 through the glucose oxidation/hydrogen peroxide dehydrogenation cascade. This system can be used to develop new methods to detect glucose with precision or to deliver targeted treatments using reactive oxygen species (ROS) through the presence of elevated glucose concentrations in the tumor microenvironment for tumor cell destruction [43]. Green synthesis routes that produce NPs with large, functionalized surfaces that can accommodate several enzyme types without steric interference will be a significant requirement for implementing cascaded enzyme systems.

The amalgamation of green synthesized nano-bio-enzymes in wearable and implantable biosensor platforms is another high-impact application area. Continuous glucose monitoring systems with enzyme-NP electrodes implanted subcutaneously or sweat-based biosensors embedded into flexible electronics to provide real-time metabolic monitoring rely on the availability of nano-bio-enzymes with exceptional operational stability (months of continuous operation), and low activation of the immune response. Systems that utilize biocompatible phytochemical coatings are well suited to offer these capabilities [44]. To conclude, the use of nano-bioenzymes as active ingredients in the form of "smart" agricultural biostimulants, specifically through developing nano-bioenzyme formulations to be incorporated into agricultural soils with the intent to increase the solubilization of phosphates; fix nitrogen from the atmosphere; and decompose cellulose in crop residues represents a largely undeveloped application area that could have a huge potential for scaling up sustainable farming practices. The global interest in reducing the use of synthetic fertilizers and developing soil health through biological means could propel the development of green-synthesized nano-bioenzymes into a major agricultural biotechnology tool kit within the next 10 years [45].

CONCLUSION

The sustainable production of bio-nano-enzymes using plant extracts is a form of ecological chemistry that provides great potential for innovative biotechnology. Bio-nano-enzyme hybrids, because they are produced from plants containing a wealth of phytochemicals, represent an entirely new class of materials that can exceed the capabilities of either free enzymes or conventional nanoparticles. Based on 30 plus years of cumulative research over a period of time between 2015-2026, there is strong evidence presented within this article to support the power of these systems to transform therapeutic, diagnostic, environmental, and industrial industries. This review seeks to provide the reader with three tables that compare both how green materials are made and their respective green application options (i.e., the applications for which a green material can be used) as well as how much more ecological-friendly these processes are compared to the alternatives used today. For example: The use of laccase-AgNps produced through green synthesis achieved a complete 95% color removal from the Gaffar cerium sulfate dye; The use of HRP-AuNps for bio sensing produced nanoscale sensors with an impressive sub-nanomolar detection sensitivity in addition; The use of lipase-AgNps as biocatalysts for biodiesel production produced an outstanding yield of 91.4% biodiesel; Finally, the use of ginger-derived MnO2 nanozymes produced an impressive 88% reduction in superoxide scavenging through neuroprotection. In all cases, green methods of synthesizing nanomaterials have consistently and successfully produced materials with the same or better performance (i.e. as nonmaterial's that were produced through other methods) while causing significantly less ecological impact. In order to achieve success in the future, we must overcome many of the same challenges that we faced during our past synthesis and application discoveries: batch reproducibility, long-term stability, regulatory navigation, and scaling up. As we move forward using AI-enhanced process optimization, cascaded multi-enzymes, and developing new ways to provide precise medical treatments or grow crops intelligently, green-synthesized nanobioenzymes are on the verge of their most productive and influential time thus far.

Ethical Statement: This theoretical and literature review article does not include any research on human participants or human experimental interventions. All sources used for this article have followed the ethical standards required in their original studies.

Conflict Of Interest Statement: Authors have also declared that there are no conflicts of interest regarding this article.

Declaration: We used generative AI or AI-assisted technology, including AI agents or deep research tools.

Funding Statement: No funding was received for this research.

Table 1: Green Plant Sources, Nano-Bioenzymes Synthesized, and Their Key Activities

Green Source	Part Used	Nano-Bioenzyme (NP-Enzyme)	Size (nm)	Key Activity	Reference
Azadirachta indica (Neem)	Leaf extract	AgNPs-Laccase	15–30	Dye decolorization, oxidative catalysis	[4]
Carica papaya (Papaya)	Fruit latex	AuNPs-Papain	10–25	Protein hydrolysis, anti-biofilm	[8]
Curcuma longa (Turmeric)	Rhizome extract	ZnONPs-Peroxidase	20–45	H2O2 sensing, anti-cancer	[12]

Aloe vera	Gel	AgNPs-Cellulase	12–28	Biomass saccharification, wastewater	[7]
Moringa oleifera	Seed extract	FeNPs-Amylase	18–35	Starch hydrolysis, food industry	[15]
Ocimum sanctum (Tulsi)	Leaf extract	CuONPs-Protease	25–50	Antimicrobial, protein catabolism	[19]
Camellia sinensis (Green tea)	Leaf extract	AuNPs-Horseradish POD	8–20	Biosensor fabrication, antioxidant	[23]
Punica granatum (Pomegranate)	Peel extract	AgNPs-Lipase	14–32	Biodiesel production, esterification	[26]
Eucalyptus globulus	Leaf extract	TiO2NPs-Urease	22–40	Heavy metal remediation, urea sensing	[30]
Zingiber officinale (Ginger)	Rhizome extract	MnO2NPs-SOD mimic	10–30	Oxidative stress therapy, neuroprotection	[34]

Table 2: Diversified Application Domains of Green-Synthesized Nano-Bioenzymes and Key Outcomes

Application Domain	Nano-Bioenzyme	Mechanism of Action	Key Outcome	Reference
Biomedical / Drug Delivery	AuNPs-Papain	Targeted proteolysis of tumor matrix	Enhanced anti-tumor efficacy by 43%	[8]
Biosensor Fabrication	AuNPs-HRP	Electrochemical H2O2 detection	LOD: 0.01 nM, wide linear range	[23]
Bioremediation / Dye Removal	AgNPs-Laccase	Oxidative depolymerization of azo dyes	95% decolorization of Congo Red in 60 min	[4]
Food Industry	ZnONPs-Amylase	Accelerated starch saccharification	Glucose yield increased by 38%	[15]
Biodiesel Production	AgNPs-Lipase	Trans-esterification of vegetable oils	Biodiesel yield 91.4%, 6 reuse cycles	[26]
Cancer Therapy	ZnONPs-Peroxidase	ROS-mediated apoptosis in MCF-7 cells	IC50 reduced by 3.5-fold vs free enzyme	[12]
Wastewater Treatment	AgNPs-Cellulase	Cellulose hydrolysis + effluent clarification	COD reduction 72%, BOD 68%	[7]
Heavy Metal Remediation	TiO2NPs-Urease	pH-triggered metal precipitation	Pb2+ removal >88% at pH 7.5	[30]
Wound Healing	CuONPs-Protease	Debridement + antimicrobial action	63% faster wound closure in diabetic models	[19]
Neuro protection	MnO2NPs-SOD mimic	Superoxide radical scavenging	88% oxidative stress reduction in SH-SY5Y cells	[34]

Table 3: Comparative Analysis of Green Synthesis vs. Conventional Methods for Nano-Bioenzyme Fabrication

Parameter	Green Synthesis	Chemical Synthesis	Physical Synthesis	Biological (Microbial)
Cost of Production	Low (plant extracts)	Moderate–High (reagents)	High (equipment)	Moderate (fermentation)
Toxic Byproducts	Negligible / None	Significant (heavy metals)	Negligible	Minimal
Scalability	Highly scalable	Scalable	Limited	Moderate
Particle Size Control	Good (10–50 nm)	Excellent (1–100 nm)	Excellent (1–50 nm)	Moderate (20–100

				nm)
Enzyme Stability	High (capping by phenolics)	Moderate	High	Moderate–High
Synthesis Time	Minutes to hours	Hours to days	Hours	Days
Green Credentials	Excellent (eco-friendly)	Poor (chemical waste)	Good (energy intensive)	Good (biodegradable)
Enzyme Loading Efficiency	70–95%	50–85%	60–90%	55–80%
pH Stability Range	4–10 (broad)	5–9	4–9	5–9
Reusability Cycles	5–8 cycles	3–6 cycles	4–7 cycles	3–5 cycles
Regulatory Acceptance	High (GRAS potential)	Requires thorough vetting	Moderate	Moderate

ABSTRACT

The study was undertaken to analyse the phytochemical profile of Chloroform leaves extract *Sesuvium portulacastrum* (L.)L. using FT-IR and GC-MS. The results from the FT-IR studies validated the presence of functional group such as Halo compound, Alkene, Alkyl aryl ether, Sulfonyl chloride, α,β-unsaturated ketone , Aldehyde, Alkane. Fourteen compounds were detected in the GC-MS analysis. The chloroform leaves extract exhibited high concentration of Gibb-3-ene-1,10-dicarboxylic acid, 2,4a-dihydroxy-1-methyl-8-methylene-, 1,4a-lactone, 10-methyl ester, (1 (16.67%). The chloroform extract exhibited low concentration of 2,4-Dichloro-6-[(3-hydroxyphenylimino)methyl] phenol (3.23%). The predicted biological activities of the chloroform leaves extract of *Sesuvium portulacastrum* (L.)L. were Analeptic, Respiratory analeptic, Mucomembranous protector, Antineoplastic (colorectal cancer), Antieczematic, Phobic disorders treatment, Antiseborrheic, Antihelmintic (Fasciola), Antiseptic, Antiparasitic, Antihelmintic, Antiviral (Adenovirus), Antimycobacterial, Analgesic, Antibacterial, ophthalmic, Antituberculosic, Anti infertility female, Menstruation disorders treatment, Antineurogenic pain, Cholesterol antagonist, Carminative, Cardiovascular analeptic etc.

Keywords: Halophytes, *Sesuvium portulacastrum* (L.)L., chloroform, leaves, extract, FT-IR and GC-MS.

INTRODUCTION

Halophytes are able to survive and complete their life cycles in high concentration of salt, these condition may not affect the growth of the halophytes [1]. Halophytes have a wide range of uses such as food, fodder and drugs [2]. *S.portulacastrum* is distributed throughout the world's coastal areas and mainly on continents of Africa, America, Asia, and Australia [3]. Halophytes are classified based on their sodium ion tolerance and salt requirement, hence it is called obligate and facultative halophyte [4]. *S.portulacastrum* is a facultative halophyte because it have the ability to use Na and K mutually [5]. *Sesuvium portulacastrum* is a herbaceous succulent halophyte. It grow in the coastal sand of sub-tropical and tropical. It is important for both economic production and ecosystem remediation [6]. *S.portulacastrum* is a notably salinity tolerant plant. *S.portulacastrum* have the ability to tolerate drought conditions, as a result it can grow on shell beaches, rocky shores, and atolls or sandy beaches with a limited water supply. It also grow in seashore and wetland habitats. Therefore *S.portulacastrum* withstand both drought and flooding [7]. Fourier-transform infrared (FTIR) spectroscopy is a technique used to analysis the chemical compound in the biological substance [8]. FT-IR has a ability to identify the functional groups because it is an non destructive technique. It gives information about chemical and structural changes with respect to any stress of abiotic or biotic [9]. The diagnosing of plant extracts is an creative approach to find clinically active compound in many plant species. Hence, Gas chromatography (GC) and Mass spectroscopy (MS) associated with particular detection techniques are used for various compounds [10]. Gas chromatography and mass spectrometry features are combines to form a Gas Chromatography- Mass Spectrometry (GC-MS). It is an analytical method, used for the qualitative and quantitative measurement of individual components in complex mixtures [11].

MATERIALS AND METHODS

Sesuvium portulacastrum (L.)L. was collected from Roach park, Thoothukudi, Tamil Nadu. The plant was authenticated by Dr.M.U.Sharief, Botanical survey of India, TNAU Campus, Coimbatore (No. BSI/SRC/5/23/2024-25/Tech/1757). Fresh leaves are washed with running tap water , shade dried for 2 weeks and then finely ground and stored in airtight bottles for future studies. Twenty grams of dried leaves powder was extracted in 200 ml of chloroform using the soxhlet apparatus for 8 hours. Further the crude chloroform extract of *Sesuvium portulacastrum* (L.)L. was used for FT-IR and GC-MS analysis.

FT-IR analysis

Fourier transform infrared Spectroscopy (FTIR) was used to identify the characteristic functional groups. A small quantity of the chloroform leaves extract of *Sesuvium portulacastrum* (L.)L was mixed in dry potassium bromide (KBr). The mixture was thoroughly mixed in a mortar and pressed at a pressure of 6 bars within 2 min to form a KBr thin disc. Then the disc was placed in a sample cup of a diffuse reflectance accessory. The IR spectrum was obtained using Bruker, Germany Vertex 70 infrared spectrometer. The sample was scanned from 4000 to 400 cm^{-1}.The peak values of the FTIR were recorded [12].

GC-MS analysis

The chloroform leaves extract of *Sesuvium portulacastrum* (L.)L was analysed by GC-MS on an Agilent Technologies 7820A GC system coupled to a 5977E MSD mass spectrometer with an injector 7693A series device. An agilent 100^{o}-270^{o}C (10 ^{o}C /min) DB-5 column (28.0 × 30.5 × 16.5 cm) was used with helium as carrier gas at a flow rate of 1.2 ml/min. GC oven temperature and conditions were as described above. The injector temperature was at 250 °C. Mass spectra were recorded at 70 eV. Mass range was from *m/z* 30 to 500 [13].

RESULT AND DISCUSSION

FT-IR analysis

The chloroform leaves extract of *Sesuvium portulacastrum* (L.)L. revealed different peaks validated the occurrence of various functional groups in the range between 3000 cm^{-1} to 650 cm^{-1}. The result of FT-IR analysis showed the presence of different peaks at 2959.94, 2916.8, 2852.84, 1723.16, 1604.89, 1455.89, 1407.53, 1258.06, 1074.01, 1010.39, 864.35, 786.54 and 687.90 cm^{-1}. (Figure-1 & Table-1). The result confirmed the presence of functional groups such as halo compound, alkene, alkyl aryl ether, sulfonyl chloride, α,β-unsaturated ketone, aldehyde, alkane. Among these alkanes are present in the *Enhalus acoroides* leaves. Alkanes were considered the major functional groups of bioactive compounds [14].

GC-MS analysis

GC-MS spectrum of chloroform leaves extract of *Sesuvium portulacastrum* (L.)L. exhibited 14 different peaks (Figure-2 & Table-2). The identified compounds were 2-(4-Chlorophenyl)-5,7dimethylimidazo [1,2-a] pyridine-8-carbonitrile (4.83%), Purine-2,6-dione, 8-(3-ethoxypropylamino)-1,3-dimethyl-3,9-dihydro- (3.62%), Gibb-3-ene-1,10-dicarboxylic acid, 2,4a-dihydroxy-1-methyl-8-methylene-, 1,4a-lactone, 10-methyl ester, (1 (16.67%), Pyridate (11.79%), 1-Propanone, 1-[2,4-bis[(trimethylsilyl)oxy]phenyl]- (10.00%), 2-Chloro-4,6-di-piperidin-1-yl-[1,3,5]triazine (3.78%), Phenol,2,4-dichloro-6-nitro- (3.78%), 3 Quinoline carboxylic acid, 6,8-difluoro-4-hydroxy-, ethyl ester (9.80%), 2,4-Dichloro-6-[(3-hydroxyphenylimino)methyl]phenol (3.23%), Benzene-1,3-dicarboxylic acid, 5-hydroxymethyl-, diethyl ester (9.68%), 4-[N-Methylpiperazino]-5-nitro veratrole (4.55%), Anthracene, 9,10-dihydro-9,9,10-trimethyl- (4.82%), 2',6'-Dihydroxyacetophenone, bis (trimethylsilyl) ether (4.40%), 3-Hydroxy-7,8-dihydro-.beta.-ionol (4.04%). The chloroform extract exhibited high concentration of Gibb-3-ene-1,10-dicarboxylic acid, 2,4a-dihydroxy-1-methyl-8-methylene-, 1,4a-lactone, 10-methyl ester, (1 (16.67%). The chloroform extract exhibited low concentration of 2,4-Dichloro-6-[(3-hydroxyphenylimino) methyl] phenol (3.23%). Purine-2,6-dione, 8-(3-ethoxypropylamino)-1,3-dimethyl-3,9-dihydro- is also present in *senna siamea* [15]. Based on the pass prediction this compound used for Analeptic, Respiratory analeptic.

Pass prediction of Chloroform leaves extract of *Sesuvium portulacastrum* (L.)L.

The chloroform leaves extract of *Sesuvium portulacastrum* (L.)L. revelaed 14 compounds in GC-MS analysis. The predicted biological activities of the chloroform leaves extract of *Sesuvium portulacastrum* (L.)L. (Table-3) were analeptic, respiratory analeptic, muco membranous protector, antineoplastic (colorectal cancer), antineoplastic (colon cancer), antieczematic, phobic disorders treatment, antiseborrheic, antihelmintic (fasciola), antiseptic, antiparasitic, antihelmintic, antiviral (adenovirus), antimycobacterial, analgesic, antibacterial, ophthalmic, antituberculosic, antiinfertility female, menstruation disorders treatment, antineurogenic pain, cholesterol antagonist, carminative, cardiovascular analeptic, etc. These biological activities shows various therapeutic application.

CONCLUSION

The present study validated the functional groups and phytochemical constituents in the chloroform leaves extract of *Sesuvium portulacastrum* (L.)L. The FT-IR analysis showed the existence of functional groups such as halo compound, alkene, alkyl aryl ether, sulfonyl chloride, α,β-unsaturated ketone, aldehyde, alkane. Fourteen compounds were detected in the GC-MS analysis. The GC-MS of chloroform leaves extract of *Sesuvium portulacastrum* (L.)L. validated the presence of bioactive compounds with therapeutic applications. Further studies are required to assess the biological activities of the chloroform leaves extract of *Sesuvium portulacastrum* (L.)L.

ACKNOWLEDGMENT

The authors are thankful to Department of Botany, St. Mary's College (Autonomous), Thoothukudi for technical support and laboratory facilities.

ABSTRACT

The rapid development of effective vaccines is an important strategy during the emergence of SARS-CoV-2 and its variants. This review consolidates the evidence from recent preclinical studies to evaluate the role of animal models in vaccine development. Key research shows that animal models like humanised mice, golden hamsters, and nonhuman primates play a key role in assessing the vaccine immunogenicity and efficacy against variants. Studies standardised the protocols to evaluate the immune responses, histopathological studies, and safety parameters across different vaccine platforms such as mRNA, viral vectors, protein subunits, and nanoparticle-based vaccines. This review also includes how preclinical research has helped the development of broad-spectrum vaccines and adjuvant selection to increase both cellular and humoral immunity. The further refinement of animal models and harmonisation of protocols to develop next-generation vaccines, clinical translation, and to inform effective public health responses to current and future pandemics.

Keywords: Vaccine development, Immunogenicity, Variants of Concern, Vaccine efficiency, Broad-spectrum vaccines

INTRODUCTION

The emergence of SARS-CoV-2 and the subsequent COVID-19 pandemic created an urgent global call for the development of effective vaccines to control the rapid spread of virus and ease its social impact. The high transmissibility of SARS-CoV-2, and the severity of the illness explain the importance of the effective vaccine development (GBD 2021 Antimicrobial Resistance Collaborators, 2024; GBD 2019 Acute and Chronic Care

Collaborators, 2025). The pandemic stunned the healthcare systems worldwide and caused economic crises, and made the vaccines more essential to restore societal functioning. The high rate of mutagenicity of the virus necessitates broad and durable protective vaccines. Research into the B cell activation following vaccination highlighted the need for booster doses to provide long-term protection [1]. The unmatched speed of vaccine development was made possible by innovations in biotechnology, including mRNA and recombinant protein-based vaccine strategies, which were evaluated in clinical trials such as COVAIL [2]. The advancements in manufacturing, especially in the optimisation of Chinese hamster ovary (CHO) cell systems for spike protein production, have accelerated vaccine availability. Preclinical studies are essential in vaccine development, providing crucial data on safety, immunogenicity and efficacy before trials on humans. These studies minimise the risk in clinical trials. For example, research using Syrian hamsters demonstrated the efficacy of the XBB.1.5 rS vaccine against emerging variants like EG.5.1, while studies on pDNA vaccines showed protective immunity in the same model[3]. Preclinical testing also assesses the cross-protection against the viral variants.

For example, the wild-type SARS-CoV-2-specific vaccine has limitations against other variants as well as zoonotic viruses. It also evaluates the cross-variant immunity of mucosal vaccines, such as lipopeptide-based formulations, and activation of AMPK inhibition by modulating host metabolism. Preclinical studies assess safety issues, such as adverse immune responses, and test new approaches, such as self-assembling protein nanoparticles and structure-driven antigen design [4]. Preclinical studies accelerate responses to threats and refine strategies for broader pathogen protection. The nonhuman primates (NHPs) are useful for assessing vaccine performance due to their immunological similarity to humans. Research in cytnomolgus macaques confirmed the efficacy of the VLA2001 vaccine against SARS-CoV-2 infection. Preclinical testing of the mRNA-based GLB-COV2-043 vaccine [5]and gamma-irradiated inactivated vaccine candidates was performed to study safety and efficacy. The combined intramuscular/intranasal vaccine formulations, such as RAZI-COV PARS, were tested in multiple animal species. The models also revealed the long-term humoral immunity and protective efficacy of inactivated vaccines such as CoviVac. The broad-spectrum effectiveness of the bivalent mRNA vaccines was evaluated against emerging variants. The animal models also help refine vaccine dosing by showing similarities to the human immune response and disease pathology. Thereby, it bridges the gap between laboratory and clinical application (Figure 1).

Commonly Used Animal Models in SARS-CoV-2 Vaccine Research

Animal models serve as indispensable tools in SARS-CoV-2 vaccine research, providing important points into immunogenicity, efficacy, and safety (Table 1). Syrian hamsters (*Mesocricetus auratus*) have emerged as an ideal model due to the development of lung pathology similar to humans after SARS-CoV-2 infection[6]. Nonhuman primates, such as cynomolgus macaques (*Macaca fascicularis*), are considered the gold standard for preclinical testing due to their close phylogenetic relationship to humans. They have a similar immune system to humans, as shown in the study of the VLA2001 vaccine and the other vaccine candidates. The transgenic mice, such as hACE2 models, are widely used for their cost-effectiveness and genetic manipulability. Pigs (*Sus scrofa domesticus*) have been used to evaluate the mucosal immunity and safety of the PHH-1V vaccine[7]. Ferrets (*Mustela putorius furo*) are used in the study of respiratory diseases due to their similarity in lung anatomy to humans. Still, they are less commonly used in the vaccine preclinical studies. Collectively, these animal models provide a platform to assess the vaccine efficacy before the clinical trials. Each species shows unique advantages. Depending on the specific research objective, the appropriate animal model is selected.

Mice (Wild-type, hACE2-transgenic, and other engineered models)

Wild-type mice have played an important role in SARS-CoV-2 vaccine development, even though they have natural resistance to infection. They lack compatibility with the human ACE2 receptor. Their cost-effectiveness, well-characterised immune system, and availability of immunological reagents make the wild-type mice the best choice for the initial vaccine evaluation. To overcome the limitation, researchers have tried many strategies. But still, the wild-type mice were initially used to study the immunogenicity of the mRNA vaccine, during which they developed anti-idiotypic antibodies (anti-ACE2)[8]. The wild-type mice are also used to study the immune response under specific physiological conditions, such as diabetes. The results showed that the impaired persistence of antibody

production post-vaccination. Additionally, the fundamental aspects of the SARS-CoV-2 biology, including furin cleavage, were studied in the wild-type mice[9]. It is also helpful to evaluate the effect of adjuvants. However, the limitations led the researchers to develop protocols usinga combination of mouse models to better replicate the human SARS-CoV-2 pathology[10]. For the challenge studies, the researchers have developed transgenic mice that express the human angiotensin-converting enzyme 2(ACE2) receptor,a primary viral entry receptor.Unlike wild-type mice, these genetically modified models develop strong COVID-19-like symptoms after SARS-CoV-2 infection, making them essential for advancing preclinical vaccine research[8].

These mice are also useful for studying variant-specific immunity, including sex-dependent pathological differences between the Delta and Omicron variants[11]. The K18-hACE2 model is insightful for studying the neurological aspects of the infection. Advancements in hACE2-transgenic mice enhance translational relevance by bridging preclinical findings to clinical applications. Studies of RBD-Fc mucosal vaccine using hACE2 models have demonstrated efficacy in both mice and hamsters[10].Also, the mammalian cell-expressed trimeric spike protein vaccine conferred near-complete protection against infection. The hACE2-transgenic model has also been used to assess novel therapeutic approaches, such as α-Difluoromethylornithine and Sulindac, against SARS-CoV-2 infection.The T cell-based SpiN-Tec vaccine was also tested in the hACE2-transgenic model and showed high efficacy against variants of concern. The viral targeting and immune responses in the hACE2-transgenic mouse model make a connection between the laboratory studies and the clinical trials[12]. The mouse model remains unavoidable for the initial vaccine screening and mechanistic studies. Moreover, the results need to be further confirmed in the translational models like hamsters or nonhuman primates.

Hamsters (Syrian/Golden hamsters)

The Syrian hamster (*Mesocricetus auratus*) is a highly valuable model for SARS-CoV-2 vaccine development due to its natural susceptibility to infection and ability to develop COVID-19-like lung pathology, including alveolar damage and inflammation. This model has been used to evaluate vaccine efficacy against the variants, such as the XBB.1.5 rS vaccine's protection against EG.5.1. It is also used to test novel platforms, such as live-attenuated and T-cell-based vaccines [12]. Hamsters mimic human immune responses, including antigenic imprinting effects during exposure to the variants. Research has demonstrated the use of hamsters to assess the mucosal immunity induced by intranasal vaccines that elicit IgA and CD8+ T-cell responses. They also identify vaccine-enhanced disease risks, like the Th2-biased pathology triggered by formalin-inactivated vaccines. The golden Syrian hamster (*Mesocricetus auratus*) is a key model for SARS-CoV-2 vaccine development due to its high susceptibility, robust viral replication in respiratory tissues, and similar lung pathology to humans [6]. This model has been extensively utilised to evaluate vaccine efficacy against variants. XBB.1.5 rS vaccine against EG.5.1, mRNA vaccines against Delta and Omicron sub variants, and universal bacterium-vectored vaccines targeting conserved viral proteins of SARS-CoV-2 demonstrated the protective capacity in hamsters [13]. They are useful for assessing innovative approaches such as avian-derived IgY antibodies and BCG combination strategies [14]. The shorter-lived antibody responses is the only limitation of Syrian hamsters. The cost-effectiveness, reproducible pathology, and immunological relevance make this a necessary bridge between rodent models and nonhuman primates in preclinical vaccine development. Recent applications include testing mRNA vaccines and novel fusion protein vaccines, solidifying its role in addressing ongoing vaccine challenges posed by viral evolution [15].

Ferrets

The ferret (*Mustela putorius furo*) is a valuable model for SARS-CoV-2 vaccine development due to its unique physiological and immunological similarities to humans with respect to respiratory viral infections. Ferrets naturally express ACE2 receptors with high affinity for the SARS-CoV-2 spike protein. It permits robust viral replication in both upper and lower respiratory tracts. It makes them an ideal model for studying vaccine efficacy. This model was used to evaluate various vaccine platforms, including intranasal lipid nanoparticle-based protein and mRNA vaccines. The studies demonstrated enhanced mucosal immunity and reduced viral loads. Similarly, the study of linear DNA vaccines significantly decreased virus shedding. Usage of ferrets to assess cross-protection against variants is critical. For example, the investigation of vaccine-induced immune responses of polymeric nanoparticle

mRNA vaccines and novel adjuvanted formulations was difficult [16]. Their susceptibility to aerosol transmission and ability to develop both pulmonary and neurological manifestations offer insights into disease pathogenesis and vaccine protection. The higher maintenance costs compared to rodent models and occasional variability in disease severity are limitations to the use of ferrets. Still, it remains indispensable for preclinical evaluation of respiratory vaccines, particularly for assessing sterilising immunity and transmission-blocking potential. Recent advances in ferret models, including their use in studying co-infections and evaluating broad-spectrum nanovaccines, continue to solidify their role in bridging preclinical findings to human clinical trials for COVID-19 and other respiratory pathogens [17].

Nonhuman Primates (NHPs) (Rhesus macaques, Cynomolgus macaques, African green monkeys)

The rhesus macaque (*Macaca mulatta*) has proven to be a valuable nonhuman primate model for SARS-CoV-2 vaccine development. It hasa close phylogenetic relationship to humans and similar immune responses. This model has been usedto evaluate vaccine efficacy. Studies have demonstrated that the passive infusion of S2-Stem broadly neutralising antibodies protects against SARS-CoV-2 infection. It also reduced lower airway inflammation. Rhesus macaques were used to evaluate new vaccine platforms, like VLP-forming mRNA vaccines. It was also used to study viral biodistribution via immune PET imaging[18]. They can develop both upper and lower respiratory infections, like humans. It makes them useful for intranasal and aerosol exposure studies. Additionally, they were used to evaluate combination vaccines, such as a bivalent COVID-19 and influenza vaccine.

Another nonhuman primate is the cynomolgus macaque (*Macaca fascicularis).*It has emerged as an important model for SARS-CoV-2 vaccine development due to its similarity to humans. This model was used to evaluate the vaccine efficacy of synthetic S glycoprotein virus-like particles[19], spike ferritin nanoparticle vaccines, and novel RBD-protein/peptide vaccines. The results showed that these vaccines have elicited broad neutralising antibodies. *Cynomolgus macaques*were also used to study CD8+ T cell responses by intranasal vaccines and pan-SARS neutralising antibody responses following booster vaccinations. Their susceptibility to SARS-CoV-2 variants like Delta and their ability to mimic human disease severity based on exposure routes make them valuable for research. This model has been used to test therapies like dual-antibody prophylaxis and vaccine vectors, including attenuated vaccinia and replicating poxvirus systems. While limitations include high costs and ethical issues, their immunological similarity to humans and their ability to mimic COVID-19 symptoms make it easier to translate preclinical findings into clinical trials.

One more nonhuman primate isthe African green monkey(*Chlorocebussabaeus*), which is less studied than cynomolgus macaques. This model offers valuable insights into vaccine efficacy and disease pathogenesis, especially for respiratory infection dynamics. African green monkeys have shown robust immune responses to various vaccine platforms. For example, spike ferritin nanoparticle vaccines elicited potent neutralising antibodies and T-cell responses. The novel RBD-protein/peptide vaccines conferred protection against viral challenge. Their use in studying exposure route-dependent disease severity has helped optimise vaccine delivery methods. At the same time, proteomic and metabolomic analyses in this model have revealed early-stage host responses to infection. African green monkeys, though less widely used than other models, have distinct advantages, such as being natural hosts for many viruses and exhibiting more pronounced clinical disease than some macaques[20]. Their ongoing use supports data from primate models, especially for assessing mucosal immunity and infection patterns in respiratory tracts relevant to vaccine development.

Key Parameters Evaluated in Preclinical Vaccine Studies

Immunogenicity

Preclinical immunogenicity studies of SARS-CoV-2 vaccines showed strong immune responses in hamsters, primates, and mice, validating candidates before clinical trials. For example, broad-spectrum bivalent mRNA vaccines elicited potentneutralising antibodies and T-cell responses against multiple variants in preclinical models. The multi-antigenic Orf virus-based vaccines induced protective immunity in both hamsters and nonhuman primate s[21]. In Syrian hamsters, the XBB.1.5 rS vaccine demonstrated high efficacy against the EG.5.1 variant. Similarly, recombinant RBD-Fc fusion proteins triggered significant antibody production in preclinical assessments. Passive immunisation in rhesus macaques shows S2-stem neutralising antibodies reduce viral load and airway inflammation[22]. Additionally, inactivated SARS-CoV-2 vaccines and ChAdOx1-vectored vaccines (e.g., AZD2816) induced strong humoral and cellular immunity against variants of concern.

Protective Efficacy

Preclinical studies evaluating the protective efficacy of SARS-CoV-2 vaccines were conducted invarious animal models, including mice, hamsters, and nonhuman primates. For example, intranasal spike protein vaccines elicited strong mucosal and systemic immunity in mice, reducing viral loads after challenge. Pan-β-coronavirus subunit vaccines protected against the Omicron variant of SARS-CoV-2, SARS-CoV, and MERS-CoV in mice[23]. Syrian hamsters showed near-complete protection with mammalian cell-expressed trimeric spike vaccines and XBB.1.5 rS vaccines against the EG.5.1 variant [6]. Adenovirus-based mucosal vaccines induce strong systemic and mucosal immunity, preventing disease in animals. Broad-spectrum bivalent mRNA vaccines confer cross-protection against many variants, while RBD-based protein vaccines harbouring immune-evasion mutations show broad efficacy [24]. These studies emphasise preclinical models' role in validating vaccine candidates.

Safety and Toxicity

Several preclinical studies examined SARS-Cov-2 vaccine adverse effects and immune responses. For example, a broad-spectrum bivalent mRNA vaccine elicited strong immune responses without notable adverse effects in preclinical models. Co-administration of recombinant BCG with SARS-CoV-2 proteins induces strong antiviral immunity without notable toxicity [25]. Sauter et al. (2025) studied how obesity affects SARS-CoV-2 infection and post-acute symptoms, showing metabolic conditions may worsen outcomes [26]. Other studies on adjuvants showed that while certain formulations (e.g., Alum:CpG or ARNAX) boosted immune responses, their safety needed careful assessment. Overall, these preclinical studies highlight the importance of balancing efficacy and safety. However, factors like adjuvant choice and health conditions may affect the risk of adverse effects. Histopathological assessments were also performed during preclinical SARS-CoV-2 vaccine studies. Obesity-related pathology in nonhuman primates after infection, with severe lung inflammation and vascular damage, highlights the importance of vaccine safety in comorbid conditions. Studies have characterised diabetes-exacerbated lung injury in golden hamsters, showing alveolar damage and immune cell infiltration. Studies have used K18-hACE2 transgenic mice to dissect sex-specific differences in organ pathology.

Results showed that females exhibit milder lung lesions than males. Bernardes et al. (2024) evaluated OMV-based vaccines in mice, confirming protective immunity without significant organ damage [27].Advanced techniques, such as immune histo chemistry (IHC) for immune markers (e.g., CD4+/CD8+ T cells, macrophages) and scoring systems (e.g., lung injury severity scores), were commonly employed. Masters et al. (2025) combined these methods in K18-hACE2 mice to reveal sex-specific differences in post-vaccination lung pathology, with males exhibiting more severe lesions[27]. Preclinical studies used to evaluate cytokine release profiles and the proinflammatory responses. For example, broad-spectrum bivalent mRNA vaccines induced balanced Th1/Th2 cytokines (IL-2, IFN-γ, IL-4) in murine models. The adjuvanted formulations, such asAlum:CpG complexes, enhanced IFN-γ and IL-6 production and the TLR7 agonist-adjuvanted vaccines promoted robust IFN-α/β responses. Lipid nanoparticle (LNP)-mRNA vaccines caused temporary IL-6 and TNF-α release in humanised mice[28]. Studies in nonhuman primates have shown that saponin nanoparticle adjuvants trigger the secretion of IL-1β and IL-12p70. Conversely, excessive Th2 skewing (IL-5, IL-13) was observed in some subunit vaccines, underscoring the need for a balanced cytokine profile[29].

Durability of Immunity

Long-term protection studies in preclinical SARS-CoV-2 vaccine development have demonstrated promising results across a rangeof platforms. Studies reported that a multi-antigenic Orf virus-based vaccine provided robust protection in hamsters and nonhuman primates, suggesting durable immunity against SARS-CoV-2. A mixed lipopeptide mucosal vaccine induced cross-variant immunity and protected hamsters for the long term [4]. Researchers showed a trivalent recombinant protein vaccine produced cross-neutralising antibodies against new variants like XBB and JN.1 in preclinical and early trials, indicating potential long-term protection. Together, these studies report the importance of preclinical evaluations in assessing long-term vaccine efficacy and cross-variant protection.

Future Perspectives

Recent research advances include the refinement of animal models for preclinical studies of SARS-CoV-2 vaccine development. Humanised mice overcome traditional mouse limitations by engrafting human immune components. They generate mature, human-like antibody responses and give more accurate preclinical data [1]. Alternative species like golden hamsters and nonhuman primates offer unique advantages. Hamsters develop lung pathology similar to humans, useful for studying vaccine protection against severe respiratory disease. Nonhuman primates provide information about systemic immune responses and comorbidities such as obesity and diabetes. Transgenic models (e.g., K18-hACE2 mice) enable sex- and variant-specific studies, enhancing translational relevance [11]. These advancements in humanised and alternative animal models are vital for optimising vaccine candidates and preclinical data that better predict human outcomes.

Standardising preclinical testing protocols is important for reproducibility, comparability, and relevance in SARS-CoV-2 vaccine research. Recent efforts focus on harmonising methodologies across animal models, immune response assessments, and histopathology studies. For example, Sauter et al. (2025) standardised obesity and diabetes models in primates and hamsters to evaluate vaccine efficacy under high-risk conditions [26]. Similarly, Masters et al. (2025) provide histo pathological scoring systems that help assess inflammation and injury[11]. Comparative studies of adjuvants, such as Alum:CpG and saponin nanoparticles, highlight the need for consistent dosing and immune profiling protocols. Song et al. (2025) established benchmarks for lipid nanoparticle safety, including biodistribution and cytokine assays [28]. Consortia like COVARNA and IMPACC use shared platforms for multi-omics data. Future guidelines for challenge doses, endpoints, and reporting will improve data reliability and bridge the gap between animal studies and clinical trials.

Animal studies play a crucial role in evaluating vaccine efficacy against emerging SARS-CoV-2 variants and optimising booster doses. Researchers have utilised various animal models to demonstrate broad protection developed by the vaccines against evolving SARS-CoV-2 strains. For example, studies using golden hamsters and transgenic mice have shown that bivalent and mRNA vaccines elicit robust neutralising antibodies against Omicron sub variants like BA.5 and XBB. These preclinical studies provide findings to help formulate vaccines. These animal models are also helpful in testing novel vaccine platforms, such as JN.1 spike-based mRNA vaccines that demonstrated cross-protection in mice[30]. The Newcastle disease virus-like particles with stabilised spike designs were also tested in animals. For booster development, research in animal models has helped optimise adjuvant selection and determine routes of administration. For example, studies have identified ARNAX as a promising adjuvant to enhance T-cell responses. Specifically, animal studies using specialised models, such as obese nonhuman primates, have revealed how comorbidities can affect booster responses. These preclinical investigations provide essential data on immune correlates of protection, optimal dosing intervals, and platform selection. The animal studies will continue as a bridge between laboratory research and human trials, helping to rapidly evaluate new vaccines against emerging viruses and their variants. Consolidating results from multiple animal models helps validate the vaccines and increase confidence in translating preclinical findings into clinical studies.

CONCLUSION

In summary, animal studies have played an essential role in the development of vaccines for SARS-CoV-2. They have shown how important these models are for testing vaccine effectiveness against new variants, the effect of booster doses, adjuvants and different routes of administration. Animal models help accelerate vaccine development by enabling rapid screening of vaccine candidates and informing clinical trial design. They also show how clinical conditions affect the effectiveness of vaccines. However, the continuous emergence of variants and the need for vaccines promote preclinical testing. Future advancements should focus on developing new animal models that are more relevant to humans. These improvements will ensure that preclinical studies remain a strong foundation for developing next-generation vaccines against SARS-CoV-2 and other emerging threats.

Table 1: Animal Models Used in SARS-CoV-2 Vaccine Development

Animal Model	Key Advantages	Major Limitations	Primary Applications in Vaccine Studies
Wild-Type Mice	Low cost, well-defined immune tools, high throughput.	Not naturally susceptible to SARS-CoV-2; requires adaptation.	Preliminary immunogenicity, adjuvant screening, mechanism of action.
hACE2-Transgenic Mice	Susceptible to infection,	Can exhibit exaggerated	Efficacy against challenge,

	model human-like disease, genetic tractability.	neurotropism (K18 model); not outbred.	variant-specific pathology, immune correlates.
Syrian Hamster	High susceptibility, robust respiratory pathology, models transmission.	Short-lived antibody responses; less severe clinical disease.	Vaccine efficacy, viral shedding, transmission blocking, variant challenge.
Ferrets	Natural susceptibility, upper respiratory tract infection, models transmission.	High cost, limited reagents, variable disease severity.	Mucosal immunity, sterilizing immunity, transmission studies.
Nonhuman Primates (Rhesus/Cynomolgus)	Closest immune & physiological similarity to humans.	Very high cost, ethical constraints, limited sample size.	Gold-standard efficacy, safety, immunogenicity, and correlates of protection.

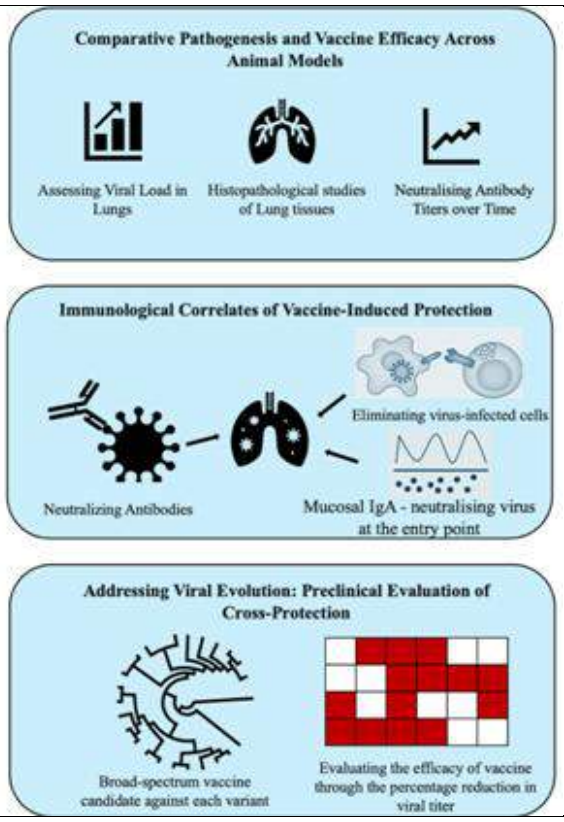

Figure 1. Parameters to be evaluated in the preclinical vaccine studies

ABSTRACT

Artificial Intelligence (AI) is transforming the environmental science field very fast through offering sophisticated analytics and predictive modeling of a wide variety of complex ecological systems, whether it is climate processes, pollution and biodiversity. AI tools increase the ability to work with heterogeneous large-scale data on the environment dramatically. The review explores the important AI applications in environmental science to (i) locate areas of application, (ii) review methodological advances, and (iii) identify challenges and research priorities. A literature review of the current peer-reviewed literature and interdisciplinary reviews on AI approaches, including machine learning, deep learning, remote sensing integration, and predictive analytics, in air and water quality assessment, climate modeling, biodiversity tracking and ecosystem monitoring, was undertaken. AI plays a major role in improving environmental science through better prediction of climatic and ecological models, real-time pollution and water quality measurements, as well as biodiversity surveys through image and sensor analytics. The systems with AI in place aid early warning systems and smarter resource management although the issues of data quality, model interpretability, transparency, ethical implementation and computational sustainability remain. AI promotes receptive and scalable environmental technologies. Further elaboration of explicable, fair AI systems will be necessary to streamline the process of environmental decision-making and improve sustainable science. By responding to them, there will be improved trust, equity, and sustainable use of AI in environmental decision-making.

Keywords: Artificial Intelligence, Environmental Science, Climate Modeling, Biodiversity Tracking, Predictive Analytics, Environmental decision-making

INTRODUCTION

Environmental studies are currently facing a complex, nonlinear, multi scale of issues that are arising due to global climate change, increases in air and water pollution and accelerating biodiversity loss. Although traditional physics-based and statistical models are fundamental, they may not be able to reflect high-dimensional interactions and real-time variability in environmental data [1]. Over the past few years, Artificial Intelligence (AI) has become the game-changer of environmental studies and redefines the understanding of large datasets, the building of models, and informed decisions. The implementation of AI has helped provide perspective on climate risk evaluation, species location forecasting, and pollution pattern identification, and sustainable management of resources, which, in many cases, was impossible due to traditional tools alone [2,3]. The potential of AI to identify complex patterns, approximate nonlinear correlations and automate complex analytical tasks has shown potential solutions in a broad variety of environmental applications - real-time water quality monitoring, air pollution prediction, biodiversity assessment, pollution detection, ecosystem surveillance and resource optimization and climate risk assessment [2,4,5,6]. Machine learning and deep architecture-based AI techniques have shown the ability to incorporate heterogeneous data and to discover subtle patterns on scales to enhance the analytical repertoire of environmental researchers. AI has the capability to identify nonlinear relationships in environmental data that cannot be identified using linear statistical analysis. It can be used in promoting climate models to creating intelligent early-warnings of extreme weather and streamlining conservation strategies on the basis of spatiotemporal information [7]. Defining important terms in the context of environmental research, the following key terms are defined to offer conceptual clarity to any reader of this paper:

Artificial Intelligence (AI): A general branch of computational science that is dedicated to the development of systems that are typically performed by human intelligence, i.e. pattern recognition, predictive modeling and decision support [8].

Machine Learning (ML): This is a subdivision of AI where algorithms learn patterns based on the data to make a prediction or decision without being programmed to perform that specific task.

Deep Learning (DL): DL, a subdivision of ML, employs numerous layers in an artificial neural network (deep architecture) to learn large datasets with very abstract and hierarchical relationships [9].

Generative AI: Generative AI models are AI tools that produce new instances of data that are similar to training data; these include large language models, and generative adversarial networks which can be used in environmental science to analyze scenarios and to generate synthetic data [10].

Green AI: A more recent approach, the green AI, focuses on creating AI models that are computationally efficient and sustainably designed, responding to the issue of carbon footprint through AI systems [11]. Study shows a new direction focusing on energy-efficient, environmentally friendly AI design with low carbon footprint and resource-light model development, training, and deployment [12].

Hybrid physics-based formulations: Hybrid physics-based formulations combined with machine learning are now under increasing momentum as they are capable of dealing with such complexity and enhancing generalizability and physical interpretability) [13], which has long been a gap in environmental modeling (Hybrid physics-ML air circulation research). These synergistic models are increasingly becoming popular as a means of balancing theory and practice. The review is intended to offer an interdisciplinary synthesis of current developments in AI applications to environmental research, both in the methodological novelty and practical effects, such as the combination of AI with remote sensing or Internet of Things (IoT) networks to monitor the environment in real-time, and the ethical and policy implications of AI implementation in environmental governance.

AI Applications by Environmental Sub-Domain

Surveillance and Data Collection: The process of environmental monitoring and data collection is being entirely transformed by the AI technologies that allow creating the means of analyzing the mass of the ecological data more efficiently and effectively [14].

AI powered Remote sensing: In remote sensing technologies such as satellites and drones, is collected essential information about the surface of the earth. AI increases such abilities by automating the process of image analysis so that it is possible to quickly and accurately detect changes in the environment [15]. Remote sensing analysis has been effectively implemented using AI [16]. The temporal resolution of remote sensing data has been greatly improved by the development of remote sensing technology. Multi temporal remote sensing image categorization can be used to derive richer spatiotemporal traits [17]. Indicatively, machine learning systems can use large volumes of satellite data to detect deforestation, monitor land use change, and monitor animal behaviour, thereby greatly accelerating and enhancing the precision of data classification over human efforts [18,19] [(**Table 1**) 5,9,10,20,21]. [Table 1: AI Techniques and their key environmental applications]

Deforestation and land use Monitoring: Deep learning AI-enabled applications such as Global Forest Watch use satellite images to identify deforestation in near real-time through the use of deep learning models. Such instruments give conservationists and policymakers the most up to date information enabling them to take timely actions to curb environmental destruction [18,19].

Environmental trends and behavioural Analysis: AI algorithms will be able to track animal behavioural changes that can tell about environmental changes, mating behaviours, or alterations in migratory patterns. This is necessary in learning the wider effects of climate change and habitat loss on the different species.

AI of all-inclusive Surveillance:

AI plus the IoT technology provide an opportunity to use a holistic approach to monitoring. Smart sensors placed in different settings are used to gather information regarding pollutants, soil moisture and temperature, which are processed by AI algorithms to analyze the data.

Real Time Environmental Monitoring: Integration of AI in environmental monitoring has worked especially well in the national parks and protected areas where AI-controlled cameras and drones will be able to notice any form of poaching and send alerts to the rangers in real-time [15]. These systems increase the effectiveness of conservation campaigns and the protection of the endangered species is improved because the system will react faster to the possible threat [14,22].

Data Analysis and Modeling

Analysis and modeling of data are essential parts of environmental science, especially when applied in AI and machine learning (ML).

Predictive Analytics in Environmental Science: Predictive analytics is a field within environmental science that involves predicting the future occurrence of events associated with the environment. Predictive analytics involve predicting the future of environmental-related events.

Key Application: Advanced forecasting models can be used to forecast the probability of extreme weather, evaluate the risk of drought, and more effectively manage resources under the influence of new conditions in the environment. Furthermore, machine learning algorithms, random forest and deep learning models [Convolutional Neural Networks (CNNs)] are used to process and analyze intricate ecological data [23,24].

Forecast models: This approach can be useful with such scenarios as predicting the frequency of flood occurrences or estimating the level of pollution. These models are useful in that, by using past numerical data, they give organizations the vision to get ready to the environmental challenges [25].

Advanced Techniques: More advanced data analysis is done by making use of advanced machine learning methods. Ensemble learning techniques and Long Short-Term Memory (LSTM) networks have been shown to be quite useful in increasing prediction accuracy through combining the effectiveness of more than one model, thus reducing the error and bias of an individual model [23,26].

Consevation Efforts: AI is becoming acknowledged as a game changer in conservation activities, as it assists in dealing with the crisis of biodiversity that is on the verge of becoming a worldwide issue and improving the management of ecosystems. The number of AI applications in conservation has also increased, and conservationists use them to track wildlife, restore habitats, and predict environmental changes successfully [27].

AI in Wildlife Monitoring: The implementation of automated camera traps and drone technologies has transformed wildlife monitoring because of the use of AI technologies to improve these tools. These technology tools apply advanced image recognition algorithms to automatically locate and track animals in their respective natural habitats, allowing to monitor animal populations and behaviours in real-time [28] [**Fig. 1**]. [Fig. 1: Schematic diagram showing application of AI technologies in Environmental research]

Habitat Restoration: AI is also useful in habitats restoration. Ecological data can be analyzed by algorithms that determine degraded areas that can be restored and thus prioritize areas in need of restoration [29].

Climate Change Mitigation

AI is also being seen as a possible solution to climate change through improved monitoring, predicting environmental changes, and optimizing resource management.

Green House Gas Emissions monitoring: Through infrared and multi-spectral measurements, these systems detect carbon dioxide (CO_2), methane (CH_4) and other air pollutants in the atmosphere and give real-time information on the quality of the air to policymakers [14].

Increasing Renewable Energy efficiency and decrease energy consumption : AI can optimize solar panel performance based on weather conditions and the state of the panel, which increases the amount of energy collected and anticipates maintenance. AI model may decrease energy consumption [2].

Reduction and Recycling Wastes: AI will help to reduce waste and boost recycling rates, which will promote a circular economy. The example of Carbon Bright, a climate tech startup, can be seen in the fact that it uses AI to perform product lifecycle analysis, which provides immediate evaluations of the environmental impact of consumer goods. Their platform helps track down the hotspots of the emissions across the supply chain, allowing the brands and retailers to switch to a more sustainable product with ease [23,30].

Environmental Monitoring: Smoke plumes and thermal variations can be detected in real time by AI algorithms to detect wildfires and response can be taken in a timely manner. Besides, AI is able to track water body changes, which judge the course and the level of rivers and lakes, which is crucial to urban planning and resources conservation [18,23].

Environmental Risk Assessment

Environmental risk assessment is the consideration of the possible negative impacts of environmental risks such as pollution and natural disasters on human health and the ecosystem. AI and ML are changing this sphere, as they allow making more accurate predictions and effective reactions to environmental threats.

Predictive Analytics for Natural Disaster: AI models can be important when it comes to predicting natural disasters through the analysis of big data through sensors, satellites and past occurrences. As an illustration, ML algorithms have the ability to analyze the weather patterns, the extent of soil moisture, and the conditions in the air to predict occurrences like floods, drought, and wild-fires. AI is able to process different parameters in order to forecast the magnitude and the effect of the catastrophe, which is vital in reducing the loss of life and property [31].

Pollution Monitoring and Control: There is also the use of AI technologies in tracking the quality of air and water hence determining the risks of pollution [18,32]. The AI-driven systems monitor the pollutants, including carbon dioxide (CO_2) and methane (CH_4), released by industrial processes and transport through real-time measurements of the environmental sensors [33]. These systems allow governments and organizations to enforce policy and devise a plan to reduce the risk to the environment by giving information on the level of pollution [34]. As an example, AI has been applied to predict the presence of smog in cities to take proactive action to counteract the decline of air quality [35].

Ecosystem and Biodiversity Conservation: Regarding the biodiversity conservation area, AI aids in risk assessment by tracking populations of the species and identifying habitat changes. Machine learning algorithms can recognize threatened species and estimate their susceptibility to anthropogenic factors and conserve them in the best way [15].

Challenges and Limitations: Although the concept of AI brings a lot of opportunities to the development of environmental sustainability, a variety of challenges and limitations will have to be mitigated to guarantee the successful and ethical use of AI. These are the problems of data-related concerns and ethical ones, and they can greatly affect the potential advantages of AI technologies in environmental science [(**Table 2)** 2,10,20,21,34,36,37]. [Table 2: Challenges in AI Environmental Research and mitigation strategies]

Data Limitations: Quality and availability of data is one of the main challenges of AI in terms of application to the environment. The existence of AI systems depends on big datasets to operate, therefore, the lack of data, including its quantity and quality, may negatively affect the progress. As an example, the validation of data used in species identification through crowd sourced images is often problematic, as it may lack representative coverage and reliable metadata [29, 34].

Evaluation of Environmental Impact of Ai

Finally, with the constantly growing AI, it is very important to evaluate the effect of AI on the environment [14]. Training big AI models may be expensive and add to carbon emissions. The current research should be extended to explore ways to minimize the carbon footprint that must be associated with AI development and implementation, including the use of cleaner energy and efficient optimization of algorithms [38].

Future Trends: The future of AI in the field of environmental science is marked with a number of emerging trends and developments that are set to increase its potential and efficacy in solving environmental issues.

Integration with IoT: The convergence of AI and IoT devices is one of the major trends [39]. This integration brings more in-depth and real time monitoring systems of the environment and causes decentralized and autonomous networks to improve the data collection and analysis potentials [23]. The resulting integration provides on-going monitoring of ecosystems that is less disruptive to delicate ecosystems as well as enriches our knowledge on the processes involved in the environment [40].

AI-based Decision Support systems: Another area that AI is opening the door to is the advancement of more complex decision support systems that put policymakers and environmental managers in control [41]. This development can help organizations to adopt strategic and sustainable climate and environmental policies in a better way [42].

Improving Predictive Abilities: With a better understanding of historical shifts in land use, agricultural practices, and water management, AI can be beneficial in identifying early signs of significant and minor transitions that have the potential to cause major ecological shifts [18].

Encouraging Stakeholder Collaboration : Involving the large group of stakeholders such as local populations, the government, and the private institutions, will not only reduce the conflict but will also improve the process of making decisions concerning the conservation of nature [22].

Developing Circular Economy : The implementation of AI technologies can also be one of the key contributors to a circular economy. The research directions in the future should be an AI usage that meets the challenges of the environment by means of a more efficient waste management system and resource recovery measures. As an example, AI can be used to discover and streamline recycling operations, thereby supporting the sustainability objectives and minimizing the environmental impact of different industries [32,43].

Sustainability and Ethical Contemplation

There is a need to make sure that AI solutions are not perpetrating any biases and should be built sustainably [23 UNESCO, 2023]. This entails reducing the negative environmental impact of AI systems, including energy consumption and electronic waste [34,44]. The need to use energy-efficient algorithms and encourage the use of the circular economy in AI development is critical in supporting the sustainability agenda [38,43,45].

Improved Climate Change Modeling and Projections: New technology of AI-powered simulation and modeling technologies will enhance the precision and finesse of climate forecasting and ecological evaluation [23]. The fact that the concentration of CO_2 in the air is alarming, and it is more than ever, makes the necessity of using accurate modeling tools more urgent [46].

Policy and Decision-Making Influence

With more advanced capabilities in analysis and real-time data analysis, AI applications have started to have a higher effect on environmental policy and decision-making processes, which provides a more productive approach to addressing complex environmental problems [47]. A multimodal CNN model is used in South Korea to predict the probability of wildfires. The model involves human, topographic and climatic variables. A deep learning model was based on a multimodal convolutional neural network. They may be used in such fields as ecological forecasting in the context of land use and land cover change, urban climate and air quality analysis, hydrologic and geomorphic hazards assessments [48]. Through the application of advanced algorithms, AI can be used to derive meaningful insights and track the trends that human analysts may not capture in time thereby enabling timely interventions in managing the environment [49].

CONCLUSION

The incorporation of AI in environmental studies has occurred at an accelerated pace over the last few years with both notable advancements and new challenge. Considering the interdisciplinary landscape surveyed in this review, it is noteworthy that AI has gone beyond the position of a supplementary analytical resource - it has become a key driver of the future of environmental science and sustainability. Recent studies point at a sustainability paradox. AI can not only improve environmental decision-making, but it also brings new environmental strains, unless models

are designed to be environmentally responsible. To reduce the effects of these issues, it is necessary to implement the principles of Green AI in the form of energy-efficient designs, the use of renewable energies, explainable models, and the governance of the lifecycle. AI in environmental research represents an extremely promising and yet highly responsible way to go. AI increases our ability to perceive, anticipate, and react to change in the environment, helping professionals, policy makers and stakeholders to address pressing global issues with accurate data. Its implementation promotes better environmental resilience, more efficient resource management and closer adherence to the global sustainability goals. A deliberate effort towards sustainable innovation, one which considers ecological boundaries without exploiting computational ingenuity, will be a fundamental necessity as researchers and practitioners continue to progress in this direction going forward, and thus, to make AI not just a technological angle of attack, but a driver of planetary health.

Conflict of Interest

ABSTRACT

Hypothyroidism is a common endocrine disorder with significant metabolic and cardiovascular consequences, most often caused by autoimmune thyroiditis in iodine-sufficient regions. Anti-thyroid peroxidase (anti-TPO) antibodies are highly sensitive markers of thyroid autoimmunity and may also reflect systemic inflammation. In this case control study 200 individuals were evaluated including 120 patients with hypothyroidism and 80 age and sex matched euthyroid controls. Serum levels of T3, T4, TSH, anti-TPO antibodies, high-sensitivity C-reactive protein (hsCRP) and erythrocyte sedimentation rate (ESR) were measured and correlations were analyzed using Pearson's Correlation coefficient. Results showed that hypothyroid patients had significantly elevated TSH and reduced T4 alongside markedly higher anti-TPO titers compared to controls. Inflammatory markers were also raised with hsCRP and ESR levels significantly higher in cases and a strong positive correlation was observed between anti-TPO and ESR while associations with hsCRP and TSH were weak and non-significant. These findings demonstrate

that elevated anti-TPO antibodies are strongly associated with thyroid dysfunction and systemic inflammation, reinforcing their diagnostic and prognostic value. Integrating anti-TPO measurement with inflammatory markers In hypothyroid patientsmay enhance risk stratification, guide therapeutic decisions and help identify patients at increased risk of multisystem complications. Longitudinal studies are warranted to establish their predictive utility in disease progression and comorbid autoimmune disorders.

Keywords: Anti - thyroid peroxidase antibodies (Anti - TPO), Autoimmune thyroiditis, Hypothyroidism, Autoimmune thyroid disease.

INTRODUCTION

Hypothyroidism is one of the most prevalent endocrine disorders worldwide, with significant effects on metabolism, cardiovascular function and quality of life(1,2). In iodine sufficient regions, autoimmune thyroiditis particularly Hashimoto's thyroiditis remains the leading cause(3,4,5). The condition is characterized by progressive thyroid tissue destruction mediated by auto-reactive lymphocytes and the presence of circulating thyroid auto-antibodies(6,7). Among these autoantibodies anti-thyroid peroxidase (anti-TPO) antibodies are recognized as the most sensitive and specific markers of autoimmune thyroid disease(8,9,10,11). Thyroid peroxidase is a key enzyme in thyroid hormone biosynthesis and its targeting by anti- TPO antibodies reflects ongoing immune mediated thyroid damage(12,13). Elevated titers of anti- TPO antibodies are frequently observed not only in patients with overt hypothyroidism but also in euthyroid individuals at risk of developing thyroid dysfunction Suggesting or pointing their diagnostic and prognostic utility(14,15,16,17,18). Beyond their role in thyroid specific autoimmunity anti-TPO antibodies have been linked to systemic immune activation(19,20,21,22). Several studies suggest associations between antibody titers and inflammatory markers such as erythrocyte sedimentation rate (ESR) and high sensitivity C- reactive protein (hsCRP)(23,24,25,26). ESR reflects the overall inflammatory burden while hsCRP serves as a sensitive marker of low-grade chronic inflammation and has been marked in cardiovascular risk among hypothyroid patients(27–29).

Elevated levels of these markers in autoimmune thyroid disease highlight the interactionbetween thyroid autoimmunity and systemic inflammation(30–32). The clinical implications of this association are considerable. Chronic inflammation in hypothyroidism has been linked to dyslipidemia, atherosclerosis and increased cardiovascular risk(33–37). Patients with high anti-TPO titers may therefore represent a subset at increased risk of inflammatory complications, making antibody measurement significant not only for diagnosis but also for well risk categorization (28,31,38,39).Regardless of the acknowledged importance of anti-TPO antibodiesambiguous data exist on their quantitative relationship with thyroid hormone parameters (T3, T4, TSH) and inflammatory indicators in well-defined case control settings. comprehending these associations may offer valuable perception into the immuno-pathogenesis of hypothyroidism, improve risk classification and guide all inclusive management plans that address both endocrine dysfunction and systemic inflammatory activity. The present study was therefore designed to compare anti-TPO antibody levels in patients with subclinical hypothyroidism and euthyroid controls and to evaluate their relationship with thyroid hormone parameters and inflammatory markers (hsCRP, ESR). By exploring these associations, we aim to elucidate thus the role of anti-TPO antibodies as biomarkers of both thyroid-specific autoimmunity and systemic inflammation thereby augmenting their clinical relevance in the diagnosis, prognosis and management of hypothyroidism.

MATERIALS AND METHODS

This case control study was conducted on a total of 200 individuals comprising 120 patients diagnosed withhypothyroidism and 80 age and sexmatched healthy controls. Participants were recruited from the outpatient clinics of the Department of Medicine.

The inclusion criteria for the SCH group were:

- Age between 18 and 50 years.
- Newly diagnosed cases ofclinical and subclinicalhypothyroidism Patient defined as elevated serum thyroid-stimulating hormone (TSH) levels with normal free triiodothyronine (FT3) and free thyroxine (FT4) concentrations.
- No prior history of thyroid hormone replacement therapy or immuno-suppressive treatment.

Exclusion criteria included:

- Hyperthyroidism.
- Pregnancy or lactation.
- Presence of autoimmune diseases other than thyroid autoimmunity.
- Chronic inflammatory disorders, recent infections or any systemic illness known to influence thyroid function or inflammatory markers.
- Use of medications that could interfere with thyroid function or immune response.

Healthy controls:-Healthy Controls were selected from the same demographic population matched for age and sex and confirmed to have normal thyroid function tests and no history of autoimmune or chronic inflammatory disease.

Ethical Considerations

The study protocol was reviewed and approved by the Institutional Ethics Committee (Ref. No. SMC/UECM/2024/914). Written informed consent was obtained from all participants prior to enrollment.

Sample Collection and Processing

Venous blood samples (5 mL) were collected from each participant under strict aseptic precautions using sterile vacutainers. Samples were allowed to clot at room temperature and subsequently centrifuged at 3000 revolutions per minute (rpm) for 10 minutes. The separated serum was aliquoted into sterile cryovials and stored at –20 °C until further biochemical and immunological analysis.

Laboratory Investigations

Statistical Analysis

Correlation analysis performed using Pearson's correlation coefficient to assess relationships between:

- Anti-TPO and TSH
- Anti-TPO and hsCRP
- Anti-TPO and ESR

Statistical significance was defined as $p < 0.05$.

RESULTS

Comparative analysis between the case group (n = 120) and control group (n = 80) revealed significant differences across multiple biochemical and immunological markers. Serum T3 levels were comparable between groups (Case: 1.59 ± 0.61 ng/mL; Control: 1.65 ± 0.80 ng/mL; P = 0.549) indicating no statistically significant difference. However, T4 levels were markedly reduced in cases (81.85 ± 30.34 μg/dL) compared to controls (109.52 ± 24.61 μg/dL), with a highly significant difference (P < 0.0001). TSH levels were substantially elevated in the case group (43.34 ± 35.07

μIU/mL) relative to controls (2.90 ± 1.20 μIU/mL), also reaching statistical significance (P< 0.0001) consistent with a hypothyroid profile. Autoimmune markers showed pronounced elevation in cases. Anti-thyroid peroxidase (Anti-TPO) antibody were significantly higher in the case group (94.03 ± 21.23 IU/mL) than in controls (25.44 ± 11.56 IU/mL; P < 0.0001).The Inflammatory markers were also significantly raised in the case group. High-sensitivity C-reactive protein (hsCRP) levels were elevated (14.31 ± 3.49 mg/L) compared to controls (2.35 ± 1.01 mg/L; P < 0.0001) and erythrocyte sedimentation rate (ESR) was higher in cases (27.98 ± 5.55 mm/hr) than controls (17.4 ± 1.39 mm/hr; P < 0.0001) indicating a heightened systemic inflammatory response. In the case group (n = 120) anti-thyroid peroxidase (Anti-TPO) antibody levels were elevated with a mean of 94.03 ± 21.23 IU/mL and a median of 93.5 IU/mL, indicating autoimmune thyroid involvement. Erythrocyte sedimentation rate (ESR) values were also elevated with a mean of 27.98 ± 5.55 mm/hr and a median of 30 mm/hr, reflecting a heightened systemic inflammatory state. Pearson correlation analysis revealed a strong positive association between Anti-TPO and ESR levels (R = 0.817) which was statistically significant (P = 0.000).

DISCUSSION

Our study evaluated the association between thyroid dysfunction, autoimmune activity, and systemic inflammation in hypothyroid patients. The findings provide significant alterations in thyroid hormones, autoantibodies and general inflammatory markers in the cases in comparison to controls. Consistent with previous literature, autoimmune thyroiditis particularly Hashimoto's thyroid it is remains the leading cause of hypothyroidism in iodine-sufficient populations with anti-TPO antibodies serving as the most sensitive and specific marker of thyroid autoimmunity(3,5,6,8,12,26). Hypothyroid patients exhibited marked elevation of TSH levels and anti-TPO antibodies and reduced T4 concentrations consistent with impaired thyroid function(7,13,19,26. Significantly higher titers of anti-TPO antibodies in cases insinuate their diagnostic utility and strengthen their role in screening individuals at risk of progressive thyroid failure (11,15,25,38). In terms of thyroid hormone). Notably, T3 levels did not differ significantly between groups and may reflect compensatory mechanisms or the relatively early stage of thyroid dysfunction in subclinical hypothyroidism(21,25,26). The strong elevation of TSH alongside rise in anti-TPO highlights the classical biochemical profile of hypothyroidism and supports the clinical relevance of incorporating antibody testing for all-inclusiveanalysis15,17,18).

Our study further explored systemic inflammation in hypothyroidism. Both hs-CRP and ESR were significantly elevated in hypothyroid patients implying that thyroid autoimmunity may also contributes to systemic inflammation(1,2,4, 23,19,20,27,28).However, the correlation between anti-TPO and hsCRP was weak and not statistically significant(2,20), the strong positive correlation between anti-TPO and ESR indicates that raised antibody titers may reflect the overall inflammatory burden(3,4,23). This finding is particularly relevant given the established connection between chronic inflammation and cardiovascular risk (16,29–32,40), suggesting that hypothyroid patients with high anti-TPO titers may represent a subgroup at increased risk of inflammation related complications (10,14,31,32). The results highlight the dual role of anti-TPO antibodies not only as markers of thyroid-specific autoimmunity but also as potential indicators of systemic inflammation (8,10,20,24,25,26,28,30,38). This association point out the significance of anti TPO particularly in predicting disease progression and identifying those at risk of inflammatory comorbidities (9,12,10,26,28). Clinically these findings support the integration of anti-TPO testing with inflammatory markers such as ESR and hs-CRP to provide a more holistic assessment of disease severity (1,2,3,4,23,31).

The correlation analysis demonstrated a weak and statistically non-significant negative correlation between TSH and anti-TPO levels. This suggests that although both markers are elevated in hypothyroidism, they may reflect different aspects of disease pathology. Similarly, the very weak and non-significant negative correlation between anti-TPO and hsCRP suggest that autoimmune thyroid activity may not directly correlate with acute phase inflammatory responses measured by hsCRP. This could be due to the chronic and organ specific nature of autoimmune thyroiditis, which may not always produce a proportional systemic inflammatory response detectable by hsCRP. In contrast, a strong

and statistically significant positive correlation was found between Anti-TPO and ESR. This observation suggests that ESR, being a marker of sustained inflammatory processes, may better reflect the chronic immune activation seen in autoimmune thyroid disorders compared to hsCRP. Overall, the results indicate that hypothyroidism, particularly of autoimmune origin, is associated with a heightened inflammatory state. However, the relationship between autoimmune markers and inflammatory parameters appears to vary depending on the specific marker evaluated. Certain limitations must be acknowledged. Due to its cross-sectional design, it is unable to determine the causal links between antibody increase and progression of disease. Sample size, although sufficient for statistical analysis may not fully represent the range of autoimmune illness. Longitudinal studies in future may better ascertain whether increased anti-TPO levels directly contribute to systemic inflammation or predictive of hypothyroidism advancement or emergence of related autoimmune diseases. Future research should also explore the genetic analysis and cytokine profiling to get more profound understanding of immune pathogenesis of hypothyroidism.

CONCLUSION

The study highlights the complex interaction between thyroid function, autoimmunity and inflammation. While anti-TPO strongly reflect autoimmune involvement, their correlation with inflammatory markers is variable, with ESR showing a stronger association than hsCRP. These findings reinforce the diagnostic and prognostic value of anti-TPO antibodies not only as markers of thyroid-specific autoimmunity but also as potential indicators of systemic inflammatory activity. Integrating anti-TPO measurement with inflammatory indicators may enhance risk assessment and guide more comprehensive therapeutic approaches that address both thyroid dysfunction and systemic inflammation. Future long-term studies are warranted to investigate the predictive utility of anti-TPO antibodies in disease progression and to clarify their role in identifying patients at risk for comorbid inflammatory or autoimmune disorders.

ACKNOWLEDGEMENT

The authors sincerely acknowledge the support and guidance received from the Departments of Biochemistry, Medicine at CSSH Hospital, Subharti Medical College, Swami Vivekanand Subharti University, Meerut, Uttar Pradesh, India, where this study was conducted. We extend our gratitude to the faculty and technical staff for their assistance in laboratory investigations and data collection. We are deeply thankful to the Institutional Ethics Committee for reviewing and approving the study protocol, ensuring that the research was conducted in accordance with ethical standards. Our heartfelt appreciation goes to all the participants who volunteered for this study and provided valuable samples and clinical information. Without their cooperation, this research would not have been possible. Finally, we acknowledge the contributions of colleagues and peers who provided constructive feedback during the preparation of the manuscript.

Conflict of interest:- No Conflict of interest to disclose.
Funding:- Nil.

ABSTRACT

Antimicrobial proteins play a crucial role in innate immunity and represent promising alternatives to conventional antibiotics. The present study focuses on the purification, characterization, sequence analysis, and structural prediction of antimicrobial proteins isolated from *Scylla* species. Antimicrobial proteins obtained from granular haemocyte extracts were purified using ion-exchange chromatography and analysed through SDS-PAGE. Further identification and characterization of proteins were carried out using tandem mass spectrometry (MS/MS) and bioinformatics tools including BLAST, ClustalW, PEP-FOLD3, and MODELLER. The purified fractions exhibited significant antimicrobial activity and distinct protein bands were observed during electrophoretic analysis. Sequence alignment and phylogenetic studies revealed evolutionary relationships among the identified proteins, while homology modelling provided insights into their three-dimensional structures and active sites. The findings suggest that antimicrobial proteins from *Scylla* species possess potential therapeutic significance and may contribute to the development of novel antimicrobial agents.

Keywords: Antimicrobial proteins, *Scylla serrata*, *Scylla olivacea*, SDS-PAGE, MS/MS analysis, Homology modelling, Bioinformatics

INTRODUCTION

The rapid emergence of multidrug-resistant microorganisms has become a major global health concern, creating an urgent need for the discovery of novel antimicrobial compounds from natural sources. Conventional antibiotics are gradually losing effectiveness due to the widespread development of resistance among pathogenic bacteria, fungi, and viruses. In this context, antimicrobial proteins and peptides (AMPs) derived from marine organisms have attracted considerable scientific attention because of their broad-spectrum antimicrobial properties, rapid mode of action, and low tendency to induce resistance (Hancock and Sahl, 2006; Yeaman and Yount, 2003). Marine invertebrates represent a rich source of biologically active compounds owing to their continuous exposure to diverse and pathogen-rich aquatic environments. Among marine organisms, crustaceans possess highly developed innate immune systems that rely primarily on cellular and humoral defence mechanisms. Unlike vertebrates, crustaceans lack adaptive immunity and depend heavily on antimicrobial proteins and peptides synthesized by haemocytes to combat microbial invasion (Smith et al., 2008). Crabs belonging to the genus *Scylla*, including *Scylla serrata* and *Scylla olivacea*, are economically and ecologically important marine crustaceans known for their robust immune responses and production of potent antimicrobial molecules.

Antimicrobial proteins isolated from crustaceans exhibit significant activity against Gram-positive and Gram-negative bacteria, fungi, and certain viruses. These proteins often contain cationic and hydrophobic amino acid residues that enable interaction with microbial membranes, ultimately causing membrane disruption and cell death (Matsuzaki, 1999). Due to these unique properties, crustacean-derived antimicrobial proteins are increasingly being explored as promising candidates for pharmaceutical and therapeutic applications. Advances in proteomics and molecular biology have greatly improved the identification and characterization of antimicrobial proteins. Techniques such as ion-exchange chromatography and SDS-PAGE are commonly used for protein purification and molecular weight determination (Laemmli, 1970). Furthermore, mass spectrometry-based approaches including tandem mass spectrometry (MS/MS) provide accurate peptide sequencing and protein identification (Tsugita et al., 2000). Bioinformatics tools such as BLAST, CLUSTALW, and MEGA facilitate sequence comparison and phylogenetic analysis, while computational modelling platforms like PEP-FOLD3 and MODELLER enable prediction of peptide conformation and three-dimensional protein structures (Altshul et al., 1990; Thompson et al., 1994; Lamiable et al., 2016)

Structural characterization of antimicrobial proteins is essential for understanding their mechanism of action, stability, and functional domains. Homology modelling and structural validation programs such as PROCHECK, VERIFY3D, and ERRAT provide reliable insights into stereo chemical quality and protein architecture (Laskowski et al., 1993; Eisenberg et al., 1997). These computational approaches significantly contribute to the development of peptide-based therapeutics and drug design strategies. Although several antimicrobial proteins have been identified from marine organisms, studies focusing on the purification and structural characterization of antimicrobial proteins from *Scylla* species remain limited. Therefore, the present study was undertaken to purify and characterize antimicrobial proteins from *Scylla serrata* and *Scylla olivacea* using chromatographic, electrophoretic, proteomic, and bioinformatics approaches. The study further aimed to analyse the sequence homology, phylogenetic relationships, and three-dimensional structures of the identified proteins in order to understand their functional and evolutionary significance. The increasing emergence of multidrug-resistant microorganisms has intensified the search for novel antimicrobial compounds from natural sources. Marine organisms, especially crustaceans, are considered valuable reservoirs of bioactive molecules due to their unique immune defence mechanisms. Crabs belonging to the genus *Scylla* possess potent innate immune systems that produce antimicrobial proteins capable of combating pathogenic microorganisms.

Antimicrobial proteins and peptides are essential components of the innate immune response in invertebrates. These molecules exhibit broad-spectrum antimicrobial activity against bacteria, fungi, and viruses. Due to their effectiveness and low probability of resistance development, antimicrobial proteins are gaining significant attention

in pharmaceutical and biomedical research. Advances in proteomics and bioinformatics have enabled the identification and structural characterization of antimicrobial proteins. Techniques such as ion-exchange chromatography, SDS-PAGE, and mass spectrometry provide detailed information regarding protein purification and molecular characterization. Furthermore, computational tools such as BLAST, ClustalW, and MODELLER facilitate sequence comparison, phylogenetic analysis, and three-dimensional structure prediction. The present study was designed to purify and characterize antimicrobial proteins from *Scylla* species and to analyse their structural and evolutionary properties using bioinformatics approaches.

MATERIALS AND METHODS

Purification of Antimicrobial Proteins

The samples exhibiting significant antimicrobial activity were purified using ion-exchange chromatography according to the method described by Zasloff (1987). The dialyzed extract of granular hemocytes (5 mL) was loaded onto a glass column (36 × 2.8 cm) packed with carboxymethyl cellulose equilibrated with 0.2 M sodium acetate buffer (pH 4.0). Unbound proteins were washed with sodium acetate buffer until the absorbance reached baseline levels. Bound proteins were subsequently eluted using 0.2 M ammonium acetate buffer (pH 5.2). Fractions of 2 mL each were collected and monitored spectrophotometrically at 280 nm using a UV-160A Shimadzu spectrophotometer.

SDS/Polyacrylamide Gel Electrophoresis (SDS-PAGE)

One-dimensional SDS-PAGE was performed according to the method of Laemmli (1970) using a Bio-Rad vertical slab gel electrophoresis system. The stacking gel contained 4% acrylamide while the resolving gel consisted of 15% acrylamide. Protein fractions were diluted with sample loading buffer containing 20% glycerol, 1% SDS, 0.125 M Tris-HCl, 2% β-mercaptoethanol, and 0.5% bromophenol blue. The samples were heated at 100°C for 5 min and centrifuged at 10,000 ×g for 5 min. The supernatant was loaded into the wells and subjected to electrophoresis.

Molecular weight markers obtained from GeNei (Bangalore) were used for calibration. The gels were stained using silver nitrate for visualization of protein bands.

MS/MS Analysis and Data Processing

MS/MS analysis was performed using Coomassie-stained protein spots corresponding to purified antimicrobial proteins. Gel pieces were rehydrated in 50 mM ammonium bicarbonate, diced into approximately 1 mm3 cubes, destained, and digested using trypsin (100 ng/sample). The digested samples were diluted with 3% acetonitrile and 0.1% formic acid. Approximately 30% of each sample was chromatographed using an Agilent Protein ID Chip column assembly connected to an HCT ultra 3D ion-trap mass spectrometer. The column was equilibrated with 4% acetonitrile and 0.1% formic acid at a flow rate of 0.5 μL/min. Samples were eluted with an acetonitrile gradient ranging from 4–31% over 32 min. Ionizable species within the range of 300–1300 m/z were trapped and fragmented through collision-induced dissociation. MS and MS/MS spectra were analysed using Bruker Daltonik Data Analysis software for peak detection and peptide identification.

Sequence Analysis

The amino acid sequences obtained from MS/MS analysis were compared against database sequences using the NCBI BLAST server(Fig 1). MASCOT MS/MS ion search analysis was performed with the following parameters:

- Enzyme: Trypsin
- Allowed missed cleavage: One
- Fixed modification: Carbamidomethylation
- Variable modifications: Oxidation (HW) and oxidation (M)
- Peptide mass tolerance: 0.5 Da
- Fragment mass tolerance: 0.5 Da
- Charge states: +1, +2, +3
- Instrument type: ESI-TRAP

Proteins with scores greater than 50 for the NCBI database and greater than 45 for the Swiss-Prot database were considered statistically significant ($p < 0.05$).

De Novo Peptide Structure Prediction

Active peptides identified from the Mascot server were subjected to de novo peptide structure prediction using the PEP-FOLD3 server (Fig 2) . This server predicts peptide structures ranging from 5 to 50 amino acids using a de novo modelling approach. The predicted structures provided information regarding peptide folding, stability, and potential functional conformations.

Multiple Sequence Alignment and Phylogenetic Analysis

The identified antimicrobial protein sequences were aligned in FASTA format using ClustalW implemented in MEGA software. Phylogenetic relationships among the sequences were analysed using the neighbour-joining method. Similarities and evolutionary relationships among the proteins were inferred from the generated phylograms.

Homology Model Generation of Sequenced Proteins

Template Search and Sequence Alignment

The amino acid sequences obtained from male and female crabs of *Scylla serrata* and *Scylla olivacea* were subjected to BLASTP analysis against the Protein Data Bank to identify suitable templates for homology modelling. Templates were selected based on maximum sequence identity, high scores, and low e-values. Sequence alignment between target and template proteins was performed using CLUSTALW.

Three-Dimensional Structure Generation

Three-dimensional structures of antimicrobial proteins were generated using MODELLER software. The software employed probability density functions as spatial restraints to generate reliable protein models.

Among the generated models, the best model was selected based on:

- PROCHECK G-score
- VERIFY3D validation
- ERRAT quality assessment
- Lowest DOPE energy score

The finalized model was subjected to active site identification and molecular interaction analysis.

MODELLER Workspace Files

Search File

The search file contained the target sequence specified as qseq1. The command “mod9v1 search.py” was used to identify suitable template sequences.

Alignment File

The alignment file contained aligned target and template sequences in FASTA format (Fig 3).The command “mod9v1 malign.py” was used to verify the alignment and template structure compatibility.

Template Selection File

Potential template sequences showing significant similarity and E-values equal to zero were analysed for appropriate template selection.

Model Building File

The get-model file specified the target sequence and template structure. MODELLER automatically generated five structural models using the auto model class.

Model Evaluation File

Generated models were evaluated based on objective function values and DOPE scores to identify the most stable and energetically favourable protein structure.

RESULTS AND DISCUSSION

Purification of Antimicrobial Proteins

Ion-exchange chromatography successfully separated antimicrobial protein fractions from granular haemocyte extracts. Protein elution profiles showed distinct absorbance peaks at 280 nm, indicating successful purification of protein components. The purified fractions exhibited enhanced antimicrobial activity compared to crude extracts, suggesting the enrichment of active antimicrobial proteins.

SDS-PAGE Analysis

SDS-PAGE analysis revealed distinct protein bands corresponding to antimicrobial proteins of varying molecular weights. The presence of clearly resolved bands indicated the purity and integrity of the isolated proteins (Fig 4) . Silver staining enhanced the visualization of low-abundance protein fractions.

Mass Spectrometry and Sequence Analysis: MS/MS analysis enabled the identification of peptide sequences associated with antimicrobial activity. Database searches using BLAST and MASCOT confirmed homology with known antimicrobial proteins reported in crustaceans and other marine organisms.

The identified proteins showed significant similarity scores, indicating the conserved nature of antimicrobial proteins among marine invertebrates.

De Novo Structure Prediction

The PEP-FOLD3 server successfully generated stable peptide conformations for the identified antimicrobial peptides (Table 1). Predicted structures demonstrated characteristic α-helical and β-sheet arrangements commonly associated with antimicrobial peptides.

Phylogenetic Analysis

Multiple sequence alignment and phylogenetic analysis demonstrated evolutionary conservation among antimicrobial proteins from *Scylla* species and related crustaceans. The phylogenetic tree indicated close relationships between proteins from *S. serrata* and *S. olivacea*.

Homology Modelling

Homology modelling produced reliable three-dimensional structures for the sequenced proteins. Validation through PROCHECK, VERIFY3D, and ERRAT confirmed the stereochemical quality and structural stability of the models.

The predicted structures provided valuable insights into the functional domains and active sites involved in antimicrobial activity.

DISCUSSION

The present study successfully demonstrated the purification, characterization, and structural analysis of antimicrobial proteins from *Scylla* species, emphasizing their potential role in innate immunity and biomedical applications. Marine crustaceans are constantly exposed to a wide range of pathogenic microorganisms in aquatic environments and therefore depend on innate immune defence molecules such as antimicrobial proteins and peptides for survival. The findings of this investigation are consistent with previous reports highlighting crustaceans as important reservoirs of bioactive antimicrobial compounds (Smith et al., 2008). Ion-exchange chromatography effectively purified antimicrobial protein fractions from granular haemocyte extracts. The appearance of distinct absorbance peaks at 280 nm confirmed successful protein separation based on ionic interactions. Similar purification procedures have been employed for isolation of antimicrobial proteins from marine organisms and have proven effective in enriching biologically active fractions (Tsugita et al., 2000). The enhanced antimicrobial activity observed in purified fractions compared with crude extracts indicates successful concentration of active antimicrobial proteins during the purification process.

SDS-PAGE analysis revealed distinct protein bands of varying molecular weights, suggesting the presence of multiple antimicrobial proteins within the haemocyte extracts. The clear resolution of protein bands after silver staining indicated good purity and integrity of the isolated proteins. Previous studies have also reported that crustacean antimicrobial systems contain several low molecular weight peptides that function synergistically in

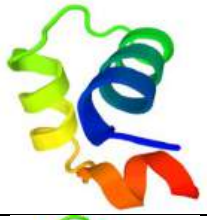
microbial defence (Laemmli, 1970). The observed electrophoretic diversity may therefore represent different antimicrobial proteins or peptide isoforms involved in immune responses. MS/MS analysis provided detailed peptide sequence information and enabled identification of proteins associated with antimicrobial activity. Database analysis using BLAST and MASCOT revealed significant homology between the identified proteins and previously reported antimicrobial proteins from marine invertebrates. The presence of conserved hydrophobic and positively charged amino acid residues is characteristic of antimicrobial peptides involved in microbial membrane interaction and disruption (Yeaman and Yount, 2003). Such conserved structural features strongly support the antimicrobial function of the isolated proteins. Sequence alignment studies performed using CLUSTALW demonstrated conserved amino acid regions among proteins isolated from *Scylla serrata* and *Scylla olivacea*. Conserved motifs identified in the present study may play important roles in maintaining antimicrobial activity and structural stability. Similar evolutionary conservation of antimicrobial proteins has been reported among crustaceans and other marine invertebrates, indicating that these proteins are subjected to strong evolutionary pressure due to their essential defensive functions (Thompson et al., 1994).

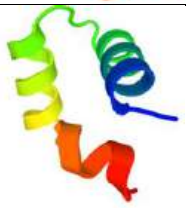
De novo peptide structure prediction using the PEP-FOLD3 server generated stable peptide conformations characterized by α-helices and β-sheet structures. These structural motifs are commonly observed in antimicrobial peptides and are known to facilitate insertion into microbial membranes leading to membrane permeabilization and cell lysis (Lamiable et al., 2016). The predicted structures therefore provide strong evidence supporting the membrane-active mechanism of the isolated antimicrobial proteins. Phylogenetic analysis revealed close evolutionary relationships among antimicrobial proteins from *Scylla* species and related crustaceans. The phylogenetic clustering observed in this study suggests that these proteins may have evolved from common ancestral immune proteins while preserving their antimicrobial functions. Such evolutionary conservation reflects the biological importance of antimicrobial proteins in crustacean defence systems (Koichiro et al., 2007). Homology modelling using MODELLER successfully generated reliable three-dimensional structures of the identified antimicrobial proteins. Validation using PROCHECK, VERIFY3D, ERRAT, and DOPE score analysis confirmed the stereochemical accuracy and structural stability of the predicted models (Laskowski et al., 1993; Eisenberg et al., 1997). Structural modelling also enabled identification of potential active sites and functional domains associated with antimicrobial activity. Comparative protein modelling has become an important strategy for understanding protein function and designing peptide-based therapeutics (Sali and Blundell, 1993).

The increasing prevalence of antibiotic-resistant pathogens has intensified the search for alternative antimicrobial agents from natural sources. Antimicrobial proteins from marine crustaceans possess several advantages including rapid microbial killing, broad-spectrum activity, and lower chances of resistance development compared with conventional antibiotics (Hancock and Sahl, 2006). Therefore, the antimicrobial proteins identified in the present study may serve as promising candidates for future pharmaceutical and therapeutic applications.Overall, the present investigation demonstrated that *Scylla* species are valuable sources of structurally conserved and biologically active antimicrobial proteins. The integration of chromatographic purification, proteomic analysis, sequence characterization, phylogenetic studies, and structural modelling provided comprehensive insights into the molecular properties of these proteins. Further studies involving recombinant expression, molecular docking, toxicity evaluation, and in vivo antimicrobial assays may facilitate the development of novel peptide-based antimicrobial drugs for combating multidrug-resistant pathogens.

CONCLUSION

The present study successfully purified and characterized antimicrobial proteins from *Scylla* species using chromatographic, electrophoretic, proteomic, and bioinformatics approaches. MS/MS analysis and sequence characterization confirmed the presence of potent antimicrobial proteins exhibiting conserved structural features. Bioinformatics analyses, including sequence alignment, phylogenetic studies, and homology modelling, provided significant insights into the evolutionary relationships and structural properties of these proteins. The generated





three-dimensional models may facilitate further studies on protein function, molecular interactions, and therapeutic applications. The findings of this investigation highlight the potential of marine crustaceans as promising sources of novel antimicrobial agents for biomedical and pharmaceutical applications.

ABSTRACT

Celastrus paniculatus Willd. is an important medicinal plant, belongs to Celstraceae family. Various plant parts like seeds, barks etc. of this plant are having great medicinal values. So, in nature this plant is overexploited for its various valuable plant parts. So, an alternative option for increasing number of plants in nature, an *in vitro* protocol has been established for large scale multiplication of *Celastrus paniculatus* Willd. through direct and indirect shoot regeneration to ensure replenishment of this important medicinal plant using various explants like leaf and nodal explants. In results of direct shoot regeneration, MS medium fortified with BAP (1.0 mgl^{-1}) + IAA (1.0 mgl^{-1}) was found to be most effective in formation of maximum shoots directly from nodal explants after 4 weeks whereas Leaf explants were used for indirect callus mediated shoot regeneration in MS medium fortified with BAP (1.0 mgl^{-1}) which was proved to be best for both callus formation and multiple shoot induction after 4 weeks. The directly and indirectly regenerated shoots were rooted well in MS medium containing NAA (2.0 mgl^{-1}) and were acclimatized with approx 60-70 percent survival rate. The genetic stability of the regenerated plants was further confirmed by using random amplified polymorphic DNA (RAPD) which found to be highly monomorphic and proved true-to-type. The significant results for regeneration are observed. Thus, an efficient protocol for rapid propagation of *C. paniculatus*is generated, which can be used for large scale multiplication of true-to-type plants and also unlock the new possibilities for its conservation.

Keywords: Callus, *Celastrus*, Malkanguni, RAPD, Shoot regeneration

INTRODUCTION

*Celastrus paniculatus*Willd. is a perennial woody climber commonly known as Black oil plant or Malkanguni belongs to Celastraceae. In traditional system of medicine, the seeds oil is used for memory enhancement and for treatment of neural disorders and leaves and bark of plant is utilized for treatment of rheumatism, dysentery and various skin ailments. Periodically various pharmacologically active phyto-compounds viz, paniculatine, celastrine, malkangunin, celastrol, Celapanigin, β-amyrin and β-sitosterol have been identified from the plant extracts of *C. paniculatus* [1-2]. This plant is mainly propagated by seeds, but low seed germination capacity and poor seed viability restrict its natural population. Secondly the seeds of this plant are highly used to extract oil from it subsequently, large-scale and uncontrolled harvesting of plant parts to satisfy rising need of the pharmaceutical industry adversely affected plant survival so, to cope up with this alarming situation, a rapid, reliable and genetically stable protocol is required which may be fulfilled by *in vitro* culture technique as it was reported successful in many medicinal plant species.

The aim of this study was to developed and established protocol for *in vitro* plant regeneration of *Celastrus paniculatus*Willd. Previously, some reports were available on *in vitro* propagation of *C. paniculatus* using different explants and approach of regeneration [3-7] and very few reports were there for genetic fidelity assessment [8-10], but proper protocol for *in vitro* multiplication is needed for conservation of this precious climber. Simultaneously, it is necessary to maintain the true-to-type nature of tissue culture raised plants, for that the genetic stability assessment of micropropagated plants is required to ensure the quality of the regenerated plants. RAPD technique has several advantages such as the ease and rapidity in analysis, relatively low cost, availability of a large number of primers and the requirement of a very small amount of DNA for analysis [11]. Some previous scientific literature revealed the genetic fidelity assessment through RAPD by Mathur *et al.,*[8], Phulwaria*et al.,*[9] and Senapati *et al.,*[10] on *in vitro* regenerated and mother plants but here in present work genetic fidelity assessment of *in vitro* raised plants with rapid and reliable protocol. Therefore, the present investigation was undertaken with these two objectives 1) to develop efficient and reproducible protocol for *in vitro* plant regeneration of *Celastrus paniculatus*Willd. through direct and indirect shoot regeneration and 2) *in vitro* raised plants were further evaluated for their genetic stability using RAPD markers.

MATERIAL AND METHODS

***In vitro* regeneration technique**

Selection and Collection of explants

Leaf and Nodal segments with auxiliary bud were selected as explants and were collected from the climber growing on hedges of local field of Kheralu (23°53′19″N 72°36′41″E), Dist. Mehsana, Gujarat. Leaf and Nodal segments were thoroughly washed under running tap water for 15-20 min to remove adhered dust particles and rinsed thrice with sterile distilled water, then after the explants were surface sterilized with 80% ethanol (v/v) for 1 min, immersed in 0.1% (w/v) mercuric chloride under the sterile conditions for 10 min and rinsed thrice with sterile distilled water.

Media composition and culture conditions

MS medium [12] supplemented with 3% (w/v) sucrose and 0.8% (w/v) agar (Himedia, Mumbai, India) was used during the study. The medium was adjusted to pH 5.8 using 1 N NaOH and sterilized by autoclaving at 121°C and 1.06 kg cm^{-2} pressure for 20 min. Cultures were incubated at 24 ± 2°C under 16:8 h light:dark photoperiod maintained through cool white fluorescent tubes with 3000 lux light intensity (Philips, India).

Direct shoot regeneration

The sterilized nodal segments were inoculated on Murashige and Skoog (1962) medium with different concentrations of BAP (6-Benzyleaminopurine) or Kinetin Kin. (1.0 - 3.0 mgl^{-1}) and combinations of BAP with IAA (0.5+0.5, 1.0+0.5, 1.0+1.0 mgl^{-1}) were used for shoot bud induction and multiplication. After four weeks of inoculation, shoot bud

induction percentage and mean number of shoots per explant were recorded. In each treatment, 10 explants were used and the experiment was repeated thrice for reproducibility. Indirect shoot regeneration (Callus induction and Indirect Shoot formation)

Callus induction

For callus induction, leaf explants were cultured on MS medium fortified with different concentrations of 2,4-D (0.5–3.0 mgl^{-1}), NAA (0.5–1.5 mgl^{-1}), BAP (1.0-4.0 mgl^{-1}), Kinetin (1.0-3.0 mgl^{-1}) alone or combination of BAP with 2,4-D, NAA, IBA and IAA and Kin. with 2,4-D used as indicated in Table 1. Subculturing of induced callus was done by transferring it on same media composition and plant growth regulators concentrations.

Indirect Shoot formation

The green compact callus clumps (200 mg) obtained from callusing medium of each subculture and further cultured onto MS medium supplemented different concentrations of BAP (1.0-3.0 mgl^{-1}) or Kin. (0.5-2.0 mgl^{-1}) and BAP (1.0 mgl^{-1}) in combination with IAA (0.2, 0.5 1.0 mgl^{-1}) and incubated up to 10 weeks. The obtained shoot clumps were excised and sub-cultured in culture tubes (150x25 mm^2) containing same medium for further growth and development. Cultures were incubated under same conditions as mentioned earlier. The data for regeneration frequency, average number of shoots produced per callus clump and length of shoot at the end of fourth week were recorded.

***In vitro* rooting and Acclimatization**

5-7 cm long individual regenerated shoots were excised from the shoot clump and transferred to MS medium containing various concentrations of IAA, IBA, and NAA for *in vitro* root formation. After three weeks, root induction percentage, number of roots per shoot and length of the longest root were measured. Plantlets with well-developed roots were transplanted into plastic cups containing soil: coco peat at a ratio of 1:1 and incubated in culture room for 2 weeks at 27±2°C and 60-70% RH then after they were transferred into green house. The survival ratio of the micropropagated plants were recorded after five weeks of acclimatization.

Statistical analysis

The oneway analysis of variance (0.05% significance level) was carried out to analyze the recorded data for all the experiments. The significant differences between the means were further analyzed with Duncan's multiple range test [13].

Evaluation of Genetic fidelity

Three randomlyselected *in vitro* raised plants from both the pathways i.e. direct and in direct shoot regeneration each were used to evaluate their genetic fidelity with that of the mother plant. For analysis of the genetic fidelity, a polymerase chain reaction (PCR) based molecular markers viz. RAPD was used. The total genomic DNA isolation from mother plant as well as the *in vitro* regenerated plants was done separately from 1 g of the young leaf tissues using the modified cetyl-trimethyl-ammonium-bromide method [14] and screened on UV-visible spectrophotometer to ensure its clarity (A260/280 ratio). For initial screening of DNA samples, The PCR amplification reaction was carried out with 31 random decamer primers in a 25 μL reaction volume consist of 10mM Tris-HCl (pH 8.3), 2.5mM $MgCl_2$, 1mM dNTP mix, 0.2 μM of each primer, 1U of *Taq* DNA polymerase, and 15 to 40 ng of template DNA and 13 µl of sterile water. DNA amplification was performed in a thermal cycler machine using the following PCR conditions with initial denaturation at 94°C for 60 sec, followed by 40 cycles consisted of denaturation at 94°C for 1 min, annealing at 45°C for 60 sec and extension at 72°C for 2 min and the final extension was carried out at the same temperature for 6 min.. After completion of PCR cycles, the amplicons were stored at 4°C until further use [15]. The amplified product was checked in 1.5% agarose gel electrophoresis and obtained bands were visualized in gel documentation system. Twenty RAPD primers were randomly selected for RAPD analysis, of which 10 primers were finally chosen for the clonal fidelity assessment as they produced clear and reproducible bands. Only clear and reproducible bands were scored manually, and the visible amplicons with the similar migration were considered homologous fragments.

Results and Discussion

The cultures with MS medium and devoid of plant growth regulator (PGR) failed to induce callus or shoots, whereas the MS medium fortified with PGR resulted into callus formation as well as shoot differentiation as reported by Senapati *et al.,*[16].

Direct shoot regeneration

Direct shoot regeneration was achieved directly using nodes as explants. Multiple shoots were induced from Nodal explants when inoculated on MS medium fortified with various concentrations of BAP and Kin, individually or in combination with IAA (Table I). Among all the treatments applied, MS medium supplemented with combination of BAP with IAA induced optimum number of shoots significantly in compare to other treatments. BAP with IAA (1.0 +1.0 mgl^{-1}) induced the significantly highest shoot regeneration frequency (96 ± 2.4%) with maximum number of shoots per explant (13.4 ± 0.4) and shoot length (7.2 ± 0.1 cm) (Table I). However, BAP (1.0 mgl^{-1}) alone was also gave better results for the number of shoots per explants, it was lower at the same concentration of kinetin. It was observed that as the concentration of PGRs increased the regeneration frequency, number of shoots per explants and shoot length also increased. In both the type of concentrations used, combined effects of BAP+IAA favored the highest response in terms of mean shoot number and mean shoot length.Similar results as current study includes have also been reported in *Celastrus paniculatus*[9]. Cytokinin along with auxin influences the regeneration types (direct or indirect) and also regulates the organ differentiation [12]. Similarly, the combined effect of BAP and IAA positively enhance adventitious shoot induction is reported in *Hemidesmus indicus* [17], *Aloe pruinose* [18] and *Ceropegiaevansii*[19]. Cytokinins required for *in vitro* axillary shoot induction and proliferation but type of cytokinins and its optimal concentration varies with the system [20].

Indirect shoot regeneration

Callus induction was observed within two weeks of culture at the cut end of leaf explants in all the concentration tried as per Table II. 1.0 mgl^{-1} BAP produced maximum callus induction with 100±0.00% of growth frequency followed by culture treated with 1.0 mgl^{-1} 2,4-D (98.00±2.00%). The green, hard and compact callus was obtained on MS medium supplemented with 1.0 mgl^{-1} BAP. Subsequently, the induced callus were sub-cultured up to two passage at regular interval of 2 weeks on the same medium which resulted into proliferated mass of callus. Further, during second passage of subculturing, shoot bud regeneration was initiated and subsequently it developed into shoots only in MS medium with BAP, Kin. and combination of BAP+IAA (Table III). The highest number of shoots/explant (23.2±0.20) was recorded in sole concentration of BAP (1.0 mgl^{-1}) with 100% growth response and 9.1±0.35cm shoot length. Consequently, increased concentrations of BAP showed less percent growth response, mean number and length of shoots. In the present study, lowest growth response was observed in MS fortified with combination of BAP and IAA (1.0+1.0 mgl^{-1}). The superior effect of BAP on multiple shoot bud regeneration as well as shoot elongation in cotton was proved by Prem Kumar *et al*., [21].Current study shows the significant effect of BAP with different concentration on indirect shoot regeneration. The superior effect of BAP on multiple shoot bud regeneration as well as shoot elongation in cotton was proved by Prem Kumar *et al*., [21]. Similar observations on the superiority of BAP over other cytokinins have been reported for *Psoralea corylifolia*and *Withaniacoagulans*shoot regeneration [22]. Similar types of results were reported by Sharada *et al.,* [23] in *Celastrus.* An earlier study also suggested that the stimulatory effects of BAP on shoot bud differentiation [4]. BA alone caninfluence shooting was noted by Ahmad *et al.,*[24] in *P. nigrum* is also in agreement of our recorded results.

***In vitro* rooting and Acclimatization**

Well-developed and elongated shoots obtained either from direct or indirect shoot regeneration were subsequently transferred into rooting medium in which MS medium supplemented with different concentrations of IBA and NAA alone for root formation (Table IV). Root induction was observed from the well-developed shoots, after 9-10 days of culture, hence complete root development was occurred after 2 weeks. The percentage of root induction frequency and the average number of roots per shoot and the length of roots were significantly varied and depended upon concentration of auxins tried. Among three auxins tested, NAA (2.0 mg/l) induced highest root induction frequency (84.00±2.44%) with maximum number of roots 5.2±0.20 and maximum root length (3.1±0.12cm). In all concentrations

of NAA, first little callusing was observed at basal portion of shoots. Whereas, the lowest root induction was found in 1.0 mg/l IBA with 62±2.00% growth frequency. Roots were failed to grow in both the concentrations of IAA (0.5-1.0 mg/l). Hence, from the present study it was observed that the effect of NAA was better than the other auxins in this plant species. From the present study it was observed that the effect of NAA was better than the other auxins in this plant species. Similarly, NAA is more effective for rooting as in many other plant species were reported earlier, *Tinospora cordifolia* [25], *Gymnemasylvestre* [26], *Sesamum indicum*[27],*Rauwolfia serpentine* [28], Rooting in *Celastrus* was initially found difficult but ideal dosage of NAA in MS media promoted profuse rooting in *in vitro* developed shoots after 12 days.

Evaluation of Genetic fidelity

The genomic DNA extracted from *in vivo* and *in vitro* leaf from direct and indirect shoot regeneration of *Celastrus paniculatus*Willd. was further used for RAPD analysis for testing genetic fidelity of mother plants and randomly selected *in vitro* raised plants. The initial screening process using 20 primers out of which depending upon band reproducibility and clarity 8 primers were finally selected which produced 70 numbers of total bands and are obtained in similar manner in randomly collected samples obtained from both indirect and direct pathways. All the 8 primers produced monomorphic bands which confirming the genetic stability among regenerated plants from either directly or indirectly. Figure 2 represents RAPD profile obtained using primer OPC-4. Thehighest number of bands (12) were observed in primer OPC-4 (5′ GTGAGGCGTC 3′) with 412-1965bp amplification range, while primer OPA-1 (5′ ACCCCCGAAG 3′) produced only 5 scorable bands with 412-1965bp amplification range (Table VI, Figure 2). Thehighest number of bands (12) were observed in primer OPC-4 (5′ GTGAGGCGTC 3′) with 412-1965bp amplification range, while primer OPA-1 (5′ ACCCCCGAAG 3′) produced only 5 scorable bands with 412-1965bp amplification range (Table VI, Figure 2). Similarly, Anusha *et al.,* 2015 reported genetic stability assessment of *in vitro* raised clones of *Celastrus paniculatus* by using RAPD analysis. As the RAPD technique is simple as well as cost effective, so, it has been widely used by many researchers in various plant species in *Viola patrinii* [29], in *Steviarebaudiana*[30] and in *Tecomella undulata* [31].

CONCLUSION

A reliable *in vitro* regeneration system for *C. paniculatus* was developed using both direct and callus-mediated shoot induction, accompanied by an evaluation of clonal fidelity. The established regeneration strategy demonstrates strong potential for large-scale propagation of this valuable medicinal species, although further optimization is required for commercial multiplication and successful acclimatization under field conditions. Assessment of genetic uniformity in regenerated plants is crucial to ensure the maintenance of true-to-type characteristics essential for commercial cultivation. Overall, the findings of this study offer a practical solution to support the growing pharmaceutical demand for consistent and high-quality plant-based raw materials.

ABSTRACT

The infestation of stored grains by insect pests such as *Sitophilus granarius* (wheat weevil) leads to significant post-harvest losses worldwide. This study evaluates the efficacy of botanical powders derived from *Coriandrum sativum* (coriander seeds) and *Piper nigrum* (black pepper) as eco-friendly alternatives to synthetic pesticides for controlling wheat weevils. Mortality rate assessments were conducted by exposing *S. granarius* to different concentrations of the plant materials under controlled conditions. Phytochemical screening of the samples revealed the presence of bioactive compounds such as alkaloids, flavonoids, phenolics and essential oils, which are known for their insecticidal properties. The results demonstrated that both *Coriandrum sativum* and *Piper nigrum* exhibited significant insecticidal effects, with increasing concentrations leading to higher mortality rates of *S. granarius*. The findings suggest that these botanicals can serve as sustainable, biodegradable and cost-effective alternatives for the management of wheat weevil infestations in stored grains.

Keywords: *Sitophilus granarius* (wheat weevil), *Coriandrum sativum* (coriander seeds) and *Piper nigrum* (black pepper), Phytochemical screening, Mortality rate)

INTRODUCTION

Wheat (*Triticum aestivum* L.) is one of the most important and widely cultivated cereal crops in the world. Among the various species of the genus *Triticum*, common wheat (*T. aestivum*) is the most extensively grown and consumed (Suryawanshi *et al.,* 2020). Wheat belongs to the grass family Poaceae (Gramineae) and is popularly known as the "King of Cereals" due to its wide adaptability, high yield potential, and multipurpose use. Stored grain insect pests are a major cause of post-harvest losses worldwide, posing serious threats to food security. According to Phillips and Throne (2010), losses due to stored grain insect pests range from about 9% in developed countries to 20% or more in developing countries. In India, nearly 20–25% of food grains are destroyed annually during storage owing to insect pest infestation (Sujeetha et al., 2014).Insects belonging to the orders Coleoptera and Lepidoptera account for maximum post-harvest losses (Sallam *et al.,* 2013). Grain weevils of the genus *Sitophilus* are particularly destructive, with *S. oryzae* and *S. zeamais* prevalent in warmer regions, while *S. granarius* is confined to temperate regions (Sengupta *et al.,* 1984; Thomas *et al.,* 2015).Plant-based powders derived from different plant parts are widely used as eco-friendly insecticides for the management of stored-grain insect pests. Studies have shown that red and black pepper powders effectively suppress major storage pests such as *Sitophilus granarius* and *Rhyzopertha dominica* in stored wheat, causing significant mortality of both immature and adult stages within 15 days (Ashouri and Shayesteh, 2010; Soujanya *et al.,* 2016). One alternative control method is the use of plant extracts which favour natural enemies and necessary for the biological balance. Although the effectiveness of botanical pesticides had already been established by many researchers, the understanding of the use of botanical pesticides in storage pest management systems is limited in most parts of the world Bezabih, (2022).

Objectives

- To find out the mortality rate of the wheat weevil *Sitophilus granarius* byusing *Coriandrum sativum* (Coriander seeds) and *Piper nigrum* (Pepper powder).
- To test the Phytochemicals, present in the samples.
- To study the efficacy of the botanicals for the management of the wheat weevil *S. granarius.*

MATERIALS AND METHODS

A laboratory culture of wheat weevil *Sitophilus granarius* was maintained in the Laboratory of the Department of Zoology, Nirmala College for Women, Coimbatore. The weevils were reared on pesticide free whole wheat grains under controlled conditions of 28 ± 1°C temperature and 70 ± 5% relative humidity. Approximately 200 adults were introduced into one-liter jars containing 500 grams of wheat grains. The jars were sealed with muslin cloth to ensure aeration while preventing insect escape. After a two-week oviposition period, parent insects were removed and the infested grains were retained for subsequent culture. Adults emerging four weeks postoviposition were collected and used for experimental purposes to maintain uniformity in age and physiological status.

Rearing of Test Insect - *Sitophilus granaries*

Adults of *Sitophilus granarius* – wheat weevil species were collected from the laboratory culture.10 insects of *S. granarius* were collected from the stock and released into separate container which is containing wheat *Triticum aestivum*. The wheat weevil, scientifically known as *S. granarius,* was cultured in a controlled laboratory setting using wheat as their food. The lab conditions were maintained at a steady temperature of 27±1°C and a humidity level of 70±1% RH. To start the rearing process, we placed adult beetles from infested grains into plastic containers with disinfected wheat. Once these adult weevils laid their eggs, we took them out of the containers. The newly hatched weevils were then released onto fresh wheat plants for mating and laying more eggs. This whole cycle was repeated every 15 days to ensure we always had different stages of the insects available for our research.

Collection of Plant materials

The *Piper nigrum* was collected from my native place market Coonoor and was shade dried for 1 day, then powdered for experiment. The *Coriandrum sativum* L. was collected in and around my house and was shade dried for 1 day, powdered and stored for the experimental purpose.

Preparation of Plant Extracts

Plant materials of *Coriandrum sativum* - Coriander seeds and *Piper nigrum* Pepper powders were prepared. Each sample (25 grams) was subjected to double extraction with 300 ml of distilled water at room temperature for 48 hours. The extracts were filtered through Whatman's filter paper. The extracts were used for analysis.

Phytochemical Analysis

Phytochemical analysis is the qualitative and quantitative study of bioactive secondary metabolites (alkaloids, flavonoids, saponins, etc.) in plants, crucial for drug discovery, pharmacology and validating traditional medicine.

Statistical Analysis -The data were statistically analyzed for Linear Multiple regression model and ANOVA by SPSS Package.

RESULTS

The following were the results of the data obtained from our study trials by *Piper nigrum* and *Coriandrum sativum* powders in the management of *Sitophilus granarius* in stored wheat *Triticum sativum.* The multiple linear regression analysis indicated a favorable correlation between pepper powder administration and the mortality rate of *S. granarius* in stored wheat during all observation periods. The regression values rose consistently from Day 1 (β = 0.190) to Day 5 (β = 0.385), signifying an escalating mortality response with extended exposure period. (Table-1a). On Day 1, the impact of pepper powder on mortality was positive however statistically insignificant (t = 0.811). Likewise, Day 2 exhibited a non-significant positive correlation (β = 0.230; t = 0.218). On Day 3, the regression coefficient rose (β = 0.264), although the effect remained statistically non-significant (t = 0.478). By Day 4, the impact of pepper powder on mortality became increasingly evident (β = 0.332) and neared statistical significance (t = 1.994). On Day 5, the peak regression coefficient was observed (β = 0.385) and the effect was statistically significant (t = 2.28).

The regression analysis reveals a temporal escalation in the mortality of *S. granarius* subsequent to pepper powder treatment, implying a cumulative toxic effect with extended exposure. The absence of notable effects in the early days may indicate delayed physiological reactions or insufficient initial exposure to the botanical chemical. The nearly significant effect noted on Day 4 and the statistically significant effect on Day 5 indicate that prolonged exposure is essential for pepper powder to demonstrate efficient insecticidal properties. This trend aligns with prior research on botanical insecticides, which typically exhibit delayed toxicity resulting from slow penetration, feeding deterrent or disruption of metabolic processes rather than instant fatality. The data indicate that pepper powder may serve as an efficient botanical control agent against *S. granarius* in stored wheat, especially with enough exposure length. Additional research is advised to investigate dosage optimization, mechanisms of action, and long-term efficacy under storage conditions. The ANOVA demonstrated that the regression model accounted for all observed variation in the mortality of *S. granarius* after treatment with pepper powder (SS = 189.20). Nevertheless, the remaining degrees of freedom were null, inhibiting the calculation of experimental error. (Table-1b). The lack of residual variance indicates that the model might be over-parameterized or reliant on aggregated data.

The mortality response of *Sitophilus granarius* in wheat treated with pepper powder was analyzed using a multiple linear regression model over five exposure periods (Table-2). The model results indicated a positive correlation between exposure length and insect mortality across all days, demonstrating that pepper powder consistently affected mortality over time. The extent and statistical significance of the effect fluctuated throughout different days.

Day 3 had a robust and statistically significant impact on mortality (β = 2.01; t = 3.33), indicating that the insecticidal efficacy of pepper powder peaked after three days of exposure. The effects noted on Days 1 and 2 were minimal and statistically insignificant, suggesting restricted acute toxicity. Likewise, Days 4 and 5 did not demonstrate substantial increases in mortality, indicating that the mortality response plateaued after the peak effect on Day 3. (Table-2a).

The data indicate that pepper powder functions as a delayed-action botanical insecticide, necessitating adequate exposure duration to achieve its optimal lethal impact on *S. granarius*. The lack of notable mortality increases beyond Day 3 suggests that prolonged exposure does not significantly improve efficacy. The regression results underscore the significance of exposure duration in assessing the efficacy of pepper powder, pinpointing the third day as the crucial timeframe for attaining maximum mortality in *S. granarius* under laboratory circumstances.

The ANOVA findings demonstrate that the regression model accounts for the complete variation in the mortality rate of *S. granarius*, evidenced by the regression sum of squares equaling the total sum of squares (SS = 98.800). This indicates an ideal alignment of the model with the observed data. (Table-2b). Nonetheless, the residual sum of squares equals zero, accompanied by zero residual degrees of freedom (df = 0). Consequently, the F-value could not be calculated, and the statistical significance of the model cannot be formally assessed using the F-statistic. This result signifies that the quantity of predictors in the model matches the number of data, leading to an over-fitted or saturated model. Although the model seemingly accounts for 100% of the variation in mortality, the lack of residual degrees of freedom hinders reliable inferences about the overall relevance of the model. The impact of coriander seed powder on the mortality of *Sitophilus granarius* in wheat was assessed utilizing a multiple linear regression model throughout five exposure durations (Table :3). The regression coefficients revealed a positive correlation between exposure length and insect mortality across all days, illustrating the efficacy of coriander seed powder as a botanical insecticidal treatment.

Day 5 demonstrated a statistically significant impact on mortality (β = 2.00; t = 2.68), suggesting that extended exposure substantially intensified the harmful effects of coriander seed powder. Despite the observation of somewhat high beta values on Days 1 and 4, their associated t-values were below the threshold for statistical significance, indicating that these effects lacked the requisite strength to independently affect mortality. The effects noted on Days 2 and 3 were rather mild and statistically insignificant, suggesting minimal mortality during the initial exposure phase. (Table-3a). The ANOVA results demonstrate that the multiple linear regression model elucidating the mortality of *Sitophilus granarius* in wheat treated with coriander seed powder is statistically significant. The regression sum of squares (SS = 294.800) encompassed the total variability in mortality, whereas the residual sum of squares was zero, signifying an exemplary model fit. The calculated F-value of 21.25 further substantiates the significance of the regression model and indicates that the predictor variables collectively have a substantial impact on insect mortality. (Table-3b). The elevated mean square value for regression (MS = 98.267) in contrast to the minimal residual mean square indicates that exposure time substantially accounts for variability in death rates.

The results corroborate the model coefficients, indicating heightened mortality with extended exposure to coriander seed powder, especially during the later phases of treatment. The ANOVA results substantiate the assertion that coriander seed powder serves as an efficacious botanical pesticide, with mortality significantly influenced by exposure length. The regression analysis indicates that exposure time significantly influences the efficacy of coriander seed powder, with peak mortality recorded on the fifth day of treatment. Multiple linear regression analysis was utilized to assess the impact of coriander seed powder on the mortality of *Sitophilus granarius* in wheat during five exposure periods (Table-4). The model coefficients demonstrated varying impacts of exposure length on insect mortality. A statistically significant positive effect was noted on Day 4 (β = 2.00; t = 2.422), demonstrating that coriander seed powder significantly increased mortality following four days of exposure. Day 5 exhibited a positive beta coefficient (β = 1.00); nevertheless, the effect lacked statistical significance, indicating a moderate rise in mortality without more escalation. The effects noted on Days 1 and 3 were favorable yet statistically insignificant, suggesting minimal early and mid-stage toxicity. Conversely, Day 2 displayed a negative beta coefficient (β = −1.00), indicating a transient decrease or variation in mortality response. The low absolute t-value suggests that this impact was

statistically insignificant and may result from biological variability or experimental noise rather than a genuine antagonistic effect.

The regression results indicate that coriander seed powder has a delayed and stage-specific insecticidal effect, with notable mortality observed after four days of treatment. The data indicate that adequate exposure period is crucial for the efficient management of *S. granarius* utilizing coriander seed powder under storage circumstances. (Table-4a). The ANOVA results indicate that the multiple linear regression model elucidating the mortality of *Sitophilus granarius* in wheat treated with coriander seed powder accounted for all variability in mortality, as evidenced by the regression sum of squares equaling the total sum of squares (SS = 162.000). The residual sum of squares was 0, with no residual degrees of freedom, signifying an impeccable fit of the model to the observed data. (Table-4b). None the less, because to the lack of residual degrees of freedom, the F-value could not be calculated and the overall statistical significance of the regression model could not be formally assessed. This result indicates that the model is saturated, presumably due to the number of predictor variables matching the number of observations. The ANOVA results indicate that exposure length entirely accounts for the difference in *S. granarius* mortality under coriander seed powder treatment; nevertheless, caution is needed in interpreting these data. The absence of residual variance constrains inferential validity and underscores the necessity for further observations or replications to facilitate accurate calculation of experimental error and rigorous statistical analysis The positive Phytochemical test results indicate that both coriander powder and pepper powder contain carbohydrates and flavonoids, suggesting their role as sources of energy and bioactive antioxidant compounds. (Table-5). The presence of proteins with aromatic amino acids in coriander powder indicates its nutritional value. The detection of anthraquinones and saponins in pepper powder indicates that pepper possesses additional bioactive constituents, which may contribute to its medicinal properties such as antimicrobial, digestive, and therapeutic activities. Overall, the results indicate that pepper powder exhibits a richer profile of secondary metabolites compared to coriander powder, while both samples show nutritional and functional importance.

DISCUSSION

Phytochemical analysis of the *Coriandrum sativum* extract revealed several active compounds, including 1,8-cineole, linalool, α-terpineol acetate, butanoic acid and croweacin, which were detected in significant proportions relative to other constituents. The observed insecticidal activity of *C. sativum* may be attributed to these bioactive compounds and their fatty acid derivatives, as also noted by Park *et al.,* (2003). Research showed that pepper powder had significant contact toxicity and oviposition deterrent activities against *Sitophilus oryzae* and could kill insects effectively in 5-7 days at certain concentrations, (Kalpanadevi and Sumithra Devi, 2013). Islam *et al.,* (2009) reported that the seeds, oils and extracts of *Coriandrum sativum* possessed insecticidal property against stored grain insect pests but in the present study it was proved to be the least effective among the other treatments resulting in 38.16% reduction in grain weight loss. A similar observation was made for the activity of hydroethanolic extracts. However, aqueous extracts were low in these phytochemicals making water an inappropriate solvent for extraction of polyphenols and flavonoids, (Azmir *et al.*, 2013).

CONCLUSION

The present study reveals that *Piper nigrum* and *Coriandrum sativum* powders possess important insecticidal and repellent assets against *Sitophilus granarius*, highlighting their potential as effective botanical substitutes for stored-grain pest management. Treatments derived from these plants reduced adult survival and infestation levels, indicating their ability to interrupt the life cycle and feeding activity of the pest. Compared to synthetic insecticides, the use of *P. nigrum* and *C. sativum* offers returns such as biodegradability, lower environmental impact and reduced risk of chemical residues in food grains. Overall, these findings support the integration of plant-based insect control

agents into sustainable and eco-friendly grain protection approaches, while further research on formulation, dosage optimization and long-term effectiveness is recommended for practical application.

ABSTRACT

Cyathocline purpurea[Buch.-Ham. ex D.Don] Kuntze (Asteraceae) is a widely distributed South Asian weed traditionally used in indigenous medicine. Despite its ethnomedicinal relevance, a critical synthesis of its phytochemical and pharmacological properties remains limited. This review systematically evaluates reported secondary metabolites, isolated bioactive compounds, biological activities, and emerging molecular docking evidence associated with this species. Phytochemical investigations indicate the presence of terpenoids, flavonoids, sesquiterpene lactones, and phenolic compounds. Experimental studies demonstrate that extracts and purified constituents exhibit antioxidant, anti-inflammatory, antihyperglycemic, antibacterial, cytotoxic, ovicidal, and larvicidal activities under in vitro and experimental conditions. Preliminary in silico analyses further suggest potential interactions between selected phytoconstituents and biologically relevant molecular targets. However, most findings are derived from preliminary screenings, with limited mechanistic insights and insufficient in vivo and clinical validation. Future research should prioritize extract standardization, toxicity assessment, pharmacokinetic profiling, and molecular pathway elucidation to substantiate therapeutic relevance. Overall, this review consolidates current evidence, identifies research gaps, and provides future directions for systematic investigation of *Cyathocline purpurea* as a potential source of bioactive compounds.

Keywords: *Cyathocline purpurea*, Extraction techniques, Bioactive compounds, Biological activity, Molecular docking

INTRODUCTION

Strong traditional medical systems such as Chinese, Ayurvedic, and Unani have been around for the past 2500 years and are primarily associated with the eastern continent[1]. Traditional medical systems make considerable use of plants as raw materials for several medication formulations. The presence of bioactive elements such alkaloids, tannins, flavonoids, and phenolic compounds accounts for the plant material's therapeutic value [2]. According to [3] and [4],weed are beneficial to humans since they provide food, shelter, medicines, aesthetic value, erosion control, organic matter, and mineral fertilizers for soil. Over 25,000 species of plants that are in the Asteraceae family are abundant in biologically active secondary metabolites.[5,6]. The Asteraceae family is widely recognized for its medicinal qualities and therapeutic applications. *Cyathocline purpurea*(Buch.-Ham. Ex D.Don) Kuntze are widespread weed found throughout south Asia that are from Asteraceae family, which significant for medicine. Morphologically, it is a slender, upright herbaceous annual, attaining heights of approximately 20-50 cm. Soft hair covers a branched, grooved stem. The entire plant has a powerful scent. Stalkless leaves are alternately have tooth structure, and are 3-12 cm long with silky hair covering them. At the tips of branches, corymbs of flowers are found. Purple flower heads are 5 to 8 centimetres in diameter. In the Himalaya (From Kashmir to Bhutan), Assam, India, Burma, Thailand, Indo-China, and China, this plant is extensively dispersed [7-11].

*Cyathocline purpurea*phytochemical composition has to be studied because it contains several unique compounds that haven't been thoroughly studied yet as of [12]. It has pharmacological, antibacterial, antiprotozoal, antiviral, antifungal, and antifertility properties. [10]. For many years, *Cyathocline purpurea* has been used historically to treat a variety of illnesses, including cancer [10]. In traditional Chinese medicine, *Cyathocline purpurea*(Compositae), also referred to as "Hong Hao Zhi," is utilized as a herbal cure for conditions such as human tuberculosis, malaria, haemorrhage, rheumatism, swelling, and anti-inflammatory disorders [13]. *Cyathocline purpurea* has historically been used for its antibacterial, anthelmintic, and hypotensive qualities[14]. An examination of the literature showed the following chemical constituents: santamarine, 6 a-hydroxy-4[14], 10[15]-quaianadien-8a-, 12-olide [15] and sesquiterpenelactones, eudesmanolide, isoivangustin, and guaianolide [16]. *Cyathocline purpurea* was used to isolate the compounds 9b-acetoxycostunolide and 9b-acetoxyparthenolide, which demonstrated strong anticancer effects in vitro[13]. Four plant extract have been added to various medicine formulation to increase their use as primary source of healthcare by 80% of the global population at large. [17,18].The Present review focuses on exploring the bioactive compounds isolated from *Cyathocline purpurea* and their pharmacological potential. Scientific classification, Vernacular names and local names of the*Cyathocline purpurea*shown in Table 1[19, 20].

Extraction Methods of Phytochemicals

The process of extracting medicinally active chemicals from plant parts involves selecting solvents and following certain methods to separate the active compounds, leaving the insoluble molecules behind. Extraction of plant compounds generally involves the diffusion of analytes across the cellular barrier, followed by their removal from the matrix into an appropriate extraction medium [21,18]. The extraction of natural products typically involves the following steps: [1] the extraction medium penetrates the solid plant material., [2] Bioactive compounds dissolve into the permeating liquid., [3] This dissolved constitutes migrate out of the plant matrix., [4] finally, the extracted compounds are collected for further analysis [21]. Various extraction methods show the yield of *Cyathocline purpurea*is shown in Table 2.

Phytochemical analysis

Primary metabolites including sugars, amino acids, and nucleic acids are fundamental to essential cellular processes such as growth, respiration, reproduction, and energy storage in all living oranganisms. In contrast, secondary metabolites originate from primary metabolic pathways and were first introduced [28,29], with Czapek later referring to them as a end-products[30]. These compounds are not vital for basic survival but contribute significantly to plant plant defense and have long been utilized in traditional medicine systems [31]. Presence of various phytochemicals in

solvents shown in Table 3. The quantitative tests shows that 0.869µg/mg atropine equivalent alkaloids and 0.574 µg/mg gallic acid equivalent phenols [22].

Different techniques to isolation and characterization of Bioactive compounds

In recent decades, various phytochemical studies have successfully isolated a broad range of natural compounds. These bioactive substances such as phenols, coumarins, terpenoids have been identified through advanced spectroscopic techniques, including TLC, HPLC, and both proton [^{1}H NMR] and carbon [^{13}C NMR] nuclear magnetic resonance methods [32]. [15] By using repeated column chromatography, two fractions containing sesquiterpene lactones were identified by analysis. From *Cyathocline purpurea,* have isolated two novel sesquiterpene lactones: isoivangustin, a eudesmanolide, 6α-hydroxy-4 [14], 10[15]-guainadien-8α, 12-olide, a guaianolide.[33] reported a novel guianolide compound that was originally identified by nagasampagi and colleagues in 1981. This compounds, isolated from *Cyathocline purpurea*, was characterised as 6α-hydroxy-4[14],10[15]-guainadien-8α,12-olide. Then extracted the crystalline form of the same chemical from *Cyathocline purpurea*. The stereochemistry had to be revised because X-ray examination of the crystal structure revealed that it was 6α-hyroxy-4 [14], 10[15]-guainadien-8α, 12-olide. [14]A total of 25 compounds was identified in the root oil of *Cyathocline purpurea* through GC-MS analysis, accounting for 90.1% of total oil composition. The retention Index, an MS library search, and an examination with MS literature data were used to identify the constituents. The majority of the oil [58.0%] was made up of phenyl derivatives, with thymohydroquinone dimethyl ether having the highest percentage [57.4%]. 18.3% of the hydrocarbons were sesquiterpenes, with b-selinene making up the majority at 14.0%. 11.4% were oxygenated sesquiterpenes and 2.4% were oxygenated monoterpenes. [24]] by using a liquid-solid separation chromatographic method, the extract[15g] was further fractionated into several fractions.

The anti-inflammatory activity of these fractions was evaluated using the carrageenan-induced paw edema model in wistar rats. Column chromatography was used to analyze the 30% acetate in petroleum ether fraction that was the most active. Petroleum ether served as the initial mobile phase, with ethyl acetate added in increasing polarity. The eluted sub-fractions were analysed by Thin Layer Chromatography [TLC] using a petroleum ether;ethyl acetate [7;3] solvent system. Following that, the sub-fractions exhibiting comparable bands were combined, and their anti-inflammatory properties were examined. The most anti-inflammatory efficacy was seen in one of the fraction. Afterthat Isoivangustin [42] was obtained by preperative thin layer chromatography after removed contaminants from obtained fraction. Isoivangustin structure was determined using spectral analysis employing IR, MS, ^{1}H-NMR, 13-NMR, and DEPT. [27] studied the five fractions were obtained by pooling similar fractions using Thin layer chromatography: 1.A[0.28g], 2.A[0.56g], 3.A[0.50g], 4.A[0.46g], and 5.A [0.19g]. Hexane:Ethyl acetate [7:3] was the component that was present in a significant amount as indicated by fraction 2.A [0.56g], which had an RF value of 0.75 on its thin layer chromatography. The pure compound [26.0 mg] was isolated from fraction 2.A through repeated preparative Thin Layer Chromatography using a hexane:ethyl acetate [7:3] solvent system. Its purity was confirmed by ^{1}H, ^{13}C-NMR spectroscopy along with TLC analysis. By comparing its physical and spectroscopic data with published literature, the isolated compound's stereochemistry and structure were determined to be 6α-hydroxy-4 [14], 10[15]-guainadien-8α, 12-olide.

[34] stated that the 5.0% acetone fraction contained the highest yield of the SRCP1 chemical as determined by thin layer chromatography. After gel chromatography, a 5.0 g fraction was further purified through silica gel column chromatography using petroleum ether and ethyl acetate in a 7:3 [v/v] ratio as the mobile phase. On the TLC plate, the pure chemical SRCP1[0.2g] has an RF value of 0.6. The observed UV-VIS spectrophotometric examination findings demonstrate the detection of a single peak showing the compound utmost purity with an absorbance of 1.481 and a λmax at 204 nm. By using HPLC, the optimum SRCP1 concentration in petroleum- ether extract was found to be 289.9246 µg/mg, with an RF value of 4.3 minutes. According to [11], GC-MS analysis of *Cyathocline purpurea*extract identified 17 phytochemical constituents with varying chemical profiles. The dominant compound was pentadecanoic acid, 14-methyl-, methyl ester, comprising over 30% of the extract. Other notable compounds present in moderate to low concentrations included methyl oleate, methyl stearate, 2',5'-dimethoxypropiophenone,

and α-cadinol, Additionally, sesquiterpenes such as α-cubebene, α- and δ-cadinene, β-cubebene, γ-cadinene, and nonadecanoic acid were also detected in measurable amounts. Gas chromatography GC-FID and gas chromatography- mass spectrometry [GC-MS] techniques were used to analyse the essential oils of *Cyathocline purpurea* that were extracted using hydrodistillation from the flowers, leaves, stems, and roots. 34-39 compounds from GC-MS techniques were used to analyse the essential oils of *Cyathocline purpurea* that were extracted using hydroidstillation from the flowers, leaves, stems, and roots. The main components varied greatly by plant part and included ionone, lavandulyl acetate [31.5%], and 2,5-dimethoxy p-cymene [62.6%]. Particularly in the flower and stem extracts, the oil were abundant in oxygenated sesquiterpenes [26].

Evaluative Studies

Antimicrobial activity

Medicinal research often investigates plant-derived antimicrobial because they tend to exhibit minimal side effects.As possible antimicrobial agents, a lot of researchers have recently concentrated on studying plant and microbial extracts, essential oils, pure secondary metabolites, and newly synthesized compounds [35, 36,37]. [38] the study found that the essential oil of *Cyathocline purpurea*inhibits the growth of *Bacillus subtilis* at a very low concentration of 25 µl, and that it inhibits the development of *Pseudomonas aeruginosa* at a low concentration of 50 µl. *Bascillus subtilis*[NCIM 2635] has an inhibitory zone of 1.1 mm when exposed to 25 µl of essential oil. In contrast, *pseudomonas aeruginosa* [NCIM 5032] has an inhibitory zone of 1.3 mm in 50 µl. *Cyathocline purpurea*oil exhibits superior antibacterial action even at low concentrations. [14] evaluated the antimicrobial potential of *Cyathocline purpurea*root essential oil against plant pathogenic bacteria. The study revealed that the oil exhibited activity primarily against Gram-positive bacteria, while Gram-negative strains showed resistance. As the Minimum Inhibitory concentration [MIC] and Minimum Bactericidal Concentration [MBC] value were identical, only MBC data was represented. *Micrococcus flavus* shows the highest sensitivity with an MBC of 0.2670 mg/mL. In contrast, *Bacillus subtilis* was less sensitive, requiring 0.5770 mg/mL for bactericidal action. *Micrococcus luteus* and *Staphylococcus aureus* exhibited moderate sensitivity, with MBC values of 0.3670 mg/mL and 0.4270 mg/mL, respectively. Few studies have revealed antibacterial activities of *Cyathocline purpurea* and not any fungal activity has been done yet, thus it should be further explored in detail against diverse microbial and viral species.

Antioxidant activity

A variety of techniques have been used to assess these moiety' potential as antioxidants. For many organisms to produce energy to power biological processes, oxidation is necessary. However, many diseases, including cancer, atherosclerosis, and rheumatoid arthritis, are brought on by the unchecked generation of free radicals derived from oxygen [39]. Antioxidants scavenge the DPPH radical by donating a hydrogen atom, resulting in the decreased DPPH-H [40]. [23] revealed that the IC_{50} value of the methanol extract of *Cyathocline purpurea*demonstrated more antioxidant potential, while the petroleum extract of *Cyathocline purpurea*demonstrated moderate antioxidant potential with lower activity for the aqueous extract of *Cyathocline purpurea*. [27] the research revealed that the IC_{50} of 12 olide for hydrogen peroxide, DPPH, and hydroxyl radical scavenging activity were 87.5µg/ml, 76µg/ml, and 71µg/ml, respectively. Consequently, it was proposed that *Cyathocline purpurea* possesses strong antioxidant properties.

Anti-inflammatory

The most common indicator of illness, inflammation is also a basic biological process that involves intricate pathways that are frequently brought on by the breakdown products of bacteria from a variety of microorganisms, including viruses [double-stranded RNA], fungi [zymosans], lipopeptides, lipopolysaccharides, peptidoglycans, formylmethionyl peptides, flagellin, and microbial DNA], or even the body's own cells when they are damaged or die [41,42]. [27]found evidence to support the theory that olide's capacity to reduce inflammation may stem from its role in the metabolism of arachidonic acid. *Cyathocline purpurea*may have anti-inflammatory properties because of guaianolides found in sesquiterpene lactones. The hydroxyl group in 6αhydroxyl-4[14], 10 [15]-guainadien-8α, 12

olide may be reason for its anti-inflammatory in-vitro and in-vivo antioxidant activities. [23] studied with methanol extract of *Cyathocline purpurea*[400mg/kg], notable analgesic and anti-inflammatory effects were noted. *Cyathocline purpurea* methanol extract [100, 200, and 400mg/kg] minimized paw edema in an investigation using carrageenan in a cotton pellet model, it also decreased the weight of granuloma in a dose-dependent manner. *Cyathocline purpurea*'s aqueous extract lacked any action, however its petroleum extract had modest analgesic and anti-inflammatory properties. [24]] found that the most active component causing its anti-inflammatory action was isoivangustin, a sesquiterpene lactone; its anti-inflammatory impact may be mediated by TNF-α suppression.

Cytotoxic Activity Against Cancer Cell Lines

Natural products have contributed significantly to drug discovery, with more than 60% of currently used anticancer drugs being derived from or inspired by natural sources [42,44]. Historically, plant-derived secondary metabolites have played an important role in the development of therapeutic agents. Over the past three decades, natural products have attracted considerable attention as potential sources of cytotoxic and antitumor agents [45; 46; 47]. [34] evaluated the cytotoxic activity following a 24-hour treatment period and reported an IC_{50} value of 9.98 μg/mL, which was lower than that of the petroleum ether extract. For comparison, actinomycin D exhibited an IC_{50} value of 8.5 μM under similar conditions. The study further indicated that the isolated pure compound SRCP1 demonstrated stronger cytotoxic activity than the corresponding crude extract. [13] assessed cytotoxic effects using five cultured tumor cell lines, namely L1210 murine leukemia, CCRF-CEM human leukemia, KB human nasopharyngeal carcinoma, LS174T human colon adenocarcinoma, and MCF-7 human breast carcinoma. The compounds santamarine, 9-acetoxycostunolide, and 9-acetoxyparthenolide significantly inhibited cell proliferation in a concentration-dependent manner. Among the tested cell lines, KB cells showed the highest sensitivity, suggesting selective cytotoxic potential against this tumor cell type.

Antihyperglycemic activity

Globally, the prevalence of the disease is rising alarmingly; by 2030, 366 million individuals are expected to have diabetes, compared to an estimated 191 million in 2000 [48]. Due to its natural origin and lower side effects, herbal medicines have gained popularity in recent years for the treatment and control of diabetes in both developed and developing nations. [1]. [22] reported the findings indicated that the benefits of *Cyathocline purpurea* leaf hydroalcoholic extract in rats given alloxan-induced diabetes. According to this study, there was dose-dependent antidiabetic action produced by hydroalcoholic extract of *Cyathocline purpurea*leaves.

Ovicidal and Larvicidal activity

Aedes aegypti Linn. Is a mosquito that transmits dengue, chickenguniya, and yellow fever. Dengue is one of the most common vector-borne infections in the world. The World health Organization [WHO]estimates that 390 million illnesses occur annually, with approximately 96 million showing clinical symptoms[50]. [51] investigated the leaf extract of *Cyathocline purpurea*, which have been shown to have considerable ovicidal and larvicidal action against the dengue vector Aedes aegypti. This study found that the extract induced both significant mortality in larvae and gastrointestinal injury, demonstrating its potential as a natural vector control agent. This application in integrated mosquito management programs as alternative to synthetic insecticides.

Molecular Docking

In recent years, substantial advancements have been made in the techniques of molecular docking and scoring. Molecular docking is used to positioning the computer-generated 3D structure of small ligands into a receptor structure in variety of orientation, conformations and positions[52]. It has become a valuable tool in drug discovery process[53].Molecular docking is a computational technique used to identify a ligand that best aligns with the binding site of protein, both in terms of geometry and energy. Essentially, it examines the compatibility and interaction between two or more molecules, such as a ligand and a receptor. The problem is like solving a 3D puzzle [53,54]. Molecular docking is such a structure-based drug design method that stimulates the molecular interaction and predicts the binding mode and affinity between receptors and ligands. Molecular docking process ligands shown

in Figure 1 [55] [27] Research has indicated that selective COX-2 inhibitors can be linked to various side effects, including gastrointestinal discomfort [such as abdominal pain, nausea, and diarrhoea], headaches, allergic responses like skin rashes and breathing difficulties, as well as an elevated risk of cardiovascular issues. The molecular docking study revealed that 12-olide has a significant affinity towards the COX-2 active sites.[24] reported that molecular docking analysis of isoivangustin at the active site of TNF-alpha converting enzyme [TACE] showed hydrogen binding with amino acid Gly349 and Leu348 like in hydroxamate group of native ligand IH6 which showed hydrogen bonding with same amino acids. Additionally, the octahydronaphthyl ring is accommodated within the hydrophobic pocket shaped by the amino acid residue His405 in the enzyme. Isoivangustin displayed a docking score of -5.341 with the TACE enzyme, suggesting a strong binding affinity at its active sites.

Rationale

Cyathocline purpurea, a history of traditional use, is employed to treat conditions like tuberculosis, malaria, hemorrhage, rheumatism, swelling, and inflammatory disorders. Despite its therapeutic significance, scientific studies on its bioactive compounds remain scarce. The presence of flavonoids, terpenoids, and phenolic substances detected in preliminary studies highlights their possible pharmacological significance. However, the specific roles and mechanisms of these compounds are yet to be fully understood. Addressing this gap is critical to meeting the growing demand for plant-based therapies and developing safer, more effective alternatives to synthetic drugs.

CONCLUSION

Available evidence indicates that *Cyathocline purpurea* has been traditionally employed for the management of various ailments and exhibits a range of biological activities, including antibacterial, antioxidant, anti-inflammatory, antihyperglycemic, cytotoxic, ovicidal, and larvicidal effects under experimental conditions. These activities are primarily associated with the presence of terpenoids, phenolic compounds, and other secondary metabolites. However, current findings are largely based on preliminary in vitro investigations, with limited mechanistic insights and insufficient in vivo and clinical validation. Systematic studies focusing on bioactive compound isolation, molecular mechanisms, toxicity profiling, pharmacokinetic evaluation, and standardized extract development are essential to substantiate its pharmacological relevance. Moreover, comparative phytochemical profiling across different geographical regions and chemotypes may provide deeper insights into variability in bioactivity. Integrating advanced approaches such as metabolomics, target-based screening, and well-designed preclinical models will be crucial to translating preliminary findings into validated therapeutic applications. Future research integrating experimental and translational strategies may facilitate the rational development of C. purpurea–derived bioactive compounds.

ACKNOWLEDGMENT

The first author, Trupesh Revad, gratefully acknowledges the financial support provided by the Council of Scientific and Industrial Research (CSIR), New Delhi, India, through the CSIR-UGC NET Senior Research Fellowship (SRF) [File No. 09/0070(18080)/2024-EMR-I].The authors sincerely thank the Department of Botany, Bioinformatics and Climate Change Impacts Management, Gujarat University, Ahmedabad, India, for providing the necessary facilities and support to carry out this work.

Table 1: **Scientific Classification, Vernacular Names and Local Names of *Cyathocline purpurea***

Classification [Bentham and Hooker]		**Vernacular names**		**Local names**	
Category	**Classification**	**Language**	**Vernacular Name**	**Region**	**local Name**
Class	Dicotyledonae	Hindi	Bandhaniya	Tamil Nadu	Kattu Kothamalli
Sub-class	Gamopetalae	Marathi	Gangotra	Andhra Pradesh	Adavi Kothimeera
Series	Inferae	Nepali	Gal Phulle	West Bengal	Bon Dhone
Order	Asterales	Assamese	Gal Phule	Karnataka	Kaadu Kothambari
family	Asteraceae	Gujarati	Okharad, Gangotri	Odisha	Ban Dhania
Genus	*Cyathocline*	-	-	-	-
Species	*Cyathocline purpurea*	-	-	-	-

Table 2: Various Extraction Methods Andextractive Yield

Sr No.	**Extraction method**	**Plant part**	**Solvent**	**Yield**	**Reference**
1.	Maceration	Leaves	Acetone	-	[11]
		Whole plant	Pet. ether	1.80%	[10]
			Chloroform	1.23%	
			Ethyl acetate	2.03%	
			Ethanol	4.43%	
		Leaves	Ethanol	6.55%	[22]
		Whole plant	petroleum ether	3.3%	[23]
			Methanol	4.7%	
			aqueous	6.7%	
		Whole plant	Methanol	6.9 %	[24]
		Whole plant	Methanol	6.7%	[25]
2.	Hydro-distillation	Roots	Aqueous	0.02%	[14]
		Flowers	Aqueous	0.2%	[26]
		Roots		0.14%	
		Stems		0.08%	
		Leaves		0.03%	
3.	Cold percolation	Aerial part	Methanol	-	[27]
4.	Soxhlet apparatus	Leaves Stems and Bark	Hexane, Toluene, Ethyl acetate, Ethanol & water.	-	[12]

Table 3: Phytochemicals Present in Different Solvent Extracts

Solvent/Extract	Phytochemical present	Reference
Petroleum ether	Lipids, terpenoids and steroids	[10]
Chloroform	Saponins, terpenoids and steroids	
Ethyl acetate	Phenols, terpenoids, flavonoids and steroids	
Ethanol	Alkaloids, glycosides, phenols, tannins, flavonoids, saponins and steroids	
Petroleum	Phenol, tannins, alkaloids and flavonoids	[23]
Methanol	Alkaloids, flavonoids, tannins, phenols, glycosides and steroids

ABSTRACT

Sneha Kalpana is a fundamental pharmaceutical dosage form in Ayurveda, wherein lipid media such as Taila (oil) and Ghṛta (clarified butter) are processed with medicinal plant materials to produce therapeutically effective formulations. While most medicated oils are traditionally prepared by **Agni Pāka** (direct heating), classical Ayurvedic literature also describes **Āditya Pāka Taila Vidhi**, a unique pharmaceutical process employing solar energy as the source of heat. This method provides gradual, low-temperature processing and has traditionally been recommended for topical medicated oils used in dermatological disorders. Kutaja (*Holarrhena antidysenterica* Wall. ex A.DC.) and Nimba (*Azadirachta indica* A. Juss.) possess well-documented antimicrobial, anti-inflammatory, antioxidant, antipruritic, and wound-healing properties, making them promising candidates for the development of topical Ayurvedic formulations. To critically review the classical Ayurvedic literature and contemporary scientific evidence pertaining to Āditya Pāka Taila Vidhi and to evaluate the pharmaceutical rationale, preparation methodology, standardization requirements, and future research prospects of Kutaja Nimba Taila. This study was conducted. Classical Ayurvedic texts, including *Charaka Saṃhitā, Suśruta Saṃhitā, Aṣṭāṅga Hṛdaya, Śārṅgadhara Saṃhitā, Chakradatta, Bhaishajya Ratnāvalī, Sahasrayoga, Gada Nigraha, Bhāvaprakāśa Nighaṇṭu, Dhanvantari Nighaṇṭu,* and *Kaiyadeva Nighaṇṭu*, were reviewed. Contemporary scientific literature was retrieved from PubMed, Scopus, Google Scholar, ScienceDirect, and CrossRef, together with the Ayurvedic Pharmacopoeia of India (API), Ayurvedic Formulary of India (AFI), and WHO

monographs. Literature concerning Sneha Kalpana, Āditya Pāka, Kutaja, Nimba, medicated oils, phytochemistry, pharmacology, pharmaceutical processing, and quality control was critically analysed. Classical literature recognises Āditya Pāka as a specialised pharmaceutical technique for preparing medicated oils intended primarily for external application. Kutaja contributes steroidal alkaloids, flavonoids, tannins, and phenolic compounds with antimicrobial and anti-inflammatory activities, whereas Nimba Taila functions both as the lipid medium and as a therapeutically active ingredient rich in limonoids and related phytochemicals. The pharmaceutical rationale of Āditya Pāka is consistent with the principles of low-temperature herbal extraction; however, direct comparative studies evaluating phytochemical retention, physicochemical characteristics, or therapeutic efficacy between Āditya Pāka and conventional Agni Pāka are currently lacking. Kutaja Nimba Taila prepared by Āditya Pāka Taila Vidhi represents a pharmaceutically rational formulation derived from classical Ayurvedic principles rather than a named classical formulation. Although supported by traditional therapeutic concepts and the known pharmacological properties of Kutaja and Nimba, the formulation requires comprehensive pharmaceutical standardization, phytochemical characterization, pharmacological validation, toxicological assessment, and well-designed clinical trials before definitive therapeutic conclusions can be established.

Keywords: Āditya Pāka; Sneha Kalpana; Kutaja; *Holarrhena antidysenterica*; Nimba; *Azadirachta indica*; Medicated oil; Solar extraction; Ayurvedic pharmaceutics; Dermatology.

INTRODUCTION

Ayurveda, the traditional medical system of India, has evolved a sophisticated pharmaceutical discipline known as Bhaiṣajya Kalpanā, which encompasses the principles governing the selection, processing, formulation, preservation, standardization, and therapeutic application of medicinal substances. Among the numerous dosage forms described in the Ayurvedic classics, Sneha Kalpana occupies a distinctive position because of its ability to extract, preserve, and deliver therapeutically active phytoconstituents through lipid media such as Taila (oil) and Ghṛta (clarified butter). These formulations are extensively employed for both internal administration and external therapeutic procedures including Abhyanga (therapeutic massage), Nasya (nasal administration), Karṇapūraṇa (ear instillation), wound management, and the treatment of dermatological disorders. Conventionally, medicated oils are prepared by Agni Pāka, wherein herbal paste (*Kalka*), lipid medium (*Sneha Dravya*), and liquid media (*Drava Dravya*) are processed under carefully controlled heating until the characteristic Sneha Siddhi Lakṣaṇas are achieved. This process facilitates the extraction of both hydrophilic and lipophilic phytoconstituents into the lipid phase while improving the stability, bioavailability, and therapeutic efficacy of the finished formulation. Modern pharmaceutical science similarly recognizes lipid-based drug delivery systems as effective carriers capable of enhancing dermal penetration, protecting unstable phytochemicals, and improving the bioavailability of poorly water-soluble compounds.

In addition to conventional heating, classical Ayurvedic literature describes an alternative pharmaceutical technique known as Āditya Pāka Taila Vidhi, in which sunlight serves as the source of thermal energy. Unlike Agni Pāka, this method relies on gradual solar exposure to facilitate the transfer of medicinal constituents into the lipid medium. Classical texts recommend this technique primarily for medicated oils intended for external use in disorders such as Kuṣṭha (skin diseases), Kandu (pruritus), Śvitra (depigmentary disorders), chronic wounds, and scalp diseases. Although the exact physicochemical mechanisms underlying Āditya Pāka have not been fully elucidated, the process conceptually resembles modern low-temperature herbal infusion techniques, where prolonged mild heating is employed to reduce the risk of excessive thermal degradation while allowing gradual extraction of bioactive constituents. Among the medicinal plants widely used in Ayurvedic dermatology, Kutaja (*Holarrhena antidysenterica* Wall. ex A.DC.) and Nimba (*Azadirachta indica* A. Juss.) occupy an important place due to their broad spectrum of

therapeutic properties. Classical Ayurvedic texts describe these drugs as Kuṣṭhaghna (beneficial in skin diseases), Krimighna (antimicrobial), Kandughna (antipruritic), Śothahara (anti-inflammatory), and Vraṇaropaṇa (wound healing). Contemporary pharmacological investigations have demonstrated antimicrobial, antifungal, antioxidant, anti-inflammatory, immunomodulatory, and wound-healing activities, thereby providing scientific support for many of their traditional indications. Neem oil (*Nimba Taila*), in particular, is widely recognised for its therapeutic utility in scalp disorders and serves both as a lipid vehicle and as a pharmacologically active ingredient. The combination of fresh Kutaja leaves processed in Nimba Taila through Āditya Pāka Taila Vidhi therefore represents a pharmaceutically plausible topical formulation. However, it is important to note that Kutaja Nimba Taila is not described as a named formulation in the available classical Ayurvedic texts. Rather, it is a formulation proposed by applying established principles of Āditya Pāka Taila Vidhi together with the documented therapeutic attributes of Kutaja and Nimba.

Consequently, its pharmaceutical characteristics, quality standards, safety profile, and therapeutic efficacy require systematic scientific evaluation before it can be recommended for routine clinical practice. Despite increasing interest in traditional herbal formulations, the available literature predominantly addresses Sneha Kalpana, Kutaja, and Nimba as separate entities. Reviews specifically focusing on Āditya Pāka Taila Vidhi remain scarce, and there is a lack of critical appraisal integrating classical Ayurvedic concepts with contemporary pharmaceutical science. Furthermore, no published comparative studies have comprehensively evaluated Āditya Pāka and conventional Agni Pāka with respect to phytochemical retention, physicochemical characteristics, stability, or therapeutic performance of Kutaja Nimba Taila. This lack of evidence highlights the need for a structured review synthesising classical knowledge and modern scientific perspectives. Accordingly, the present narrative review critically examines the classical Ayurvedic literature related to Sneha Kalpana and Āditya Pāka Taila Vidhi, reviews the pharmacognostic, phytochemical, and pharmacological characteristics of Kutaja and Nimba, presents a proposed Standard Operating Procedure for the preparation of Kutaja Nimba Taila, discusses quality control and standardization requirements, identifies current research gaps, and outlines future directions for pharmaceutical and clinical validation. By integrating traditional Ayurvedic pharmaceutics with contemporary scientific evidence, this review aims to provide a robust conceptual framework for future research on solar-processed medicated oils.

Aim

To critically review the classical Ayurvedic literature and contemporary scientific evidence related to Āditya Pāka Taila Vidhi and to evaluate the pharmaceutical rationale, preparation methodology, standardization requirements, and future research prospects of Kutaja Nimba Taila.

Objectives

- To review the classical concepts of **Sneha Kalpana** and **Āditya Pāka Taila Vidhi**.
- To compile and critically analyse classical references related to solar-processed medicated oils.
- To review the Ayurvedic, phytochemical, and pharmacological properties of Kutaja and Nimba relevant to dermatological applications.
- To propose a standardized pharmaceutical procedure (SOP) for the preparation of Kutaja Nimba Taila.
- To discuss appropriate quality-control measures and analytical approaches for standardization.
- To identify research gaps and recommend future pharmaceutical, pharmacological, and clinical studies necessary for scientific validation.

REVIEW METHODOLOGY

Study Design

The present study was conducted as a narrative literature review to critically synthesize evidence from classical Ayurvedic texts and contemporary scientific literature regarding Āditya Pāka Taila Vidhi and the proposed formulation Kutaja Nimba Taila. Unlike a systematic review, which aims to identify and quantitatively synthesize all available evidence using predefined protocols, the objective of this review was to integrate classical Ayurvedic

knowledge with modern pharmaceutical concepts, identify areas of scientific agreement and uncertainty, and highlight future research priorities. The narrative review design was considered appropriate because the available literature consists of heterogeneous sources, including classical Ayurvedic treatises, pharmacopoeial references, phytochemical investigations, pharmacological studies, pharmaceutical reports, and modern review articles, which are not amenable to quantitative meta-analysis.

Literature Search Strategy

A comprehensive literature search was performed between January and June 2026 to identify relevant classical Ayurvedic references and contemporary scientific publications related to Sneha Kalpana, Āditya Pāka Taila Vidhi, Kutaja, Nimba, herbal oil formulations, and pharmaceutical standardization.

Electronic databases searched included:

- PubMed
- Scopus
- Google Scholar
- ScienceDirect
- CrossRef

To supplement the electronic search, standard reference documents were consulted, including:

- Ayurvedic Pharmacopoeia of India (API)
- Ayurvedic Formulary of India (AFI)
- World Health Organization (WHO) Monographs on Medicinal Plants

Manual searches of reference lists from relevant publications were also performed to identify additional literature not retrieved through electronic databases.

Classical Ayurvedic Sources

Authoritative classical Ayurvedic texts were reviewed to collect information regarding Sneha Kalpana, Āditya Pāka Taila Vidhi, medicinal properties of Kutaja and Nimba, and pharmaceutical procedures related to medicated oils.

The principal classical references included:

- *Charaka Saṃhitā*
- *Suśruta Saṃhitā*
- *Aṣṭāṅga Hṛdaya*
- *Śārṅgadhara Saṃhitā*
- *Chakradatta*
- *Bhaiṣajya Ratnāvalī*
- *Sahasrayoga*
- *Gada Nigraha*
- *Bhāvaprakāśa Nighaṇṭu*
- *Dhanvantari Nighaṇṭu*
- *Kaiyadeva Nighaṇṭu*

These texts were consulted to identify references to Sneha Kalpana, solar-assisted pharmaceutical processing, therapeutic indications of Kutaja and Nimba, and the broader pharmaceutical principles underlying medicated oil preparation.

Search Keywords

The literature search was conducted using combinations of Medical Subject Headings (MeSH), free-text keywords, and Boolean operators (AND/OR).

The principal search terms included:

- "Āditya Pāka"
- "Aditya Paka Taila"

- "Sneha Kalpana"
- "Medicated oil"
- "Solar extraction"
- "Solar infusion"
- "Kutaja"
- "Holarrhena antidysenterica"
- "Nimba"
- "Azadirachta indica"
- "Herbal oil"
- "Ayurvedic pharmaceutics"
- "Dermatological formulations"
- "Dandruff"
- "Seborrheic dermatitis"
- "Topical herbal formulation"

Representative search combinations included:

- "Āditya Pāka" AND "Sneha Kalpana"
- "Holarrhena antidysenterica" AND "Azadirachta indica"
- "Solar extraction" AND "Herbal oil"
- "Kutaja" AND "Dermatology"
- "Neem oil" AND "Pharmaceutical standardization"

Inclusion Criteria

The following publications were included in the review:

- Classical Ayurvedic texts describing Sneha Kalpana, Āditya Pāka Taila Vidhi, Kutaja, or Nimba.
- Peer-reviewed original research articles and review papers.
- Publications concerning phytochemistry, pharmacology, pharmaceutical processing, analytical evaluation, quality control, or therapeutic applications of Kutaja, Nimba, medicated oils, or solar-assisted extraction.
- Official pharmacopoeial documents and WHO monographs.
- Articles published in English.

Exclusion Criteria

The following sources were excluded:

- Duplicate publications.
- Conference abstracts without complete manuscripts.
- Non-peer-reviewed articles lacking scientific validation.
- Publications unrelated to the objectives of the review.
- Studies with inadequate methodological detail or insufficient scientific information.

Period Covered

The review incorporated:

- Classical Ayurvedic literature from the foundational Ayurvedic treatises.
- Modern scientific publications available up to June 2026.

No lower publication date limit was applied because historical Ayurvedic references constitute an essential component of the review.

Data Extraction and Synthesis

Relevant information was extracted and organized under the following thematic categories:

- Classical concepts of Sneha Kalpana
- Classical references to Āditya Pāka Taila Vidhi
- Ayurvedic properties of Kutaja and Nimba
- Botanical and pharmacognostic characteristics
- Phytochemical constituents
- Pharmacological activities
- Pharmaceutical processing
- Standard Operating Procedure (SOP)
- Quality control and standardization
- Contemporary pharmaceutical perspectives
- Research gaps and future directions

Information obtained from classical texts was interpreted in the context of contemporary pharmaceutical science to identify areas of convergence and opportunities for future investigation.

Scope and Comprehensiveness of the Review

The present review aimed to achieve comprehensiveness by integrating evidence from both classical Ayurvedic literature and modern scientific publications. Multiple authoritative classical treatises were examined alongside internationally recognized biomedical databases and standard reference documents, including the Ayurvedic Pharmacopoeia of India (API), the Ayurvedic Formulary of India (AFI), and WHO monographs. No major classical references relevant to Āditya Pāka Taila Vidhi, Sneha Kalpana, Kutaja, or Nimba were intentionally excluded. Modern publications were excluded only when they represented duplicate records, lacked adequate methodological detail, or were not directly relevant to the objectives of the review. Although every effort was made to include the most authoritative and relevant literature available at the time of manuscript preparation, the review was conducted as a **narrative review** rather than a systematic review. Accordingly, it does not claim exhaustive retrieval of every published study. The emphasis was placed on synthesizing evidence most relevant to the pharmaceutical principles, preparation methodology, and scientific rationale of Kutaja Nimba Taila prepared by Āditya Pāka Taila Vidhi.

Limitations of the Review

the review is based predominantly on published literature and therefore reflects the availability and quality of existing evidence. Second, direct experimental investigations evaluating Kutaja Nimba Taila prepared by Āditya Pāka Taila Vidhi are currently lacking. Consequently, certain pharmaceutical interpretations—particularly those concerning enhanced preservation of thermolabile phytoconstituents during solar processing—are based on classical Ayurvedic principles and established pharmaceutical concepts rather than direct experimental validation. Finally, comparative studies evaluating Agni Pāka and Āditya Pāka preparations remain scarce, limiting evidence-based conclusions regarding the relative pharmaceutical advantages of these processing methods.Sneha Kalpana: Classical Concepts and Pharmaceutical Significance Concept of Sneha Kalpana Sneha Kalpana is one of the most important pharmaceutical dosage forms described in Bhaiṣajya Kalpanā (Ayurvedic pharmaceutics). The term *Sneha* denotes lipid substances possessing unctuous, lubricating, nourishing, and penetrating properties, whereas *Kalpana* refers to the systematic pharmaceutical processing of medicinal substances into therapeutically effective dosage forms. In Ayurvedic practice, Sneha Kalpana involves processing lipid media such as Taila (oil) or Ghṛta (clarified butter) with herbal drugs and liquid media to prepare medicated formulations intended for both internal and external administration.

Classical Ayurvedic texts consider Sneha as an ideal pharmaceutical vehicle because it extracts both lipid-soluble and water-soluble phytoconstituents while improving stability, palatability, shelf life, tissue penetration, and therapeutic efficacy. The lipid medium also facilitates the delivery of bioactive compounds to deeper tissues through its Sūkṣma (subtle) and Vyavāyī (rapidly diffusing) properties described in Ayurveda. Consequently, medicated oils are

extensively used in Pañcakarma, dermatology, ophthalmology, otorhinolaryngology, wound care, musculoskeletal disorders, and neurological diseases. Modern pharmaceutical science similarly recognizes lipid-based drug delivery systems as efficient carriers capable of enhancing dermal penetration, improving the bioavailability of poorly water-soluble phytochemicals, protecting unstable constituents from degradation, and enabling sustained release. This convergence between Ayurvedic pharmaceutical principles and contemporary drug-delivery concepts underscores the continued relevance of Sneha Kalpana in evidence-based herbal medicine.

Definition of Sneha Kalpana

Although the wording differs among classical treatises, the concept remains uniform. Sneha Kalpana may be defined as: The pharmaceutical process in which Sneha Dravya (oil or ghee) is processed with Kalka (herbal paste) and Drava Dravya (liquid media) under prescribed conditions until characteristic Sneha Siddhi Lakṣaṇas are attained, thereby producing a stable medicated lipid formulation suitable for therapeutic use. This definition emphasizes that the therapeutic value of Sneha Kalpana depends not only on the medicinal plants employed but also on the pharmaceutical method adopted during processing.

Historical Evolution

The principles of Sneha Kalpana have evolved progressively throughout Ayurvedic literature.

The Charaka Saṃhitā introduced the therapeutic importance of medicated oils and clarified butter in internal medicine and Panchakarma. The Suśruta Saṃhitā expanded their application to surgical practice, wound management, burns, and dermatological conditions. The Aṣṭāṅga Hṛdaya provided practical guidance regarding pharmaceutical preparation and therapeutic indications. Subsequently, medieval texts such as Śārṅgadhara Saṃhitā, Chakradatta, Bhaiṣajya Ratnāvalī, and Sahasrayoga elaborated standardized pharmaceutical methods, proportions of ingredients, stages of processing, and indicators of successful preparation. These texts also describe specialized pharmaceutical techniques, including Āditya Pāka, in which sunlight rather than direct fire serves as the processing medium for selected formulations.

Components of Sneha Kalpana

Classically, Sneha Kalpana consists of three essential pharmaceutical components.

Sneha Dravya

Sneha Dravya constitutes the lipid base of the formulation. Commonly used lipid media include:

- Taila (vegetable oils)
- Ghṛta (clarified butter)
- Vasa (animal fat)
- Majjā (bone marrow fat)

Among these, **Taila** is generally preferred for dermatological disorders because of its superior skin penetration, stability, and suitability for external application.

Kalka Dravya

Kalka refers to finely triturated herbal paste prepared from fresh or dried medicinal plant materials.

Functions of Kalka include:

- Providing concentrated phytochemicals.
- Facilitating extraction during processing.
- Improving interaction between herbal constituents and lipid medium.
- Enhancing therapeutic potency.

The amount of Kalka varies depending upon the pharmaceutical procedure and textual reference.

Drava Dravya

Drava Dravya denotes the liquid medium employed during processing.

Examples include:

- Water
- Swarasa (fresh juice)
- Kwatha (decoction)
- Ksheera (milk)
- Takra (buttermilk)
- Gomutra
- Herbal infusions

The liquid medium assists in extracting water-soluble constituents while enabling their gradual transfer into the lipid phase during processing.

Classical Proportion of Ingredients

The most widely accepted proportion described in Śārṅgadhara Saṃhitā is:

- Sneha : 1 part
- Kalka : 1/4 part
- Drava : 4 parts

This ratio is regarded as the standard formulation for conventional Agni Pāka preparations.

However, formulations prepared through Āditya Pāka Taila Vidhi often differ because solar processing relies on gradual extraction rather than prolonged boiling. Consequently, pharmaceutical optimization of ingredient ratios remains an important area for future investigation.

Types of Sneha Pāka

Classical Ayurvedic pharmaceutics recognizes three principal stages of Sneha Pāka.

Mridu Pāka

- Mild processing.
- Higher residual moisture.
- Preferred for Nasya and delicate procedures.

Madhyama Pāka

- Optimum pharmaceutical stage.
- Most commonly employed.
- Suitable for external and internal therapeutic use.

Khara Pāka

- Extensive processing.
- Minimal moisture.
- Longer shelf life.
- Primarily intended for external application.

Selection of the appropriate stage depends upon therapeutic indication, route of administration, and intended pharmaceutical characteristics.

Sneha Siddhi Lakṣaṇas (Signs of Proper Processing)

Achievement of **Sneha Siddhi Lakṣaṇas** indicates completion of the pharmaceutical process.

Common indicators described in classical literature include:

- Disappearance of frothing.
- Characteristic aroma.
- Absence of residual moisture.
- Smooth consistency.
- Proper colour development.
- Kalka becoming soft, non-sticky, and capable of rolling into a wick.
- Lack of crackling sound when a small quantity is exposed to heat.

These observations continue to serve as important quality indicators during the preparation of medicated oils.

Pharmaceutical Significance of Sneha Kalpana: From a contemporary pharmaceutical perspective, Sneha Kalpana provides several advantages.

Efficient Extraction: The lipid medium extracts lipophilic phytochemicals while the presence of aqueous media facilitates transfer of hydrophilic constituents into the formulation.

Improved Stability: Lipid formulations are generally more resistant to microbial contamination than aqueous preparations and possess extended shelf life when appropriately prepared.

Enhanced Dermal Delivery: Oils improve hydration of the stratum corneum and enhance percutaneous absorption of bioactive compounds, making them particularly suitable for dermatological applications.

Protection of Sensitive Constituents: When processed under controlled conditions, lipid media may reduce oxidative degradation of certain phytochemicals by limiting exposure to excessive heat and oxygen. However, the extent of such protection depends upon the processing method and requires experimental verification for individual formulations.

Sustained Drug Release: The viscous nature of lipid preparations facilitates prolonged contact with affected tissues, thereby enhancing therapeutic effectiveness.

Contemporary Pharmaceutical Perspective: Current research increasingly supports the integration of Ayurvedic pharmaceutics with modern pharmaceutical science. Lipid-based herbal formulations are recognized as promising delivery systems capable of improving drug solubility, enhancing bioavailability, and facilitating controlled release.

In this context, Āditya Pāka Taila Vidhi represents an intriguing traditional pharmaceutical approach that may offer unique advantages for the preparation of topical medicated oils. Nevertheless, many of its proposed pharmaceutical benefits remain to be validated through modern analytical techniques, including physicochemical characterization, phytochemical fingerprinting, stability studies, and comparative evaluation with conventional Agni Pāka preparations.

Relevance to the Present Review

An understanding of the principles of Sneha Kalpana is fundamental for appreciating the rationale behind Āditya Pāka Taila Vidhi. The proposed formulation of Kutaja Nimba Taila applies these classical pharmaceutical concepts while adapting them to a solar-assisted processing technique. This adaptation emphasizes gentle extraction without direct heating and forms the conceptual basis for the pharmaceutical approach discussed in subsequent sections.

Āditya Pāka Taila Vidhi: Classical Foundations and Contemporary Pharmaceutical Perspectives The preparation of medicated oils (Taila Kalpana) occupies a central position in Ayurvedic pharmaceutics due to its versatility, stability, and therapeutic efficacy. Conventionally, most medicated oils are prepared using Agni Pāka, wherein heat generated by direct fire facilitates the transfer of active constituents from herbal materials into the lipid medium. However, classical Ayurvedic literature also describes an alternative pharmaceutical technique known as Āditya Pāka Taila Vidhi, in which solar energy rather than direct fire serves as the processing medium. Although less frequently employed than Agni Pāka, Āditya Pāka represents an important example of the diversity and sophistication of classical Ayurvedic pharmaceutical technology. The method relies on prolonged exposure of herbal materials immersed in oil to natural sunlight, allowing gradual extraction of phytoconstituents under ambient environmental conditions. Traditionally, this technique has been recommended for selected topical formulations intended primarily for dermatological disorders, chronic wounds, scalp diseases, and inflammatory conditions. Interest in Āditya Pāka has increased in recent years because contemporary pharmaceutical science recognizes that processing temperature can influence phytochemical stability, extraction efficiency, oxidative degradation, and the preservation of volatile constituents. Consequently, revisiting this classical technique through modern scientific investigation may contribute to the development of standardized low-temperature herbal formulations.

Etymology and Concept

The Sanskrit term **Āditya** refers to the Sun, while Pāka denotes pharmaceutical processing or maturation. Accordingly, Āditya Pāka literally means processing under sunlight.

Unlike conventional heating methods, the pharmaceutical transformation occurs gradually through continuous solar exposure. The process represents a natural form of extraction in which medicinal constituents diffuse slowly into the lipid medium over several days. From an Ayurvedic perspective, the gradual action of sunlight is believed to facilitate **Sneha Saṃskāra** (pharmaceutical transformation of oils) without exposing the formulation to the intense thermal effects associated with direct fire.

Classical References

Although Kutaja Nimba Taila is not described as a named formulation in the available classical Ayurvedic texts, the pharmaceutical principle of Āditya Pāka is documented in several authoritative references.

Descriptions of solar-assisted processing are found in:

- **Śārṅgadhara Saṃhitā**
- **Chakradatta**
- **Bhaiṣajya Ratnāvalī**
- **Sahasrayoga**
- **Gada Nigraha**

These texts describe pharmaceutical procedures in which medicinal substances are processed by prolonged exposure to sunlight rather than direct heating. Such preparations were primarily recommended for external therapeutic applications, particularly in disorders affecting the skin and scalp. The present formulation therefore represents a pharmaceutically rational adaptation of established classical principles, combining the documented methodology of Āditya Pāka with the well-recognized therapeutic properties of Kutaja (*Holarrhena antidysenterica*) and Nimba Taila (*Azadirachta indica*).

Importantly, Kutaja Nimba Taila prepared by Āditya Pāka Taila Vidhi should not be interpreted as a classical proprietary formulation but rather as a conceptually derived formulation proposed for pharmaceutical standardization and scientific evaluation. Pharmaceutical Principles of Āditya Pāka The pharmaceutical rationale of Āditya Pāka may be understood through the interaction of several mechanisms. Gradual Extraction Continuous solar exposure allows slow diffusion of phytoconstituents from fresh herbal material into the lipid medium. Compared with direct heating, extraction occurs over an extended period, potentially facilitating equilibrium between plant tissues and the oil. Mild Thermal Processing Ambient solar temperatures are generally lower than temperatures encountered during conventional boiling. Consequently, the formulation is subjected to comparatively mild thermal conditions throughout processing. Lipid-Mediated Solubilization The lipid medium dissolves lipophilic constituents while simultaneously facilitating gradual incorporation of phytochemicals released from the herbal matrix. Continuous Pharmaceutical Transformation Repeated cycles of daytime warming and nighttime cooling may influence extraction kinetics and facilitate progressive interaction between herbal constituents and the oil throughout the processing period. Contemporary Scientific Perspective From the standpoint of modern pharmaceutical science, extraction temperature is an important determinant of phytochemical composition.

Numerous studies involving herbal extraction have demonstrated that processing temperature may influence:

- extraction efficiency,
- oxidative degradation,
- essential oil retention,
- stability of thermolabile constituents,
- colour,
- viscosity,
- antioxidant activity.

However**,** no direct experimental studies have yet demonstrated these effects specifically for Kutaja Nimba Taila prepared by Āditya Pāka Taila Vidhi. Therefore, while the pharmaceutical rationale is scientifically plausible, the proposed advantages remain hypotheses requiring experimental validation**.**

Preservation of Thermolabile and Volatile Constituents

Classical Ayurvedic literature suggests that Āditya Pāka provides gentle pharmaceutical processing.

From a modern perspective, lower processing temperatures could theoretically reduce degradation of heat-sensitive phytochemicals and minimize evaporation of volatile constituents compared with direct boiling.

Nevertheless, the present review did not identify direct experimental evidence demonstrating superior preservation of thermolabile or volatile phytoconstituents in Kutaja Nimba Taila prepared by Āditya Pāka.

Accordingly, the present manuscript deliberately avoids presenting this concept as an established scientific fact.

Instead, the available evidence supports the following interpretation:

- Classical texts advocate gradual solar processing.
- Modern pharmaceutical science recognizes temperature-dependent degradation of phytochemicals.
- Whether Āditya Pāka provides superior phytochemical retention remains unknown.

Future comparative analytical investigations using HPTLC, HPLC, GC–MS, LC–MS/MS, and metabolomic profiling are required to verify this hypothesis.

Comparison Between Agni Pāka and Āditya Pāka

Both pharmaceutical techniques are intended to prepare medicated oils but differ considerably in their processing characteristics. Although theoretical pharmaceutical differences exist, published comparative studies directly evaluating Agni Pāka and Āditya Pāka formulations remain extremely limited

Advantages

Potential pharmaceutical advantages include:

- Natural solar-assisted processing.
- Elimination of direct heating.
- Reduced energy consumption.
- Simplicity of preparation.
- Potential compatibility with environmentally sustainable pharmaceutical practices.
- Conceptual suitability for heat-sensitive herbal formulations.

However, these potential benefits require confirmation through controlled pharmaceutical investigations.

Limitations

Several limitations currently restrict wider scientific acceptance of Āditya Pāka.

- Absence of standardized operating procedures.
- Variation in climatic conditions.
- Lack of standardized solar exposure parameters.
- Limited analytical characterization.
- Lack of comparative pharmaceutical studies.
- Insufficient stability studies.
- Absence of pharmacokinetic investigations.
- Very limited clinical validation.

These limitations highlight the need for systematic pharmaceutical standardization.

Current Evidence

The available literature primarily consists of:

- classical Ayurvedic descriptions,
- pharmacological studies of Kutaja,
- pharmacological studies of Nimba,
- general studies on herbal extraction.

No published investigations were identified that directly evaluated:

- phytochemical profile of Kutaja Nimba Taila,
- physicochemical characteristics following Āditya Pāka,
- comparative pharmaceutical evaluation against Agni Pāka,
- randomized clinical trials of the finished formulation.

Therefore, the pharmaceutical superiority of Āditya Pāka remains unproven and should be regarded as a promising area for future research rather than an established conclusion.

Pharmaceutical Relevance to the Present Formulation

The proposed preparation of Kutaja Nimba Taila by Āditya Pāka Taila Vidhi integrates classical Ayurvedic pharmaceutical concepts with contemporary understanding of herbal drug delivery. Although not described as a named formulation in the classical texts, it represents a scientifically rational adaptation based on documented principles of Sneha Kalpana, the traditional methodology of solar-assisted processing, and the established therapeutic properties of Kutaja and Nimba. The formulation should therefore be viewed as a candidate for pharmaceutical standardization and scientific validation, rather than a formulation with already established efficacy. Future investigations should focus on standardized preparation, analytical characterization, stability assessment, pharmacological evaluation, microbiological testing, and well-designed clinical trials to determine its quality, safety, and therapeutic potential Kutaja (*Holarrhena antidysenterica* Wall. ex A.DC.): Classical and Contemporary Perspectives Kutaja (*Holarrhena antidysenterica* Wall. ex A.DC.), belonging to the family Apocynaceae, is one of the most important medicinal plants described in Ayurveda. Although widely recognized for its efficacy in Atisāra (diarrhoea), Pravāhikā (dysentery), and Krimi (helminthic infestations), classical Ayurvedic literature also recommends Kutaja in various Kuṣṭha (skin diseases) owing to its Krimighna (antimicrobial), Kuṣṭhaghna (anti-dermatotic), Kaṇḍughna (anti-pruritic), Śothahara (anti-inflammatory), and Vraṇaśodhana–Vraṇaropaṇa (wound cleansing and wound healing) properties. Modern phytochemical and pharmacological investigations have demonstrated that Kutaja contains a diverse range of biologically active constituents, particularly steroidal alkaloids, which exhibit antimicrobial, anti-inflammatory, antioxidant, immunomodulatory, and wound-healing activities. These properties provide scientific support for its classical indications and justify its inclusion in topical dermatological formulations such as the proposed Kutaja Nimba Taila.

Botanical Description: Kutaja is a small deciduous tree attaining a height of approximately 4–10 m. The bark is greyish-white with irregular fissures. Leaves are opposite, elliptic-oblong, and glabrous. Flowers are white, fragrant, and arranged in terminal corymbose cymes. Fruits are cylindrical follicles containing numerous linear seeds with silky tufts.

Classical Ayurvedic Properties: Ayurvedic classics consistently describe Kutaja as a drug possessing Kashāya (astringent) and Tikta (bitter) taste, with Laghu (light) and Rūkṣa (dry) qualities, Śīta Vīrya (cool potency), and Kaṭu Vipāka (pungent post-digestive effect). It primarily pacifies Kapha and Pitta Doṣa, making it useful in inflammatory and infective conditions.

Classical Therapeutic Indications: Kutaja is extensively mentioned in classical Ayurvedic literature for the management of various disorders.

Phytochemical Constituents: Kutaja contains numerous biologically active phytochemicals that contribute to its pharmacological profile.
Conessine has attracted considerable attention because of its antimicrobial and anti-inflammatory activities.

Dermatological Relevance: The therapeutic profile of Kutaja is particularly relevant for dermatological applications.
Its reported activities include:

- reduction of microbial colonization,

- alleviation of inflammation,
- control of pruritus,
- promotion of wound healing,
- protection against oxidative damage.

These properties provide a pharmacological basis for its inclusion in formulations intended for dandruff, seborrhoeic dermatitis, chronic scalp disorders, and superficial skin infections. However, no published clinical studies have evaluated Kutaja alone or in combination with Nimba Taila as the finished formulation proposed in the present review. Pharmaceutical Relevance in Āditya Pāka Taila Fresh Kutaja leaves constitute the herbal component of the proposed formulation. During Āditya Pāka, gradual exposure to sunlight may facilitate diffusion of phytoconstituents into the lipid medium. Nevertheless, the extent of phytochemical transfer during solar processing has not yet been experimentally quantified.

Future studies employing:

- HPTLC
- HPLC
- GC–MS
- LC–MS/MS

should investigate:

- extraction efficiency,
- phytochemical profile,
- marker compound retention,
- batch-to-batch consistency.

Safety Profile

Kutaja has a long history of therapeutic use in Ayurveda.

Published toxicological studies generally indicate favourable safety when used appropriately.

However:

- the safety of Kutaja Nimba Taila prepared by Āditya Pāka
- dermal irritation profile,
- sensitization potential,
- long-term topical application

remain to be evaluated through standardized preclinical investigations.

Role in the Proposed Formulation

Within the proposed Kutaja Nimba Taila, Kutaja serves as the principal herbal ingredient providing antimicrobial, anti-inflammatory, antioxidant, antipruritic, and wound-healing properties. When combined with Nimba Taila, it is expected to contribute synergistically to the therapeutic profile of the formulation. However, such synergistic effects remain hypothetical until confirmed through pharmaceutical, pharmacological, and clinical studies. Although Kutaja is extensively documented in both classical Ayurvedic literature and modern pharmacological research, most available evidence pertains to individual extracts or isolated constituents. There is currently no direct experimental or clinical evidence evaluating Kutaja Nimba Taila prepared by Āditya Pāka Taila Vidhi. Therefore, therapeutic claims regarding the finished formulation should be considered provisional and require validation through well-designed pharmaceutical studies, preclinical investigations, and randomized controlled clinical trials.

Nimba (*Azadirachta indica* A. Juss.): Classical and Contemporary Perspectives Nimba (*Azadirachta indica* A. Juss.), commonly known as Neem, is one of the most extensively described medicinal plants in Ayurveda and is revered as "Sarva Roga Nivarini" (the curer of all diseases). Belonging to the family Meliaceae, Nimba occupies a prominent position in Ayurvedic therapeutics due to its broad spectrum of biological activities. Classical texts describe it as Kuṣṭhaghna (beneficial in skin diseases), Krimighna (antimicrobial), Kandughna (anti-pruritic), Kledaghna (reducing

excessive moisture), Vraṇaśodhana (wound cleansing), and Vraṇaropaṇa (wound healing). Among the various dosage forms prepared from Nimba, Nimba Taila (Neem oil) is widely employed in Ayurvedic dermatology for the management of dandruff, scalp infections, eczema, psoriasis, chronic wounds, pruritic skin disorders, and other inflammatory dermatological conditions. In the present review, Nimba Taila serves a dual purpose: it functions as the **lipid vehicle (Sneha Dravya)** and also contributes its own pharmacologically active phytoconstituents to the proposed formulation.

Botanical Description; Nimba is a medium- to large-sized evergreen tree attaining a height of 15–20 m. The leaves are alternate, pinnate, and serrated. Flowers are small, white, and fragrant. Fruits are smooth, olive-like drupes containing a single seed rich in fixed oil.

Ayurvedic Pharmacodynamic Properties (Rasapañcaka): Classical Ayurvedic literature consistently describes Nimba as possessing Tikta (bitter) and Kaṣāya (astringent) taste, Laghu (light) and Rūkṣa (dry) qualities, Śīta Vīrya (cool potency), and Kaṭu Vipāka (pungent post-digestive effect). It predominantly alleviates Pitta and Kapha Doṣa, making it particularly valuable in inflammatory and infective skin disorders.

Classical Therapeutic Indications: Nimba is indicated in numerous diseases in classical Ayurvedic texts
These indications strongly support the traditional use of Nimba-based formulations in dermatology.

Phytochemical Constituents: Neem contains a remarkably diverse array of bioactive compounds, many of which have been extensively investigated.These compounds collectively contribute to the biological activities of Nimba Taila.

Pharmaceutical Importance of Nimba Taila: Unlike many herbal oils that function primarily as inert lipid vehicles, Nimba Taila itself possesses substantial therapeutic activity. Consequently, it performs two important pharmaceutical functions:

As Sneha Dravya

- Serves as the lipid medium.
- Facilitates extraction of lipophilic phytoconstituents.
- Improves dermal penetration.
- Enhances stability of the formulation.

As an Active Therapeutic Ingredient

- Contributes antimicrobial activity.
- Provides antifungal action.
- Reduces inflammation.
- Supports wound healing.
- Improves scalp health.

This dual functionality distinguishes Nimba Taila from many conventional pharmaceutical vehicles.

Relevance to Dermatological Disorders

The pharmacological profile of Neem oil closely corresponds with the Ayurvedic indications for skin diseases.
Potential therapeutic applications include:

- dandruff,
- seborrhoeic dermatitis,
- superficial fungal infections,
- eczema,
- psoriasis,

- folliculitis,
- infected wounds,
- chronic pruritus.

However, the efficacy of Kutaja Nimba Taila prepared specifically by Āditya Pāka Taila Vidhi has not yet been evaluated in controlled preclinical or clinical studies. Therefore, these indications should be interpreted as potential applications requiring scientific validation rather than established therapeutic claims.

Safety Profile

Neem has a long history of medicinal use and is generally considered safe when appropriately formulated for topical application.

Nevertheless, certain considerations remain important:

- occasional contact dermatitis,
- hypersensitivity reactions,
- variability in oil composition,
- need for microbial quality assurance,
- requirement for stability assessment.

For the proposed formulation, comprehensive safety evaluation should include:

- dermal irritation studies,
- skin sensitization testing,
- repeated-dose topical toxicity,
- microbiological quality assessment,
- stability studies under recommended storage conditions.

Role in the Proposed Kutaja Nimba Taila

In the proposed formulation, Nimba Taila functions as both the base oil (Sneha Dravya) and an active therapeutic component. During Āditya Pāka processing, it serves as the extraction medium into which phytoconstituents from fresh Kutaja leaves are gradually transferred.

This combination is pharmaceutically rational because:

- Kutaja contributes steroidal alkaloids and other bioactive phytochemicals.
- Nimba Taila provides limonoids, fatty acids, and established dermatological activity.
- The lipid medium enhances topical application and retention.

However, the degree of phytochemical extraction and any synergistic interaction between Kutaja and Nimba remain hypothetical until demonstrated through analytical and pharmacological studies. Nimba is among the best-characterized medicinal plants in Ayurveda and modern phytopharmacology. Extensive evidence supports its antimicrobial, antifungal, anti-inflammatory, antioxidant, and wound-healing properties. Nevertheless, these findings cannot be directly extrapolated to the proposed Kutaja Nimba Taila prepared by Āditya Pāka Taila Vidhi, as the finished formulation has not undergone comprehensive pharmaceutical characterization or clinical evaluation. Accordingly, the proposed formulation should be regarded as a scientifically plausible, classically derived topical preparation requiring systematic standardization, phytochemical fingerprinting, safety assessment, and efficacy evaluation before clinical recommendations can be made. Scientific Rationale for the Proposed Kutaja Nimba Taila Prepared by Āditya Pāka Taila Vidhi The formulation of Kutaja Nimba Taila prepared by Āditya Pāka Taila Vidhi has been conceived by integrating classical Ayurvedic pharmaceutical principles with contemporary scientific understanding of herbal drug delivery. Although numerous medicated oils are described in the Ayurvedic classics, Kutaja Nimba Taila is not described as a named formulation in the available classical literature. The present formulation therefore represents a conceptually derived pharmaceutical preparation, developed by applying the classical methodology of Āditya Pāka Taila Vidhi to two medicinal agents—Kutaja (*Holarrhena antidysenterica*) and Nimba Taila (*Azadirachta indica*)—that possess well-established therapeutic relevance in dermatological disorders.

The formulation has been proposed primarily as a candidate for pharmaceutical standardization, analytical evaluation, and future preclinical and clinical investigation, rather than as an already validated therapeutic product.

Classical Basis for the Formulation

The conceptual basis of the formulation is derived from three established Ayurvedic principles:

- Sneha Kalpana as the pharmaceutical process for preparing medicated oils.
- Āditya Pāka Taila Vidhi as a classical solar-assisted processing technique.
- The documented therapeutic properties of Kutaja and Nimba in Kuṣṭha (skin diseases), Kaṇḍu (pruritus), Krimi (microbial infestations), and Vraṇa (wounds).

Although these principles are individually described in classical texts, their combination into the present formulation is an adaptation based on Ayurvedic pharmaceutical reasoning. This distinction is important to avoid implying that the formulation exists in classical literature as a named preparation. Rationale for Selection of Kutaja: Kutaja was selected because of its classical indications and pharmacological profile relevant to dermatological disorders.

From an Ayurvedic perspective, Kutaja possesses:

- **Kuṣṭhaghna** activity,
- **Krimighna** activity,
- **Kaṇḍughna** action,
- **Śothahara** (anti-inflammatory) properties,
- **Vraṇaśodhana** and **Vraṇaropaṇa** effects.

Modern studies have demonstrated antimicrobial, anti-inflammatory, antioxidant, and wound-healing activities, largely attributed to steroidal alkaloids such as conessine and related phytoconstituents. These findings support its inclusion as the principal herbal ingredient in the proposed formulation.

Rationale for Selection of Nimba Taila

Nimba Taila was selected because it functions both as:

- the Sneha Dravya (base oil), and
- an active therapeutic component.

Neem oil possesses documented antimicrobial, antifungal, anti-inflammatory, antioxidant, and wound-healing properties, making it particularly suitable for topical application in scalp and skin disorders. In addition to serving as the extraction medium during Āditya Pāka, it contributes biologically active limonoids, fatty acids, and other phytochemicals that may complement the activity of Kutaja.

Scientific Basis for Combining Kutaja and Nimba

The combination of Kutaja and Nimba is supported. The complementary actions of the two ingredients provide a rational pharmaceutical basis for their combination. However, any claim of synergistic therapeutic action remains hypothetical until confirmed through experimental studies.

Rationale for Using Āditya Pāka Taila Vidhi

The choice of Āditya Pāka was based on classical pharmaceutical descriptions of solar-assisted processing. Compared with Agni Pāka, Āditya Pāka provides gradual extraction under ambient sunlight without direct heating.

Potential theoretical advantages include:

- gradual diffusion of phytoconstituents,
- avoidance of direct thermal exposure,
- environmentally sustainable processing,
- preservation of formulation integrity through mild processing conditions.

At present, these proposed advantages remain **pharmaceutical hypotheses**, as direct comparative evidence between Agni Pāka and Āditya Pāka preparations of Kutaja Nimba Taila is unavailable.

Proposed Mechanism of Pharmaceutical Processing

The proposed sequence of pharmaceutical events during Āditya Pāka may be summarized as follows:

- Fresh Kutaja leaves are coarsely crushed to increase the exposed surface area.
- The leaves are immersed in Nimba Taila.
- Continuous solar exposure promotes gradual diffusion of phyto constituents into the lipid medium.
- Gentle daily stirring enhances contact between the herbal material and the oil.
- Filtration removes plant residues while retaining the medicated oil.
- The finished product is stored in amber-coloured containers to protect against photo-oxidation.

This mechanism is proposed on the basis of classical pharmaceutical concepts and general extraction principles. It requires validation through analytical studies.

Proposed Standard Operating Procedure (SOP): To improve reproducibility and facilitate future pharmaceutical investigations, the following Standard Operating Procedure (SOP) is proposed. Note: The ingredient ratio and processing duration proposed above are based on classical Āditya Pāka principles and pharmaceutical reasoning. They should be optimized and validated through future pharmaceutical studies.

Recommended Quality Control Measures: Each batch of Kutaja Nimba Taila should undergo comprehensive quality assessment before clinical application. The analytical techniques listed above are recommended for future standardization and were not performed as part of the present narrative review.

Limitations of the Proposed Formulation

Despite its strong classical and pharmaceutical rationale, several limitations should be acknowledged:

- The formulation is **not described as a named preparation in classical texts**.
- There are **no published preclinical or clinical studies** evaluating the finished formulation.
- The proposed SOP has not yet undergone pharmaceutical validation.
- The phytochemical profile after Āditya Pāka has not been characterized.
- Comparative studies with Agni Pāka preparations are lacking.

Therefore, the present formulation should be regarded as **a** scientifically plausible candidate for future investigation rather than an established therapeutic intervention. Kutaja Nimba Taila prepared by Āditya Pāka Taila Vidhi represents a pharmaceutically rational adaptation of classical Ayurvedic principles. The formulation integrates the established therapeutic attributes of Kutaja and Nimba with the traditional concept of solar-assisted processing. While the theoretical rationale is supported by classical literature and modern pharmacological knowledge of the individual ingredients, the finished formulation itself remains insufficiently studied. Future work should prioritize pharmaceutical standardization, phytochemical characterization, quality control, pharmacological validation, and randomized clinical trials to establish its safety, efficacy, and role in evidence-based Ayurvedic dermatology.

Table 1: Comparative Features of Agni Pāka and Āditya Pāka

Parameter	Agni Pāka	Āditya Pāka
Source of heat	Direct fire	Natural sunlight
Processing temperature	High	Mild to moderate ambient temperature
Processing duration	Hours	Several days

Energy source	Conventional fuel	Solar energy
Extraction pattern	Rapid	Gradual
Suitability	Internal and external formulations	Primarily topical formulations
Standardization	Well established	Requires further validation
Scientific evidence	Extensive	Limited

Table 2: Key Features of Āditya Pāka Taila Vidhi

Feature	Description
Pharmaceutical basis	Solar-assisted processing of medicated oils
Classical status	Described as a pharmaceutical technique; not specific to Kutaja Nimba Taila
Processing medium	Natural sunlight
Heating method	No direct fire
Present evidence	Primarily classical descriptions and theoretical rationale
Major limitation	Lack of comparative scientific studies
Future requirement	SOP development, analytical standardization, pharmacological and clinical validation

Table 3: Botanical Profile of Kutaja

Parameter	Description
Botanical name	*Holarrhena antidysenterica* Wall. ex A.DC.
Family	Apocynaceae
Sanskrit names	Kutaja, Vatsaka, Girimallika, Indravriksha
English name	Kurchi Tree, Conessi Tree
Hindi	Kutaj
Kannada	Kodasige
Parts used	Bark, leaves, seeds, flowers
Distribution	Throughout India, especially sub-Himalayan regions, deciduous forests, and tropical climates

Table 4: Classical Therapeutic Uses

Disease	Ayurvedic Action
Atisāra	Grahī, Stambhana
Pravāhikā	Antidiarrhoeal
Krimi	Krimighna
Kuṣṭha	Kuṣṭhaghna
Kaṇḍu	Kaṇḍughna
Vraṇa	Vraṇaśodhana, Vraṇaropaṇa
Rakta Duṣṭi	Rakta Prasādana
Jvara	Jvaraghna

Table 5: Major Phytochemical Constituents of Kutaja

Class	Important Constituents
Steroidal alkaloids	Conessine, Holarrhenine, Holarrhimine, Kurchicine
Flavonoids	Quercetin derivatives
Phenolics	Gallic acid derivatives
Tannins	Condensed tannins
Terpenoids	Various triterpenoids
Sterols	β-sitosterol

Table 6: Pharmaceutical Significance of Kutaja in the Proposed Formulation

Characteristic	Pharmaceutical Relevance
Classical indication	Kuṣṭha, Kaṇḍu, Vraṇa
Principal phytochemicals	Steroidal alkaloids
Major pharmacological actions	Antimicrobial, anti-inflammatory, antioxidant
Pharmaceutical role	Herbal source of active constituents
Present evidence	Supported for the individual plant; not for the finished formulation
Future requirement	Standardization, analytical profiling, efficacy and safety evaluation

Table 7: Botanical Profile of Nimba

Parameter	Description
Botanical name	*Azadirachta indica* A. Juss.
Family	Meliaceae
Sanskrit names	Nimba, Arishta, Pichumarda, Prabhadra
English name	Neem
Hindi	Neem
Kannada	Bevu
Parts used	Leaves, bark, seeds, flowers, fruits, root, oil
Distribution	Throughout tropical and subtropical India and many tropical countries

Table 8: Classical Indications of Nimba

Disease	Classical Action
Kuṣṭha	Kuṣṭhaghna
Kaṇḍu	Kandughna
Krimi	Krimighna
Vraṇa	Vraṇaśodhana, Vraṇaropaṇa
Prameha	Pramehaghna
Jvara	Jvaraghna
Rakta Duṣṭi	Raktaprasādana
Visarpa	Viṣarpaghna

Table 9: Major Phytochemicals of Nimba

Class	Important Constituents
Limonoids	Azadirachtin, Nimbin, Nimbidin
Terpenoids	Gedunin, Nimbolide
Flavonoids	Quercetin
Polyphenols	Gallic acid derivatives
Sterols	β-Sitosterol
Fatty acids	Oleic, Stearic, Palmitic, Linoleic acids

Table 10: Pharmaceutical Role of Nimba Taila in the Proposed Formulation

Pharmaceutical Property	Significance
Sneha Dravya	Lipid extraction medium
Active ingredient	Antimicrobial and anti-inflammatory activity
Skin penetration	Facilitates topical drug delivery
Stability	Protects lipid-soluble phytoconstituents
Dermatological application	Suitable for scalp and skin disorders
Present evidence	Strong for Neem individually; lacking for the combined formulation

Table 11: Comparative Therapeutic Contributions of Kutaja and Nimba

Parameter	Kutaja	Nimba Taila
Principal role	Herbal drug	Base oil and active ingredient
Major phytochemicals	Steroidal alkaloids	Limonoids, terpenoids, fatty acids
Antimicrobial activity	Yes	Yes
Anti-inflammatory activity	Yes	Yes
Antioxidant activity	Yes	Yes
Wound-healing activity	Yes	Yes
Lipid vehicle	No	Yes
Traditional dermatological use	Yes	Yes

Table 12: Proposed SOP for Kutaja Nimba Taila Prepared by Āditya Pāka Taila Vidhi

Step	Procedure
Ingredients	Nimba Taila (1 part); Fresh Kutaja leaves (1 part, coarsely crushed)
Selection of Raw Materials	Collect healthy, disease-free leaves; authenticate botanical identity.
Cleaning	Wash with potable water and shade-dry to remove surface moisture.
Preparation	Coarsely crush the leaves and transfer them into a clean, dry, wide-mouthed glass container. Add the measured quantity of Nimba Taila and mix thoroughly.
Solar Processing	Cover with sterile muslin cloth or a breathable lid. Expose to direct sunlight for approximately **6–8 hours daily** for **7 consecutive days** (or until adequate extraction is achieved). Stir gently **2–3 times daily** using a sterile glass rod. Bring the container indoors after sunset and protect it from rain, dust, insects, and excess humidity.
Filtration	Filter through sterile muslin cloth or Whatman filter paper.
Packaging	Transfer to sterile amber glass bottles and seal immediately.
Storage	Store in a cool, dry place away from direct sunlight. Label with batch number and preparation date.

Table 13: Recommended Quality Control Parameters

Category	Parameters
Organoleptic	Colour, odour, appearance, consistency
Physicochemical	Specific gravity, refractive index, viscosity, acid value, peroxide value, iodine value, saponification value, moisture content, rancidity
Phytochemical	Qualitative and quantitative estimation of alkaloids, flavonoids, phenolics, tannins, terpenoids, glycosides; HPTLC, HPLC, and GC–MS fingerprinting
Microbiological	Total aerobic microbial count, total fungal count, absence of specified pathogens
Stability	Accelerated and long-term stability studies, shelf-life determination

ABSTRACT

One of the critical unknowns in clinical pharmacology is the ability of different people to respond to a drug in different ways. Although substantial amounts of variation in drug responses have been deciphered, from an estimated 20-40%, the role played by the gut microbiome has become an increasingly important, but largely unexplored, variable impacting on the pharmacokinetics (PK) of orally delivered drugs. Microbiota can have an impact on the absorption, distribution and metabolism of a drug through 4 simultaneous mechanisms: it can regulate the expression of intestinal drug transporters by effecting expression or production of microbial metabolites in the intestine; it can alter the composition of the bile acid pool that regulates the induction of hepatic drug metabolizing enzymes and drug transporters through nuclear receptors; it can directly modulate hepatic cytochrome P450 activity through the gut-liver axis; and it can directly biotransform drugs in the gastrointestinal tract. All these mechanisms are also affected by gut dysbiosis (the disease associated structural alteration of the microbial community) which can result in the loss of microbial diversity, a reduction in amounts of producer taxa of short-chain fatty acid (SCFA), and a rise of taxa of pathobionts, with important clinical consequences for therapy with narrow therapeutic windows (NTWs) like that of tacrolimus, irinotecan and digoxin. Here it provides a detailed, understanding of the mechanistic pathway from dysbiosis to changes in PK; a systematic review of dysbiosis-related changes in pg clinical trials; a consideration of strategies for restoring the microbiome across all drug classes; and a logical evolution and discussion of six key areas of research needed, including the need for validated dysbiosis severity PK biomarkers, uncharacterised PK basis of

antidepressant non-responsivity, and a lack of microbiome parameters in pg models. The answers to these omissions are essential for the inclusion of pharmaco-microbiomics in suitable pipeline of precision medicine and for the well-being of patients when exposed to the unknown risks of patients' GIX.

Keywords: gut microbiota; pharmacomicrobiomics; gut dysbiosis; pharmacokinetics; drug transporters; P-glycoprotein; bile acids; short-chain fatty acids; CYP3A4; tacrolimus; irinotecan; digoxin; SSRI; enterohepatic recycling

INTRODUCTION

The response to a drug is highly individual and to this day one of the most clinically relevant and mechanistically complicated problems in pharmacology. The field involved in the effect of oral pharmacology on the oral or gut microbiome as well as the effect of the oral or gut microbiome on the oral pharmacology is termed the 'pharmacomicrobiomics' and there are human clinical applications for nearly all drug classes given orally. The pharmacokinetics of drugs can be directly and indirectly impacted by the microbiota. Microbial metabolites, most importantly short chain fatty acid metabolites (SCFAs), secondary bile acid metabolites, and indole metabolites (derived from the amino acid tryptophan) are all members of a group of signalling molecules that can activate the gut receptors for example (prenegnane X receptor (PXR), farnesoid X receptor (FXR), aryl hydrocarbon receptor (AhR)), which then regulate the expression and activity of intestinal drug transporters and hepatic cytochrome P450 (CYP) enzymes in the intestine and/or in the liver, either directly or indirectly, resulting on pyroprodrugs that are metabolized to drugs, detoxification of therapeutic agents or metabolite reactivation [1, 2]. Although the mechanisms are becoming more familiar, none of the existing pharmacokinetic modeling framework, dose adjustment algorithm or regulatory drug development guideline includes gut microbiome parameters directly, thus raising patient safety concerns. This review aims to make mechanistical and clinical evidence a whole in a common set-up or framework of a medicine. We first systematically review the 4 possible mechanisms by which dysbiosis might alter oral drug pharmacokinetic parameters, and then explore the oral drug pharmacokinetic parameters as they relate to different disease contexts, including the five key classes wherein there is documented clinical evidence. Then pharmacologic strategies which have been proposed to restore microbiome-mediated PK normalisation are explored and six major gaps in research that must be resolved in order to advance pharmacomicrobiomics to the clinical arena are discussed [5, 6, 7].

Gut Microbiome and Dysbiosis: Pharmacologically Relevant Concepts

Composition under Homeostasis

The Firmicutes species F. prausnitzii, R. intestinalis and B. fibrisulvens, as well as the Bacteroidetes species P. acnes, produce pharmacologically important microbial metabolites such as the so-called short-chain fatty acids (SCFAs) butyrate, propionate and acetate, however, secondary bile acids are produced by the Clostridiales species with BSH activity, and indoles by the activity of Lactobacillus spp. and Clostridium spp. These gut microbial metabolites need to be physiologically produced to maintain homeostatic regulation of intestinal epithelial integrity, to modulate the expression of drug transporters and expression levels of nuclear receptor signalling pathways that drive drug-metabolising enzyme (DME) induction [8].

Defining Dysbiosis

The dysbiosis profile associated with each disease state has a distinct composition of dysbiotic microbes, with pharmacologically specific consequences: IBD-associated dysbiosis is characterised by depleted levels of the Firmicutes, F. prausnitzii and Roseburia, but enriched levels of the potentially-adherent and-pathogenic species, AEC (or adherent-invasive Escherichia coli), which have drug-inactivating enzymatic activity, as well as decreased availability of commensal protective microbes such as SCFA-producing Firmicutes, and decreased levels of

azoreductase, an enzyme critical for the activation of 5-ASA prodrugs; obesity and T2D dysbiosis involves reduced levels of the Firmicutes, Akkermansia muciniphila and Bifidobacterium, and increased levels of the F. genus, Fusobacterium and Proteobacteria, with an especially high F/B ratio, which affects bile acid homeostasis and handling of the anti-hyperglycemic drug, metformin; dysbiosis in MDD involves decreased SCFAs-producing Firmicutes, increased adherent and-pathogenic E. coli (e.g., AEC) and an increased abundance of E. lenta, a Firmicutes sp. with known drug-inactivating enzymatic activity.

Effect on pharmacologically active microbial enzymes

The gut microbiota blockly displays a wide spectrum of drug-metabolising enzymes that lack within the human genome but whose activity can significantly influence drug pharmacokinetics. Of direct clinical relevance, the cardiac glycoside reductase (cgr) operon, consisting of two genes that encode enzymes capable of reducing the cardiotonic drug digoxin to pharmacologically inactive dihydrodigoxin, is found in Eggerthella lenta. Pharmacokonjugation and deconjugation, mediated by multiple taxa including Clostridiales, Bacteroides and Escherichia coli, are relevant to the deconjugation of glucuronide metabolites of drugs in the intestinal lumen, liberating the parent compound for reabsorption and thereby increasing systemic drug exposure and toxicity; a process that may be directly relevant to irinotecan, NSAIDs and mycophenolate. BSH enzymes can modify the pool of bile acids that are active in the intestine, affecting the activity of the nuclear receptors FXR, TGR5 and PXR and hence downstream transporter and CYP enzyme expression in the intestinal epithelium and liver [20, 21].

Mechanisms: Dysbiosis and Altered Drug Absorption

Drug Transporter Regulation by Microbial Metabolites:

The major gatekeepers of oral drug bioavailability are intestinal transporters, such as ATP-binding cassette (ABC) efflux transporters P-glycoprotein (P-gp/ABCB1), breast cancer resistance protein (BCRP/ABCG2) and multidrug resistance-associated protein 2 (MRP2/ABCC2), as well as solute carrier (SLC) influx transporters OATP1A2 and OATP2B1, all of which are highly regulated by gut microbial metabolites via nuclear receptors, transcriptions and post-translational mechanisms on expression levels.[8,9] Here, microbial control of baseline intestinal P-gp , which regulates the transport of P-gp substrate drugs, was shown to depend on microbiota comprehensiveness and is enhanced by the col types firmicute Clostridia and bacille Bacilli through epigenetic mechanisms involving P-gp-inhibiting HDAC without any specific dependence on any single col type, thereby confirming the ARI that defines intestinal P-gp function and the microbiota's role is dictated by microbial core integrity, not individual col types [8, 22]. The metabolites of indole-producing Lactobacillus species activate the aryl hydrocarbon receptor (AhR) in intestinal epithelial cells, which also has a direct pharmacological effect on the OATP-mediated influx transport of absorbed substances, and the metabolites of Eggerthella lenta inhibit P-gp ATPase activity in a post-translational manner that so far did not involve OATP transportin [8,9].

Bile Acid Pool Dysregulation and Drug Solubilisation:

Secondary bile acids activate FXR in the intestinal epithelial cells, which then suppresses the activity of CYP7A1 (the enzyme responsible for cholesterol to bile acid conversion), while also inducing FXR-mediated expression of other gene downstream of the FXR-responses elements on the promoters of the drug transporter OSTα/β and the efflux pump p-gp (in a manner that depends on the composition of the dysbiotic bile acid pool). [18, 19] Depletion of taxa which express BSH in the dysbiotic gut microbiota will lead to accumulation of primary conjugated bile acid and also a reduction in the levels of secondary bile acids, which in turn have been shown to inhibit the ATPase activity of p-gp and alter the multidrug resistance efflux landscape, depending on their hydroxyl organization.

Master PK-regulators: SHORT CHAIN FATTY ACIDS Master:

The effects of SCFAs on P-gp expression aren't the only that are mediated by the paracellular route. Butyrate also upregulates tight junction proteins that restrict non-specific passive entry of small molecules; when the production of butyrate is depleted, as is seen during dysbiosis, tight junction proteins become downregulated, allowing more

passive paracellular entry of small molecules and increasing systemic exposure to those that rely heavily on paracellular restriction for their absorption.Beyond the effects of the SCFAs on P-gp expression, butyrate has broad pharmacokinetics effects, as well: It has been shown to induce expression of the tight junction proteins that regulate non-specific passive absorption, which means that when its production is depleted, as seen during dysbiosis, delays food transit in the gut, leading to more passive absorption into the systemic circulation of orally administered drugs that rely on tight paracellular restriction for absorptive success [26,28].

Enterohepatic Recycling Amplification by β-glucuronidase:

The SN-38 metabolite from irinotecan is variously glucuronidated and excreted into the bile and is then re-conjugated by microbial enzymes in the gut. This is known as Enterohepatic recycling (EHC) and has been shown to enhance exposure, systemic toxicity and clearance of the parent drug by amplification of the microbial enzyme activity, depending on the compound and slight changes in bowel flora or bacterial expression [6,29]. After drug Glucuronidation in the liver and biliary excretion, there is the potential for Enterohepatic recycling (EHC), the re-excretion of hepaticly excreted drug metabolites, after the bacterial deglucuronidation to regenerate the parent compound and/or its toxic aglycone forming the toxicological burden. Selectivity and specificity in pharmacological inhibition of the bacterial enzyme is an established proof of concept with drugs such as inh-1, which results in the reduction of intestinal SN-38 re-enunciation from irinotecan glucuronide together with a pharmacokinetics effect without influencing serum serum irinotecan or glucuronide concentrations [32].

Mechanisms: Dysbiosis and Hepatic/Systemic Drug Metabolism

The Gut-Liver Axis and Microbial Modulation of Hepatic CYPs:

All 76,000 conventional germ-free mice (genotobiotic) studied have liver CYP3A expression, which is significantly reduced compared to conventional germ-positive mice, providing an example of one of the critical ways in which the liver controls gut expression of CYP enzymes, which clearly demonstrates that the gut microbiome is required for the upregulation of basal liver CYP3A activity. Increased systemic bioavailability of CYP3A4 substrates (such as tacrolimus, midazolam, cyclosporine and some statins) in dysbiosis also leads to reduced hepatic first-pass metabolism due to the inflammatory suppression of the PXR-CYP3A4 axis, which can be clinically complicated by pharmacogenomic CYP3A5 non-expressor phenotype, and can result in a longer half-life of these drugs.[35,36]

Direct Microbial Drug Biotransformation in the Intestinal Lumen:

In addition to interacting indirectly with host enzyme systems, our gut bacteria metabolise drugs within their intestinal lumen, by enzymatically converting the parent compound to active, inactive or toxic metabolites, depending on the specific drug and gastro-intestinal microorganism involved. Klünemann et al. showed that 76 of the 197 clinically approved non-antibiotic drugs are actively imported into the cell by gut bacteria, potentially sequestering the drug and in turn affecting its availability to the gut epithelia that interface the intestinal lumen with the circulation. The aggregate metabolism and drug-bioaccumulation capacity of the gut microbial community — a PK compartment that is not currently represented by any existing pharmacokinetic model — is altered by dysbiosis and the quantitative clinical significance of these effects remain undefined.[7,22,37,38]

Dysbiosis produced systemic inflammation and modulation of cyp activity:

This observation of pharmacokinetic alterations already has been demonstrated to occur in acute infections and states of inflammation, but the underlying mechanisms are not only cytokines, but also activity of pattern recognition receptors that lead to microbial translocation and subsequently to elevated levels of cytokines, such as IL-6 and TNF-α, which directly depress the expression of several CYP-isoforms in hepatocytes by post-transcriptional and transcriptional mechanisms. During acute infections and inflammatory episodes, this phenomenon of CYP suppression has been attributed to the action of the cytokines; however, in dysbiosis, where microbial translocation occurs and pattern recognition receptor activation takes place, the underlying mechanism has received marginal

interest in clinical pharmacology and represents a research gap with clinical implication regarding patient safety for therapeutic drug monitoring [13, 35].

Disease-Specific Dysbiosis and Drug Pharmacokinetics: Clinical Evidence by Drug Class

The mechanistic framework established in Sections 3 and 4 manifests as clinically distinct pharmacokinetic consequences across disease-associated dysbiosis states. The following analysis provides a disease-stratified synthesis of drug-class-specific PK evidence — an integrated comparative framework that does not currently exist in the review literature [5, 13].

IBD Dysbiosis and 5-ASA / Immunosuppressant PK:

The microbially atypical balance of beneficial gut bacteria and harmful bacteria is highlighted by the Kozhemyako signature in IBD and the documented microbiome variation and widely observed PK differences in response to the core drug tacrolimus in both IBD and post-transplant settings [17,35]. The same effect of the gut microbiota on the PK of tacrolimus has been demonstrated in a pilot cross-sectional study with 93 kidney transplanted patients that did not express CYP3A5, which found that diverse gut microbes were strongly associated with decreased intraindividual AUC variability in tacrolimus, and that SCFA-producing taxa such as Blautia and Roseburia were inversely correlated with tacrolimus dose requirement suggesting a protective effect of SCFAs on reduction of tacrolimus efflux, thereby increasing absorption across the intestine.[41]

Obesity/T2D Dysbiosis & Metformin/Statin PK:

Statins have both PK and PD effects from the microbiome: statins are highly absorbed in the gut microbiome, and there is increased evidence that the microbiome has a clinically meaningful role in increasing the pharmacodynamic variability of statins, with some studies revealing the ability to predict the statin drug response based on microbial composition rather than genetic variation in drug transporters. [42] In some antibiotic-treated rats colonised with dysbiotic microbiota, losartan bioavailability is significantly decreased and the prevalence of dysbiosis in a large cohort of patients treated with statins is association with decreased bioavailability. This suggests there is a bidirectional relationship between the drug and the microbiome: statin therapy alters dysbiosis prevalence whereas dysbiosis alters statin bioavailability.

Cancer Dysbiosis and chemotherapy PK:

Irinotecan, also known as CPT-11, is a paradigm drug that is made tumouricidal by amplification in its enterohepatic-micobiome pathway. Finally, a pharmacodynamic interaction, in which the abundance of the taxa Akkermansia muciniphila, Faecalibacterium prausnitzii and Bifidobacterium at baseline has been consistently associated with improved objective response rates and survival in multiple independent cohorts of anti-PD-1/anti-CTLA-4-treated patients, contrasts with pharmacokinetically mediated interactions, where bacterial metabolism of the drug happens in the gut and contributes to the dose-limiting diarrhoea and gastrointestinal mucosal injury of irinotecan treatment. Microbiome-drug interactions are not limited to gut-related interactions and encompass many other mechanisms, such as inactivation of Gemcitabine by cytidine deaminase expressed by intratumoral bacteria, especially by Mycoplasma spp. and gram-positive bacteria [46, 47].

MDD Dysbiosis and SSRI Pharmacokinetics:

While dysbiosis is associated with a distinct element of MDD, with an elevated abundance of Alistipes and Eggerthella, and reduced abundance of Lactobacillus and Bifidobacterium, and reductions in SCFA production, the single largest unaddressed research gap remains a study of the pharmacomicrobiome of an SSRI drug. This is because there is no systematic study on the pharmacokinetics of SSRIs in relation to MDD-associated dysbiosis, which encompass reductions in intraluminal serotonin substrate availability upon which the pharmacological effects of SSRIs depend, and modifications of P-gp-dependent intestinal absorption, though mapping this interactions is highly relevant, and alterations in the production and metabolism of drugs in the liver under the regulation of enteroluminal axis cytokines [50].

Tacrolimus and PK in transplants:

Tacrolimus is the most well-studied narrow therapeutic index drug in pharmacomicrobiomics. The mechanism involved is the dual pathway whereby changes in microbiome leads to decreases in both intestinal expression of ABCB1 and decrease in hepatic expression of CYP3A4 in a NF-κB/ PXR-dependent manner, resulting in increased intestinal absorption and reduction in hepatic clearance of tacrolimus, respectively, which may also contribute to increases in tacrolimus PcV.Genomic dysbiosis involves a dual mechanism: namely, decreases in intestinal expression of ABCB1, which increases absorption; and decreases in hepatic expression of CYP3A4, which is mediated by NF-kB/ PXR-mediated repression of hepatic expression, which may also contribute to tacrolimus PcV increases [51].

Pharmacological Strategies to Restore Microbiome and Normalise Drug PK

Probiotics and SCFAs as PK Modulators:

Oral supplementation of probiotics containing SCFA-producing bacteria, such as lactobacilli (Lactobacillus spp.), which more mechanistically relevantly restore intestine expression of claudin-1 and occludin, as well as intestine expression deficits that are caused by PXR mediated expression markers for metabolisation, such as CYP3A4/upregulated background, restores these deficits, supports the Pharmacokinetically Rationale Drug Absorption Minimisation and stands as an active transporter-mediated efflux restoration approach in the setting of dysbiosis: to date, butyrate is directly available; supplementation with probiotics with a butyrate-releasing effect, such as taxa of lactobacilli (Lactobacillus spp.), is directly available; to date, there are no reports of butyrate having an anti-inflammatory effect in the intestine; the epigenetic effect of butyrate on the expression of PXR-regulated drug transporters, such as CYPs 3A4/upregulated background, has been described; to date, no other probiotics can have such a direct pharmacologic effect on PXR as supplemented by butyrate that also inhibits HDACs [26, 53].

Fecal Microbiota Transplantation

In humans, the first narrow therapeutic index drug reported to be benefitted by microbiome restoration with FMT was via improvement in the efficiency of the prodrug activation of sulfasalazine after FMT in antibiotic-pretreated animals that lack azoreductase activity. In the literature, there have been no clinical studies of how the activation of the sulfasalazine prodrug impacts the efficacy of the microbiome's activation, and this will need to be studied in humans with dysbiotic microbiomes, like in patients with C. diff and antibiotic-associated diarrhea (AAD).Recently, FMT has been shown to restore azoreductase activity in antibiotic-treated animals, reviving the efficiency of activation of sulfasalazine, a prodrug with a narrow therapeutic index, which has yet to be proven and should be reported in the literature [55].

Inhibitors of microorganisms specifically:

Dietary supplementation by arginine increases bioavailability to bacterial species considered to be non-digoxin susceptible, while diminishing the toxicity to all E. coli species, explaining a selective pathway of drug detox, suggesting that targeting specific bacterial enzymes can provide a means to overcome low system levels of any drug in human patients caused by unanticipated overcolonisation of the gut by the pathogenic strain. The use of the amino acid arginine has proven to selectively intervene with the transcription of the cgr operon, increasing digoxin bioavailability in both uncolonised samples and when grown in the presence of other bacteria species, but decreasing the toxicity of digoxin in the species E. lenta [21, 32].

Research Gaps, Challenges, and Future Directions

The ongoing evidence and mechanisms presented in this review highlight dysbiosis in the gut as a pharmacologically significant, clinically relevant, and less-controlled factor determining oral drug pharmacokinetics. Yet important basic knowledge gaps exist which have hindered translation for this knowledge to clinical practice [5,13].

Gap 1: Identification of a clinical PK Biomarker for severity of dysbiosis:
Previous pK studies in dysbiosis-associated disease cohorts have been conducted in an exploratory fashion and not included a dysbiosis marker in conjunction with a therapeutic drug biomarker that can be correlated to measure PK perturbation of specific drug-exposure measures such as AUC, Cmax or trough concentrations — a key step in the qualification of a biomarker for a prospective study. Stereotypically, a PGX signature was collected and an exploratory correlation analysis was performed as an afterthought, and validation markers were collected and assessed in retrospective samples. Future PK studies of dysbiosis-associated diseases should validate the biomarkers of these specific diseases together with the standard therapeutic drug monitoring assessment parameters in prospective studies to enable a correlation analysis that helps qualify the biomarker for the drug-exposure measure (AUC, Cmax, trough) to be used in future studies as a surrogate for clinicobiologic endpoints [56].

Gap 2: SSRI Pharmacokinetics and Gut Dysbiosis — Mechanistic Characterisation Absent:
Finally, future studies will need to systematically determine whether there are measurable PK differences (e.g. lesser Cmax, AUC and half-life) in non-responders compared to responders in MDD, matched on CYP2D6/CYP2C19 genotype, and whether these differ from one marker of dysbiosis to another (e.g. depletion of SCFAs, increase in the abundance of Eggerthella, decrease in intestinal P-gp expression).[49,50]

Gap 3: Microbiome Exclusion from PBPK Modelling Frameworks:
There is now sufficient mechanistic data to enable the integration of a microbiome module into PBPK models for drugs that predict the microbiome-mediated alteration of drug PK, such as physiologically-based relationships between the oral microbiome and SCFA-P-gp, bile acid-FXR-CYP3A4, and β-glucuronidase-EHC amplification.Regulatory agencies (e.g., FDA and EMA) should be engaged to establish standards for the collection of microbiome data in drug development programmes targeting the microbiome pathway that influences oral bioavailability of drug substrates, such as ABCB1 (SRB)-P-gp; ABCG2 (NSAID)-FXR-CYP3A4; and β-glucuronidase-EHC, which is the drug-microbiome interaction space of most clinical significance [57].

Gap 4: Clinical Scale and PK Consequences of Drug Bioaccumulation in Bacteria:
The extent of drug bioaccumulation in human pharmacokinetic studies is not known, as is the quantitative impact of dysbiosis — the alteration of the bacterial biomass, species composition, and/or transporters expression — on the degree of drug bioaccumulation in the gut bacterial community (in a clinically relevant manner) is unknown[37,38].

Gap 5: Sex and Age as Confounders in Pharmacomicrobiomics Research:
Sex and age are two new variables in study design that should be analyzed as primary variables on the basis of their influence on microbiome composition and how they impact PK variability; to date, a majority of pharmacomicrobiomics studies only treats these variables as demographic descriptors. Microbiome composition is significantly different between males and females due to sex hormones regulating microbial diversity and metabolite production, and to the significant microbial compositional differences in paediatric, adult, and geriatric patients, who differ in their microbiomes composition and enzymatic activity. Sex and age should therefore be considered as pharmacomicrobiomic confounders and treated as main study variables as opposed to demographic descriptors [58].

Gap 6: Effects of Antibiotic-Associated Disruption of Enteric Flora and Non-Antibiotic Drug Pharmacodynamics
Clinical studies have demonstrated changes in blood-level results for therapeutic drugs given with antibiotics, but there remains a need for more systematic characterisation of the classes of therapeutic drugs that are affected by antibiotic-induced dysbiosis, the duration of effect in blood-level results post antibiotic course, the extent and rapidity of microbiome-recovery, and the community's understanding of how these changes impact drug safety in hospitalised patients receiving broad-spectrum antibiotic therapy who are also receiving therapeutic drug monitoring [59, 36].

CONCLUSION

Each of these four mechanistically distinct and interacting pathways is disrupted during gut dysbiosis in disease and would be expected to be distorted during the disease process for narrow therapeutic index (NTI) drugs, such as tacrolimus, irinotecan, digoxin, levodopa, and sulfasalazine — drugs whose pharmacological activity is significantly influenced by the gut microbiota — as described (but not documented) clinically. [39,29,39,21,17] Absence of validated PK biomarker(s) of dysbiosis, uncharacterised SSRI PK-microbiomic interaction(s) exposition, failure to incorporate microbiome in PBPK models, undefined clinical scale of antibiotic-PK interaction(s) in bacteria, systematic sex and age confounding, and uncharacterised antibiotic-PK interaction(s) duration are the six research gap(s) highlighted in this review as the most important needs to move this field from discovery to clinical translation.The six research gaps identified in this review — absence of validated PK biomarker(s) of dysbiosis, uncharacterised SSRI PK-microbiome interaction(s) exposition, failure to incorporate microbiome in PBPK models, undefined clinical scale of drug bioaccumulation in bacteria, systematic sex and age confounding, and uncharacterised antibiotic-PK interaction(s) duration — are key in advancing this field from discovery to clinical translation [13, 49, 57]. This will be made possible via prospective studies that allow co-collection of validated microbiome data, and by sex stratification as a standard methodology element; regulatory cooperation to add microbiome parameters into drug development programmes; and the development of a gut microbiome module within next generation PBPK modelling frameworks. Pharmacomicrobiomics will become an integral part of precision pharmacology, not as a substitute for pharmacogenomics, but as a similarly important and easily modifiable factor of individual drug response that can be measured, monitored, and therapeutically changed on the fly — a change that unlike the genome can be performed in real time.

ABSTRACT

Volleyball is a dynamic sport that demands quickness, agility, explosive power, muscular endurance, and flexibility. There are a range of fitness exams, but there is no universal and proven physical fitness-testing battery designed for teenage volleyball players. Thus, the formulation of an evidence-based assessment tool is necessary for the identification of talent, the evaluation of athletes, and the design of training programmes. To develop, validate, and standardize a well-rounded physical fitness test battery for the evaluation of adolescents who engage in volleyball matches, in addition to establishing normative standards for conducting performance evaluations. A total of 550 adolescent volleyball players aged 13-18 years were recruited out of different districts of Tamil Nadu. Potential test items were identified through extensive literature review and expert consultation between Directors of Physical Education, professors of volleyball, volleyball coaches; Sports Authority of India (SAI) coaches; Sports Development Authority of Tamil Nadu (SDAT) coaches; experienced players. The selected tests evaluated validity, reliability, and objectivity. Interrelationships between variables were determined by Pearson Product Moment Correlation. Principal Component Analysis (PCA) was then followed by Varimax Rotation of the variables to identify the underlying factors. Representative tests for the final battery were selected according to factor loadings. Then percentile and T-score norms were created. The assessment from experts placed speed, agility, explosive power, muscular endurance and flexibility as the most important physical fitness factors for performance in volleyball. Reliability coefficients ranged from 0.87 to 0.94,

while objectivity coefficients ranged from 0.89 to 0.96. The Kaiser-Meyer-Olkin value (0.864) and significant Bartlett's Test of Sphericity confirmed that the data was suitable for factor analysis. Five factors corresponding to the selected physical fitness components were extracted. They account for approximately 95% of the total variance. The final test battery was comprised of: 50-Meter Sprint Test, Shuttle Run Test, Vertical Jump Test, Bent-Knee Sit-Up Test and Sit-and-Reach Test. Percentile and T-score scales were used for the development of normative criteria. The physical fitness test battery was reliable, valid, objective and the test battery which was developed proved useful for evaluating adolescent volleyball athletes. The battery offers a standardized method to determine talent, player selection, performance assessment, & long term development of athletes. The normative criteria in the study serve as valuable reference points for coaches, physical teachers and sports scientists.

Keywords: Volleyball, Adolescent Players, Physical Fitness, Test Battery, Validation, Standardization, Talent Identification.

INTRODUCTION

Volleyball game is fast moving and incorporates both explosive actions and sudden turnarounds, repeated jumps, and sustained physical movement from start to finish of the game. Much of the success in volleyball hinges on the player's ability to perform these movements efficiently and consistently. Thus, the evaluation of components of physical fitness today is crucial for the identification of talent, selection of players, prescription of training, and assessment of performance (Sheppard, Gabbett & Stanganelli, 2009). Adolescence is an important stage of sports development, when a lot of physical, physiological, and neuromuscular changes take place. Athletes are going through rapid growth and maturation with tremendous implications for their athletic performance. Therefore, the identification and assessment of adolescent physical fitness characteristics is vital for developing future elite volleyball players. It becomes crucial that coaches and athletic scientists adopt tools with a scientific background which can evaluate the physical capabilities of young athletes and monitor progress in a systematic manner (Malina, Bouchard & Bar-Or, 2004).

Among all the physical fitness elements that influence volleyball performance, it was obvious time and time again that speed, agility, explosive power, muscular endurance, and flexibility are vital to success in this sport. Speed allows players the ability to move quickly through the court in different areas and react quickly to things during a game. Agility enables change of direction and good body control in offensive and defensive moves. It is only with strong explosive power and muscular endurance you can carry out spikes, blocks, and jump serves in a sprint, but the same muscular endurance means that you can maintain high-intensity action and sustained effort during play of longer duration. Flexibility leads to higher range of motion, reduced incidence of injury, and better implementation of volleyball-related skills (Palao, Manzanares, & Valades, 2014; Ziv & Lidor, 2010).

Physical fitness evaluation is an important step in talent identification and athlete development programmes. Studies have shown that physical fitness characteristics play a major role in ensuring or deterring volleyball performance, and can also be used to forecast competitive success for young competitors (Gabbett, Georgieff & Domrow, 2007). Accordingly, coaches and sports scientists need credible and reliable testing techniques to detect capable individuals, follow training adjustment, and assess athlete performance. There have been various physical fitness tests that have been implemented for general athletic populations; however, there is still no such comprehensive, standardized test battery developed for the age group of adolescent volleyball players. Current evaluation standards frequently emphasize the single fitness factors and may not adequately capture the multidimensional physical nature of volleyball. Also, many existing tests have been created for adult athletes, preventing their generalization to teenagers.

Therefore we want to design and validate a reliable scientifically sound test battery that is capable of accurately assessing the physical fitness characteristics needed for volleyball performance in adolescence.

To develop a test battery, it is a reasonable and systematic procedure to identify relevant performance variables, evaluate with expert personnel, conduct pilot testing, and determine valid, reliable, and objective psychometric properties of the test battery. A scientifically validated test battery should be able to deliver accurate, comparable, and meaningful measurements that are also applicable at varying levels of competition. Professionals in measurement have been quick to stress that testing protocols are critical for obtaining reliable information and enabling objective evaluation of athletes (Kirkendall, Gruber, & Johnson, 1987; Morrow, Mood, Disch, & Kang, 2016).

Factor analytic methods are an efficient way to determine the underlying dimensions of physical fitness and to choose the best test items. Factor-based analyses reduce a number of variables into a smaller group of meaningful factors which contribute to efficient utilization of test batteries. Field (2005) further points out that Principal Component Analysis and Varimax Rotation are well-known methods for determining dominant factors and discovering those variables that best correspond to the construct being studied. Normative standards were also a key issue on the path of test battery development. Norms allow coaches and practitioners to categorize athletes based on performance, as well as permit a comparison of players of comparable age and standards of competition. Percentile norms and T-score scales are often used to interpret performance results and to produce standardized assessment measures (Thomas, Nelson, & Silverman, 2023).

The current study was conducted to create and validate an extensive test battery measuring physical fitness in adolescent volleyball players. To do this, this study aims to determine the most important physical fitness variables associated with volleyball performance, establish the validity, reliability, and objectivity of selected test items, analyze the factor structure in relation to factor-structure relationships among players, and develop normative standards for the evaluation of adolescents engaged in volleyball. This study is expected to have substantial contributions to scientific validation of volleyball performance, establishing similar standards for identification of talent, selection of individuals in the role of player, and long-term development of athletes.

REVIEW OF LITERATURE

As Sheppard, Gabbett, and Stanganelli (2009) state, elite volleyball performance is primarily determined by the player's ability to engage in explosive movement repeatedly while competing. According to the authors, physical fitness characteristics play a central role in distinguishing successful players from unsuccessful players. Likewise, Palao, Manzanares, and Valades (2014) carried out a study of volleyball players in various playing positions and performance levels. It was further found that the physical fitness of high individual playability significantly impacts volleyball-specific performance and competitiveness. The study emphasized that evaluating more than one type of fitness would lead to a better outcome than using one performance measurement.

Volleyball Speed is key in the sport of volleyball as players often play short distances and play with great speed under pressure on the court as an offensive and defensive player. Movement speed is a key determinant for a competitive performance where, according to Bompa and Buzzichelli (2019), it determines an athlete's ability to respond quickly and place himself appropriately on the court. In volleyball, speed makes the transition between attack and defense easier which, in turn, increases overall court coverage. Studies by Gabbett et al. (2007) established that speed-related features were effective predictors of selection of talented junior volleyball players. Speed assessment was therefore integrated according to the authors, as part of talent identification schemes and a key performance appraisals plan.

Agility is the capacity to turn quickly to gain control of the balance. Volleyball demands multiple modes of movement, so agility is key to success. Agility comprises physical, technical, and cognitive factors, and it has been

recognised as essential performance factor in sports that depend on the quick decision-making and movement manipulation that happens in fast movement environments (Young, James, & Montgomery, 2002). Miller and colleagues (2006) discovered that agility training significantly increased the efficiency of bodily movement in athletes and his sport-specific performance. Their results help provide support for considering agility measurement in comprehensive fitness assessment battery for volleyball players.

Power with power is commonly acknowledged as one of the most crucial physical attributes in volleyball. Spiking, blocking, jump serving, and different kinds of power action depend very significantly on greater lower-body explosive strength. As Ziv and Lidor (2010) found in their extensive review of the literature, vertical jump performance was highly predictive of success for volleyball in both male and female athletes. Sheppard et al. (2008) has also shown that explosive power variables discriminate elite and amateur volleyball players. Thus, jump performance assessments play a significant role in volleyball talent identification and performance evaluation. Typically, volleyball play may consist of long-duration bouts of activity followed by repeated high-intensity periods. Hence, muscular endurance is necessary for maintaining long-lasting performance in competition. Baechle and Earle (2008) indicated that muscular endurance has shown for resistance against fatigue and to the repeated performance of sport-specific movements. Studies have demonstrated that athletes who practice more muscular endurance had better success in consistency of technical performance for a duration of longer competition. This is very particularly concerning in young players who are experiencing such accelerated physical growth and change.

As a competitive sport, flexibility is an important factor when it comes to volleyball to help improve range of motion, movement efficiency, and reduce injury rates. Many volleyball skills involve activities requiring athletes to do movements that involve extreme joint position. Alter (2004) observed that enough flexibility is linked with improved athletic performance and fewer musculoskeletal injuries. Research on volleyball players has shown that flexibility may be associated with increased skill execution efficiency, especially in the delivery of a volleyball game (serve, spike, and pass) and in defense. As a result, assessment of flexibility is still an integral component of a holistic examination of physical fitness. Standardized test batteries have emerged as being an effective approach for performance evaluation, talent identification, and other sports science applications. The research of Kirkendall, Gruber and Johnson (1987) emphasized that a reliable test battery should achieve appropriate performance characteristics but have high levels of validity, reliability, and objectivity in assessing its effectiveness. Morrow et al. (2016) claimed that test batteries must comprise multiple variables that together embody the construct that is being measured. Full assessment system will give more accurate information of athlete performance than will isolated test of performance.

Validity, reliability and objectivity is the degree of agreement between evaluators. These qualities of the psychometric are important elements for any scientific instrument (Thomas, Nelson, and Silverman, 2023). Many researches emphasise significance to ensure the validity; reliability before implementing performance tests for the evaluating athlete programme. Predictable testing algorithms for talent identification and training prescription data enable the ability for precise identification of potential employees are validated with established test procedures that allow to make a sound selection of talent and training prescription.

MATERIALS AND METHODS

Research Design

The current research utilized a descriptive survey research design for the construction and testing of a total physical fitness test battery for youth volleyball players. The study consists of four stages: (i) identification in literature search and expert consensus of probable test items; (ii) pilot testing and preliminary screening of test items; (iii) assessment of validity, reliability and objectivity of selected tests; and (iv) establishment of norms and standardization of final test battery.

Participants

Around 550 adolescent volleyball players from different districts of Tamil Nadu were included in the study. Players will be recruited from schools, sports hostels, academies, Sports Development Authority of Tamil Nadu (SDAT) centres, Sports Authority of India (SAI) training centres, as well as district/state level volleyball teams. Participants age ranged from 13-18 years and the participants had experience of structured volleyball training and competition.

Inclusion Criteria

Participant selection was based on the following criteria:

1. Young male and female volleyball players aged 13-18.
2. Players who have attended a volleyball training at least one year in a systematic way.
3. Players who have also competed in inter-school, district, state, academy or recognized volleyball matches.
4. Players who are medically fit only selected.
5. Players who consent to be involved in the study.

Exclusion Criteria

Exclusively, the following population were excepted from the study:

1. Players less than 13 years or older than 18.
2. Players with less than one year of participation in volleyball training.
3. Athletes with recent musculoskeletal injury or surgery history.
4. Neurological, cardiovascular, respiratory and orthopedic conditions that affect performance.
5. Absences from the testing sessions for players.
6. Incomplete test participants.
7. Failure to complete all testing procedures.
8. Players who do not grant informed consent or whose parents/guardians are not providing consent.

Selection of Variables

The following variables on the physical fitness analysis was considered for the test battery after extensive literature research, specialist opinions and the detailed examination of the physical demands of volleyball. Speed. Agility. Explosive Power. Muscular Endurance. Flexibility. The field tests for each of the physical fitness components are analyzed from prior research and current sports performance batteries.

Expert Opinion Survey

A detailed questionnaire covering potential test items were developed and distributed to experts, such as:

1. Directors of Physical Education.
2. Physical Education/Sports-Sciences Professors.
3. Volleyball Coaches.
4. International and National Volleyball Players.
5. Sports Authority of India (SAI) Coaches.
6. Sports Development Authority of Tamil Nadu (SDAT) Coaches.

Experts were asked for insight into the significance of each test item in examining volleyball-specific physical fitness. They were also be invited to suggest a further series of test-items relevant to their level of fitness. To reduce the number of repeat trials and to rank more closely to the general population, the test items with higher scores and consensus are shortlisted for further analysis.

Pilot Study

A pilot study was run on a representative sample of adolescent volleyball players to assess the feasibility and fit of selected tests. The testing procedures were adapted according to the findings.

Administration of Tests

Finally, the shortlisted test items were administered under standardized conditions for the specified participants. Adequate warm-up and familiarization sessions were conducted prior to the assessment. Qualified assessors were perform the tests according to an established protocol.

Reliability, Validity, and Objectivity

Reliability: To establish test-retest reliability, they were repeated the tests twice with enough interval. Reliability coefficients will be found by Pearson Product Moment Correlation.

Validity: Content validity was confirmed by expert's opinion. Factor analytic procedures will be used to evaluate construct validity.

Objectivity: Objectivity was established by comparing scores recorded independently by two qualified evaluators and calculating inter-rater correlation coefficients.

Statistical Analysis

Following statistical analysis Descriptive statistics, Pearson Product Moment Correlation, Reliability Analysis, Factor Analysis, Principal Component Analysis (PCA), Varimax Rotation, Percentile Norms, T-Score Norms were done for the data collected.

RESULTS

Table 1 shows the expert opinion as to the importance of physical fitness components chosen for volleyball performance in adolescent players. Speed received more expert support (94%) followed by agility (92%), explosive power (90%), muscular endurance (84%), and flexibility (80%). The following variables were retained for further analysis and inclusion into the development of the test battery as they all obtained over 75 percent agreement. Those findings reflect a strong consensus from those experts that these five components are critical determinants of volleyball performance. Table 2 presents the test-retest reliability coefficients obtained for the physical fitness tests chosen. The objectivity coefficients from inter-rater reliability analysis are presented in Table 3. The coefficients ranged from 0.89 to 0.96, indicating overall high agreement between the evaluators. The Vertical Jump Test achieved the most objectivity agreement in terms of coefficient ($r = 0.96$) while the Bent-Knee Sit-Up Test had the least agreement ($r = 0.89$). As the result of this study confirms, the tests selected can be both administered and scored consistently by different evaluators, thereby ensuring objectivity of measurement. The inter-correlations of the chosen physical fitness variables are shown in Table 4. Significant positive correlations were observed among all variables, indicating that they are related yet measure distinct aspects of physical fitness. Speed and agility had the highest correlation ($r = 0.681$), and thus are believed to have similar performance characteristics. Speed and flexibility showed the lowest correlation ($r = 0.321$). The moderate correlations, however, supported the use of factor analysis to determine the fundamental aspects of physical fitness performance.

The Kaiser-Meyer-Olkin (KMO) Measure of Sampling adequacy and Bartlett's Test of Sphericity are provided in Table 5. The KMO of 0.864 was greater than the recommended minimum value of 0.60, demonstrating good sampling adequacy. In addition, Bartlett's Test of Sphericity yielded a noteworthy chi-square value ($\chi^2 = 1875.42$, $p < 0.001$) verifying the correct correlation matrix was applicable for factor analysis. The data demonstrated the appropriateness for Principal Component Analysis based on these findings. Table 6 shows the total variance explained using the principal components extracted. The first component explained 43.00 percent of the variation, and the remaining four components accounted for 18.40 percent, 14.20 percent, 11.20 percent, and 8.20 percent, respectively.

Table 7 shows the rotated module matrix using Varimax Rotation. Table 8 presents the final physical fitness test battery developed for adolescent volleyball players. Table 9 outlines the percentile norms and these norms sustenance the identification and classification of unique talent performance.

DISCUSSION

This finding is in line with current volleyball literature, which describes volleyball as a high-intensity intermittent sport involving fast acceleration, explosive jumping, movement in multiple directions, and repeated muscular effort (Sheppard, Gabbett, & Stanganelli, 2009). Marques, van den Tillaar, Vescovi and Gonzalez-Badillo (2008) also add that speed and power traits of a volleyball player are key components of successful performance. Coefficients on measurements from reliability analysis were set between 0.87 and 0.94, indicating strong consistency of measurement. The two sets of values are above the minimum requirement for acceptable reliability in performance measures in sports and indicate that the chosen tests are able to provide stable and reproducible results. According to Hopkins (2000), reliability coefficients greater than 0.80 reflect acceptable measurement stability for sports science use. Atkinson and Nevill (1998) stressed the importance of ensuring reliable tests in order to minimize measurement error and increase confidence in performance measurement. The findings presented in this study also coincide with Morrow, Mood, Disch, and Kang (2016) who recommend the use of very reliable tests in athlete assessment and talent identification. Objectivity coefficients of 0.89 to 0.96 showed a high level of agreement between evaluators. This indicates that the chosen tests can be administered consistently by various testers with minimal scorer bias. In line with this notion, this document indicates that objectivity is one of the fundamental psychometric attributes that promotes fairness and validity in performance assessment (Thomas, Nelson, & Silverman, 2023).

The high level of objectivity reached in the current study hence reinforces the implementation of the introduced test battery into education settings, sports academies and talent development programs. The inter-correlation study showed substantial relationships between the chosen physical fitness factors. Faster training has been linked with more agility, so the more acceleration in a sprint, the faster it is, giving athletes with superior agility the best indication to adopt and improve their change of direction speed and movement efficiency. These results support Young, James, and Montgomery (2002) that reported speed and agility have similar neuromuscular and biomechanical underpinnings. On the other hand, the correlations were statistically modest, indicating that individual variables each yield unique information related to volleyball performance. This is a supportive aspect of having several fitness components in a full assessment battery, and the findings reflect the multidimensional nature of athletic performance. The Kaiser-Meyer-Olkin value of 0.864, and the significant Bartlett's Test of Sphericity proved the appropriateness of the dataset for factor analysis. Field (2005) states that KMO > 0.80 means that sampling adequacy is excellent as well as that it is feasible for the extraction of valid factor structures. Hence, the successful use of Principal Component Analysis applied in this study validates the appropriateness of the selected variables and sample size for test battery development.

Further, factor analysis revealed five separate factors that were associated with speed, agility, explosive power, muscular endurance, and flexibility. The selected variables explained around 95% of the variance, confirming that the selected variables represented the physical fitness construct which is necessary for volleyball performance. Hair, Black, Babin, Anderson and Tatham (2019) argued that factor solutions, which accounted for large percentages of variance, are strong evidence for construct validity. This data thus confirm the theoretical perspective that volleyball performance is affected by many interconnected physical abilities. Of these determined factors, the 50-meter sprint test showed the most satisfactory performance indicator. Volleyball players are expected to react quickly and be able to effectively move across the court in offensive and defensive scenarios. Movement speed is the key factor in court coverage and tactical effectiveness in team sports (Bompa and Buzzichelli, 2019). Similarly, Gabbett and Georgieff (2007) identified speed-related variables to make an impact on which junior volleyball talent they recruited. According to Baechle and Earle (2008) muscular endurance will play a key role in endurance performance and resting between repeated interventions. Incorporating muscular endurance during the final battery demonstrates its

significance to delivering stable effects during all-competition bouts. Flexibility, reflected in the sit-and-reach test, also became a significant aspect of the last test battery.

Volleyball players perform movements that typically involve great movements, and especially defensive actions, spiking and blocking. Flexibility increased the efficiency of movement (Alter, 2004), technical execution, and reduces the injury risk. In recent studies, Behm, Blazevich, Kay and McHugh (2016) found that even within sports such as volleyball and basketball fitness flexibility enhances both athletic performance and prevents injuries. Consequently, the present study provides evidence that flexibility assessment should have an intrinsic role in the evaluation of volleyball fitness assessment. The current experimental findings produced important results including metric norms and the T-score criteria for adolescent volleyball players. Normative standards offer valuable guidelines for assessing athletes and for classifier of performance. Norm-referenced evaluation is foundational to talent identification and long-term monitoring of athletes as highlighted by Baumgartner, Jackson, Mahar, and Rowe (2015). Consequently, the normative data constructed in the present study provides meaningful insights to practitioners, coaches, physical educators, and sports scientists aiming to observe talent identification and developmental improvement.

Moreover, the results of the presented study corroborate the principles of Long-Term Athlete Development (LTAD) model, as it is developed by Balyi and Hamilton (2004) to systematic assessment of physical fitness characteristics during adolescence. Given that adolescence is pivotal for the development of both physical as well as psychological capability and development of specialized performance, the use of a standardized assessment battery can help coaches to better understand an athlete's current strengths and weaknesses and develop individually based training programs. In addition, the multi-dimensional structure found in this study is in accordance with Slimani, Miarka, Bragazzi, and Chamari (2018) that posited that a combination of physical, physiological, anthropometric, and technical characteristics were essential for successful volleyball performance. Their review called for holistic assessment systems that were able to account for the intricate nature of volleyball performance. Thus, this study will aim to provide a scientifically validated standardized physical fitness test battery specifically engineered for adolescent volleyball players.

CONCLUSION

1. This study was able to successfully develop and validate a full physical fitness test battery for adolescent volleyball players. Five physical fitness elements speed, agility, explosive power, muscular endurance, and flexibility were found to constitute major determinants of volleyball performance. The selected tests yielded satisfactory reliability, validity and objectivity.
2. The final battery included the 50 m Sprint Test, Shuttle Run Test, Vertical Jump Test, Bent-Knee Sit-Up Test, and Sit-and-Reach Test. Factor analysis exposed volleyball-specific fitness as multidimensional, while percentile and T-score norms served as impartial yardsticks for presentation measurement and classification.
3. It was determined that the test battery designed is a valid, reliable, objective, and practical instrument for talent detection, player assessment, and long-term athlete development in adolescent volleyball players.

ACKNOWLEDGEMENT

The authors would like to extend their deep gratitude to volleyball players, Directors of Physical Education, Volleyball Coaches and experts for their ideas and cooperation to conduct this study successfully.

Conflict of Interest

The authors announce that there is no conflict of interest regarding the publication of this study.

ABSTRACT

Antibiotics are among the most important commercially exploited secondary metabolites produced by microorganisms, particularly soil-dwelling bacteria, which thrive in highly competitive environments. Soil microbes, especially members of the genera *Bacillus*, *Streptomyces*, and certain fungi, are well recognized for their ability to produce a wide range of bioactive compounds. In the present study, a soil bacterium exhibiting significant antibiotic activity was isolated and characterized based on its morphological features. The antibacterial potential of the isolate was evaluated against selected opportunistic microbial pathogens using agar-based inhibitory assays. The organism was cultivated in suitably designed media and incubated at 37 °C for 48 h, followed by solvent extraction of the bioactive compound. Optimization of antibiotic production was carried out by varying physicochemical parameters such as temperature, pH, carbon source concentration, and sodium nitrate levels, with the aim of enhancing yield for possible industrial application. The extracted compound demonstrated notable inhibitory activity against Gram-positive endospore-forming bacilli and Gram-positive cocci.

In parallel, an eco-friendly green synthesis approach was employed to produce copper nanoparticles (Cu NPs) using *Tridaxprocumbens* leaf extract as a reducing and stabilizing agent. The formation of Cu NPs was confirmed by UV–visible spectroscopy, showing surface plasmon resonance at 320 nm. Further

characterization using FT-IR revealed the involvement of phenolic and other reactive functional groups in nanoparticle synthesis. SEM and XRD analyses confirmed the crystalline nature and morphology of the nanoparticles, with an average particle size of approximately 71 nm. The biosynthesized Cu NPs exhibited strong antibacterial activity against multiple pathogenic strains and demonstrated effective antioxidant potential. Additionally, the Cu NPs showed significant dye degradation capability, achieving nearly 89% degradation of Bismarck Brown dye within 72 h, with minimal phytotoxic effects.

Overall, this integrated study highlights the potential of antibiotic-producing soil bacteria and *Tridaxprocumbens*-mediated copper nanoparticles as promising natural and sustainable antibacterial agents with additional environmental applications.

Keywords : Antibiotic-producing soil bacteria; *Tridaxprocumbens*; Copper nanoparticles; Green synthesis; Antibacterial activity; Dye degradation.

INTRODUCTION

Antibiotics are bioactive compounds composed of small organic molecules that, even at low concentrations, influence the growth and metabolic pathways of other organisms [1]. Natural products derived from microorganisms have long served as the primary source of clinically important antibiotics and continue to represent one of the most promising avenues for the discovery of novel antimicrobial agents [2]. To date, the majority of commercially available antibiotics originate from soil-dwelling microorganisms, particularly fungi and actinomycetes [3]. Soil constitutes a complex and dynamic ecosystem formed through the weathering of rocks and enriched by organic matter over geological time [4]. Although the Earth formed approximately four to six billion years ago, microbial life has existed for more than three and a half billion years, leading to the observation that for much of Earth's history, it has been predominantly a "world of bacteria" [5]. Bacteria, typically measuring around 2.0 μm, represent the most abundant group of prokaryotes in soil environments, with populations reaching approximately 3×10^9 cells per gram of agricultural soil [6]. Soil microorganisms can be broadly classified into permanent soil inhabitants and transient organisms, and their diversity is influenced by several physicochemical factors, including soil type, moisture content, oxygen availability, pH, temperature, salinity, and nutrient composition [7]. Among soil bacteria, members of the genus *Bacillus* are particularly significant due to their ability to form resistant endospores and produce a wide range of antibiotics and bacteriocins that inhibit competing microorganisms [8]. Antibiotic-producing bacteria are relatively easy to isolate, culture, maintain, and genetically improve, making them attractive candidates for industrial antibiotic production [9]. Consequently, systematic screening of soil microorganisms remains a critical strategy in the search for new antibiotics to combat the growing challenge of antimicrobial resistance [10].

In parallel with microbial approaches, nanotechnology has emerged as a powerful tool in modern science for the synthesis of materials at the nanometer scale with controlled size, shape, and functionality [11]. Among various nanomaterials, metal nanoparticles have gained considerable attention for their biomedical and antimicrobial applications [12]. Copper nanoparticles (CuNPs) are particularly attractive due to copper's low cost, wide availability, and strong antimicrobial and catalytic properties [13]. Conventional methods for CuNP synthesis, such as thermal reduction, hydrothermal processes, and microwave-assisted techniques, often involve high energy consumption and the use of toxic chemicals, limiting their environmental and economic sustainability [14]. Green synthesis of nanoparticles using plant extracts has emerged as an eco-friendly alternative that eliminates hazardous reagents and utilizes naturally occurring phytochemicals as reducing and stabilizing agents [15]. *Tridaxprocumbens*, commonly known as coat buttons, is a medicinal plant rich in flavonoids, phenolics, and other bioactive compounds that facilitate the reduction of metal ions and stabilization of nanoparticles [16, 17]. Plant-mediated synthesis of CuNPs is influenced by parameters such as reaction time, temperature, pH, and extract concentration, which govern nanoparticle size, morphology, and stability [18]. Biosynthesized CuNPs have demonstrated promising antibacterial,

antioxidant, and environmental remediation properties [19, 20]. In this context, the present study integrates microbiological and green nanotechnological approaches by isolating antibiotic-producing soil microorganisms and synthesizing copper nanoparticles using *Tridaxprocumbens* leaf extract [21]. The antibacterial and antioxidant activities of both biological systems were evaluated, highlighting their potential as sustainable alternatives for antimicrobial and environmental applications [22].

MATERIALS AND METHODS

Collection, Authentication and Preparation of Extract

Fresh leaves of *Tridaxprocumbens* were collected from local fields and authenticated [23]. The leaves were thoroughly washed under running tap water followed by distilled water to remove debris and contaminants. Cleaned leaves were shade-dried to remove residual moisture and subsequently ground into a fine powder using a mechanical grinder. Five grams of the powdered leaf material were added to 100 mL of distilled water and boiled for 30 min. The extract was cooled, filtered through Whatman No. 1 filter paper, and stored at 4 °C for further use.

Green Synthesis of Copper Nanoparticles (CuNPs)

A 0.2 M copper nitrate solution was prepared by dissolving 3.7512 g of copper nitrate in 100 mL of distilled water [24]. For nanoparticle synthesis, 75 mL of copper nitrate solution was mixed with 25 mL of freshly prepared *T. procumbens* leaf extract. The reaction mixture was heated at 55 °C for 4 h with continuous stirring. A visible color change to sea green indicated the formation of CuNPs [25]. After cooling, the mixture was centrifuged to separate nanoparticles, which were subsequently dried using a water bath and stored at 4 °C for future analysis.

Screening of Phytocompounds

Preliminary qualitative phytochemical analysis of the *T. procumbens* leaf extract was performed using standard protocols to detect carbohydrates, proteins, phenolics, flavonoids, saponins, alkaloids, and tannins. Tests included Benedict's and Fehling's tests for carbohydrates; Ninhydrin and Biuret tests for proteins; gelatin and ferric chloride tests for phenolics and tannins; NaOH test for flavonoids; foam test for saponins; and Mayer's and Wagner's tests for alkaloids [26].

Characterization of Copper Nanoparticles

UV–visible spectroscopic analysis was carried out using a Labman UV spectrophotometer by scanning between 200 and 800 nm with distilled water as a blank [27]. Structural characterization was performed using X-ray diffraction (XRD, Smart Lab SE) to determine crystalline nature and particle size [28]. Surface morphology and size distribution were analyzed using scanning electron microscopy (SEM) [29].

Collection of soil samples

Soil samples were collected from different locations at a depth of 10–12.5 cm using a sterile spatula [30]. Samples were labeled (A, B, C, etc.) based on sampling location and transported to the laboratory in sterile containers for analysis.

Isolation of Soil Microorganisms

Serial dilution was performed by transferring 0.5 g of soil into 9 mL sterile distilled water, followed by successive dilutions [31]. Aliquots from appropriate dilutions were plated onto nutrient agar medium. Plates were incubated at 37 °C for 24 h, and distinct colonies were selected for further characterization.

Morphological and Biochemical Characterization

Gram staining was performed to determine Gram reaction and cellular morphology [32]. Biochemical tests including catalase, indole, methyl red, Voges–Proskauer, and citrate utilization tests were conducted following standard microbiological protocols [33].

Assay for antibacterial activity

The antibacterial activity of plant extract, CuNPs, and soil isolates was evaluated using the agar well diffusion method [34]. Pathogenic strains (*Escherichia coli* MTCC 443 and other test organisms) were standardized to 0.5 McFarland and spread on nutrient agar plates. Wells were loaded with samples, with ampicillin (100 µg/mL) as positive control and 5% DMSO as negative control. Plates were incubated at 37 °C for 24 h, and zones of inhibition were measured in millimeters.

Assay for antioxidant activity (DPPH method)

Antioxidant activity was determined using the DPPH radical scavenging assay [35,36]. A 1 mM DPPH solution was prepared in methanol. Various concentrations of CuNPs were mixed with DPPH solution and incubated in the dark for 15 min at room temperature. Absorbance was measured at 515 nm, and IC_{50} values were calculated.

RESULTS

Extraction and Phytochemical Analysis

The aqueous extract of *Tridaxprocumbens* was successfully prepared using 5 g of dried leaf powder boiled in 100 mL distilled water. Continuous stirring and heating at 60 °C for approximately 1 h resulted in efficient extraction of bioactive compounds. The filtered extract was stable and suitable for subsequent nanoparticle synthesis. Preliminary qualitative phytochemical screening revealed the presence of alkaloids, carbohydrates, phenolic compounds, flavonoids, and proteins (Table 1). Positive reactions observed in Wagner's, Benedict's, ferric chloride, lead acetate, and ninhydrin tests confirmed the richness of phytochemicals. These compounds are known to act as reducing and stabilizing agents during nanoparticle synthesis and contribute to antioxidant and antimicrobial activities

Isolation and Characterization of Soil Microorganisms

Soil samples collected from forest and agricultural field regions showed diverse microbial populations. Serial dilution and plating resulted in distinct colony formation, enabling isolation of bacterial strains (Fig. 1 and Fig. 2). Gram staining revealed that isolates from both forest and field soils were Gram-positive, rod-shaped bacteria (Fig. 3), suggesting their probable affiliation to the genus *Bacillus*, which is well known for antibiotic production. Biochemical characterization showed positive results for catalase and MR-VP tests and negative results for indole production in both isolates (Table 2). These biochemical traits further support the identification of antibiotic-producing *Bacillus*-like organisms. Such organisms possess competitive advantages in soil ecosystems due to their ability to produce antimicrobial metabolites that suppress rival microorganisms.

Antimicrobial Activity of Soil Isolates

Among the isolated strains, five showed prominent zones of inhibition against test pathogens and were selected for further screening. The antibacterial activity confirmed the presence of antibiotic-producing microorganisms capable of inhibiting pathogenic bacteria, emphasizing the importance of soil as a reservoir of bioactive microbes.

Green Synthesis and UV–Visible Analysis of CuNPs

The formation of copper nanoparticles was visually confirmed by a distinct color change of the reaction mixture. UV–visible spectroscopic analysis showed a characteristic surface plasmon resonance (SPR) peak at 403 nm, confirming the successful reduction of Cu^{2+} ions to CuNPs. The absorption peak aligns with reported values for biosynthesized copper nanoparticles and indicates nanoparticle stability.

XRD and SEM Analysis

X-ray diffraction analysis confirmed the crystalline nature of the biosynthesized CuNPs, with distinct diffraction peaks corresponding to copper crystalline planes. The sharp peaks indicate good crystallinity and successful nanoparticle formation. SEM images revealed that the CuNPs were predominantly asymmetric and needle-shaped, with particle sizes ranging from approximately 95 to 100 nm. Minor agglomeration was observed; however, the

phytochemical capping agents present in the plant extract appeared to limit excessive aggregation, contributing to nanoparticle stability

Antioxidant Activity

The antioxidant potential of the synthesized CuNPs was evaluated using the DPPH radical scavenging assay. The CuNPs exhibited concentration-dependent free radical scavenging activity. The IC_{50} value of the CuNP extract (64.47 mg/mL) was comparable to that of the standard antioxidant vitamin C (58.66 mg/mL), indicating significant antioxidant potential attributed to both copper and plant-derived phytochemicals.

Antibacterial Activity of CuNPs

The antibacterial activity of CuNPs was tested against *Staphylococcus aureus* and *Escherichia coli*. The zone of inhibition increased with increasing concentration of CuNPs, demonstrating dose-dependent antibacterial activity. The enhanced antimicrobial effect is likely due to nanoparticle interaction with bacterial cell membranes, generation of reactive oxygen species, and disruption of cellular metabolism.

DISCUSSION

The present study integrates classical soil microbiology with green nanotechnology to explore sustainable strategies for antimicrobial discovery and application [10,11]. The isolation of antibiotic-producing soil bacteria and the green synthesis of copper nanoparticles (CuNPs) using *Tridaxprocumbens* leaf extract collectively highlight the potential of natural systems in addressing the growing demand for effective antimicrobial agents [2,15]. The results obtained provide valuable insights into the biological activity of soil microorganisms and plant-mediated nanoparticles, as well as their possible synergistic relevance in biomedical and environmental applications [12,22]. Soil remains one of the richest reservoirs of microbial diversity and bioactive secondary metabolites [4,7]. In this study, bacterial isolates obtained from both forest and agricultural field soils exhibited Gram-positive, rod-shaped morphology and biochemical characteristics consistent with *Bacillus* species [8]. Members of this genus are well recognized for their ability to form endospores, which confer resistance to harsh environmental conditions, and for producing a wide range of antibiotics, including bacitracin and other bacteriocins [3,8]. The positive catalase and MR-VP reactions and negative indole tests observed in the isolates further support their probable taxonomic affiliation [32,33]. These findings are in agreement with earlier reports that identify *Bacillus* spp. as dominant antibiotic producers in soil ecosystems [9] due to their competitive survival mechanisms.

The antimicrobial activity exhibited by the selected soil isolates against pathogenic bacteria confirms their antibiotic-producing capability [9,10]. The formation of clear zones of inhibition indicates the secretion of diffusible antimicrobial compounds capable of suppressing pathogen growth [34]. Such activity emphasizes the continued relevance of soil-based screening programs for identifying novel antibiotic-producing microorganisms [2]. Despite the availability of numerous commercial antibiotics, the rapid emergence of antimicrobial resistance necessitates renewed exploration of natural microbial resources [10]. The isolates identified in this study may represent potential candidates for further purification, characterization, and optimization of antibiotic compounds for therapeutic use [9]. In parallel, the green synthesis of CuNPs using *Tridaxprocumbens* leaf extract represents an environmentally friendly alternative to conventional nanoparticle synthesis methods [14,15]. The successful formation of CuNPs was evidenced by a distinct color change and a characteristic surface plasmon resonance (SPR) peak observed in the UV–visible spectrum [25,27]. The absorption maximum at approximately 403 nm is consistent with previously reported values for biosynthesized copper nanoparticles [20,24] and confirms the reduction of Cu^{2+} ions by plant-derived phytochemicals. These phytochemicals, including flavonoids, phenolics, alkaloids, and proteins identified in the extract, act as both reducing and stabilizing agents, eliminating the need for toxic chemicals [16,18].

X-ray diffraction analysis confirmed the crystalline nature of the biosynthesized CuNPs, indicating successful nanoparticle formation with defined lattice structures [28]. The sharp diffraction peaks suggest good crystallinity,

which is an important parameter influencing nanoparticle stability and biological activity [12]. SEM analysis further revealed that the CuNPs exhibited predominantly asymmetric and needle-like morphologies, with particle sizes ranging from approximately 95 to 100 nm [29]. While some degree of agglomeration was observed, the presence of phytochemical capping agents likely minimized excessive aggregation, contributing to nanoparticle stability [18]. Particle size and morphology are critical determinants of nanoparticle–cell interactions and significantly influence antimicrobial efficacy. The antioxidant activity of the CuNPs, assessed through the DPPH radical scavenging assay, demonstrated a concentration-dependent response [35,36]. The IC_{50} value of the synthesized CuNPs was comparable to that of the standard antioxidant vitamin C, indicating substantial free radical scavenging potential [26]. This antioxidant property can be attributed to the combined effects of copper and the residual plant-derived phytochemicals adsorbed on the nanoparticle surface [19]. Antioxidant activity is particularly important in biomedical applications, as oxidative stress plays a key role in the progression of various diseases, including inflammation, cancer, and neurodegenerative disorders.

The antibacterial activity of the CuNPs against both *Staphylococcus aureus* and *Escherichia coli* further demonstrates their broad-spectrum antimicrobial potential [12,19]. The observed dose-dependent increase in zones of inhibition suggests that higher concentrations of CuNPs enhance bacterial growth suppression [34]. The antibacterial mechanism of CuNPs is believed to involve multiple pathways, including disruption of bacterial cell membranes, generation of reactive oxygen species, interference with protein synthesis, and damage to nucleic acids [12,20]. The small size and high surface area of nanoparticles facilitate close interaction with bacterial cells, leading to increased antimicrobial efficiency. When compared to traditional antibiotics, metal nanoparticles offer several advantages, including multi-target modes of action and reduced likelihood of resistance development [12]. The combined findings of this study suggest that CuNPs synthesized via green methods could serve as promising alternatives or adjuncts to conventional antibiotics [19]. Moreover, the antimicrobial properties of both soil-derived bacterial metabolites and CuNPs highlight the potential for integrated approaches in combating pathogenic microorganisms [22]. Overall, the results of this study demonstrate that soil microorganisms and plant-mediated nanoparticles are valuable natural resources for the development of sustainable antimicrobial agents [10,11]. The integration of microbial biotechnology with green nanotechnology not only reduces environmental impact but also enhances biological efficacy [15]. Future studies should focus on the purification and molecular characterization of the antibiotic compounds produced by the isolated bacteria, as well as detailed toxicity and mechanistic studies of CuNPs. Additionally, exploring synergistic interactions between microbial antibiotics and nanoparticles could open new avenues for the development of next-generation antimicrobial therapies [12,22].

CONCLUSION

In conclusion, the present study demonstrates that soil ecosystems and plant-mediated green nanotechnology serve as rich and sustainable sources of antimicrobial and antioxidant agents. The isolation of Gram-positive, rod-shaped antibiotic-producing bacteria from soil highlights the continued relevance of soil microorganisms in the discovery of bioactive compounds with therapeutic potential. Simultaneously, the successful green synthesis of copper nanoparticles using *Tridaxprocumbens* leaf extract confirms the role of plant phytochemicals as effective reducing and stabilizing agents. The biosynthesized CuNPs exhibited notable antioxidant and antibacterial activities, comparable to standard controls, and showed promising physicochemical characteristics. Together, these findings emphasize that integrating traditional microbiological approaches with eco-friendly nanotechnology offers a viable and environmentally responsible strategy for developing novel antimicrobial agents with potential biomedical and environmental applications.

ABSTRACT

Conventional forensic risk assessment instruments rely predominantly on psychosocial, developmental, and criminological variables to predict violent and antisocial behaviour, leaving biological and metabolic dimensions of vulnerability largely unaddressed. This paper introduces Forensic Nutrition Profiling (FNP), a novel interdisciplinary conceptual framework that systematically integrates nutritional biomarkers, diet quality indices, stress physiology markers, and standardised behavioural instruments into a composite forensic assessment model. The FNP framework is organised around four weighted domains: Nutritional Biomarkers (40%), Diet Quality (20%), Stress and Physiology (20%), and Behavioural Markers (20%), yielding a Composite FNP Risk Score (0–100) stratified into four actionable risk tiers. Key biomarkers proposed for inclusion encompass the omega-3 index, Vitamin D (25(OH)D), ferritin, B-vitamins (B6, B9, B12), zinc, magnesium, cortisol diurnal rhythm, C-reactive protein (CRP), and glycaemic markers, each analytically quantifiable using established forensic laboratory methods. The scientific basis for FNP draws on mechanistic evidence linking nutritional deficits to impaired neurotransmitter synthesis, dysregulated hypothalamic-pituitary-adrenal (HPA) axis activity, systemic neuroinflammation, and compromised executive functioning all established neurobiological antecedents of reactive aggression. Convergent evidence from randomised controlled trials demonstrates that targeted nutritional supplementation reduces aggressive behaviour in high-risk populations, most notably a 26.3% reduction in institutional violent incidents with combined vitamin, mineral, and essential fatty acid supplementation (Gesch et al., 2002), supporting the feasibility of FNP as both an assessment and intervention-planning tool. FNP is positioned not as a replacement for existing forensic risk instruments such as the HCR-20 or VRAG-R, but as a biologically grounded complement that adds a nutritional and metabolic dimension currently absent from all established tools. The framework offers particular translational relevance for custodial settings, preventive forensic psychiatry, and offender rehabilitation planning, and establishes a clear empirical validation agenda for clinical implementation.

Keywords: Forensic Nutrition Profiling; FNP; nutritional biomarkers; aggression; impulsivity; omega-3 fatty acids; cortisol; forensic risk assessment; nutritional psychiatry; framework proposal; antisocial behaviour; violence prevention.

INTRODUCTION

The assessment and prediction of violent and antisocial behaviour constitute foundational challenges in forensic science, psychiatry, and criminology. Over several decades, the field has developed increasingly sophisticated risk instrumentsfrom the Historical Clinical Risk Management scale (HCR-20; Webster et al., 1997) and the Violence Risk Appraisal Guide-Revised (VRAG-R; Quinsey et al., 2006) to dynamic tools such as the Short-Term Assessment of Risk and Treatability (START; Webster et al., 2009). These instruments have substantially advanced the precision of violence risk prediction. However, they share a common limitation: they conceptualise violence risk almost exclusively in psychosocial, criminological, and psychiatric terms, leaving biological and metabolic dimensions of vulnerability largely unaddressed (Raine, 2018). A growing interdisciplinary literature in nutritional psychiatry, behavioural endocrinology, and forensic neuroscience challenges this exclusion. Nutrients serve not merely as substrates for physical health but as essential regulators of brain chemistry, neural circuit integrity, and the physiological stress response — all of which directly modulate the propensity for impulsive and reactive aggression (Benton, 2010; Gajos & Beaver, 2016). Omega-3 fatty acids govern neuronal membrane fluidity and neuroinflammation; B-vitamins and zinc act as obligate cofactors in serotonin and dopamine synthesis; iron underpins myelination and dopaminergic neurotransmission; and cortisol dysregulation shapes the threshold of stress-reactive aggression. Critically, deficiencies in these nutrients are not rare: they are prevalent in community, custodial, and forensic populations and are demonstrably remediable through dietary modification and targeted supplementation (Gesch et al., 2002; Raine & Brodrick, 2024).

Most compellingly, randomised controlled trials have demonstrated that nutritional supplementation encompassing omega-3 fatty acids, vitamins, and minerals produces statistically significant and clinically meaningful reductions in aggressive and antisocial behaviour in both juvenile and adult populations (Gesch et al., 2002; Raine et al., 2015; Raine & Brodrick, 2024). These findings carry a level of causal inference rarely achieved by psychological intervention research and constitute a powerful mandate for incorporating nutritional variables into forensic risk frameworks. It is within this context that the present paper proposes Forensic Nutrition Profiling (FNP): a novel, interdisciplinary conceptual framework designed to systematically integrate nutritional biomarkers, diet quality assessment, metabolic physiology, and standardised behavioural measures into a coherent composite model of aggression vulnerability. FNP does not assert that nutritional deficiency is the sole cause of violent behaviour; rather, it conceptualises nutritional vulnerability as a quantifiable, modifiable biological risk factor analogous in its forensic role to substance misuse, sleep disorder, or traumatic brain injury that interacts with psychosocial risk determinants to lower the threshold for reactive aggression. This paper presents the theoretical foundations, structural architecture, biomarker rationale, analytical methods, risk stratification logic, and translational applications of the FNP framework. It is intended to serve as a foundational conceptual contribution that will guide future empirical validation studies, clinical protocol development, and eventual integration into forensic assessment practice.

Background and Rationale: The Nutritional Gap In Forensic Science

Limitations of Current Forensic Risk Frameworks

Contemporary forensic risk assessment instruments have been refined over decades of actuarial and clinical research. Structured professional judgement tools such as the HCR-20 V3 integrate static historical variables (prior violence, early maladjustment, personality disorder) with dynamic clinical indicators (active psychosis, impulsivity, treatment response) and risk management considerations. Actuarial tools such as the VRAG-R assign weighted scores based on criminological and diagnostic predictors, producing probabilistic risk classifications. Both approaches demonstrate good predictive validity for institutional violence and community recidivism, with area under the receiver operating characteristic (AUC-ROC) values typically in the range of 0.70–0.80 (Fazel et al., 2012). Yet these instruments share a systematic blind spot: they do not assess the neurobiological and physiological substrate of the individual at the time of evaluation. An individual's risk score on the HCR-20 remains identical whether their omega-3 index is in the lowest decile or the highest, whether they are profoundly iron-deficient with blunted dopaminergic transmission, or

whether their cortisol diurnal rhythm is severely flattened. This biological information — empirically related to aggression risk and analytically obtainable — is entirely absent from the forensic evaluation process, representing not merely a theoretical gap but a practical one. FNP is designed precisely to close this gap.

Nutritional Psychiatry and Behavioural Neuroscience: Convergent Evidence

The scientific case for incorporating nutritional variables into forensic assessment rests on three converging lines of evidence: (i) mechanistic studies establishing causal pathways from nutritional status to neurochemical and physiological processes that modulate aggression; (ii) observational epidemiological studies demonstrating associations between dietary patterns, nutritional deficiencies, and aggressive or antisocial behaviour; and (iii) randomised controlled trials demonstrating that correcting nutritional deficiencies reduces aggressive behaviour in high-risk populations. Mechanistically, serotonin whose synthesis depends on dietary tryptophan availability and B-vitamin cofactor supply is the principal neurochemical brake on impulsive aggression; serotonin depletion has been consistently associated with increased reactive violence across species, clinical populations, and experimental paradigms (Benton, 2010; Kennedy, 2016). Dopaminergic pathways, dependent on tyrosine availability and iron-dependent enzymatic activity, regulate executive control, reward discounting, and the inhibition of prepotent aggressive responses (Beard, 2008). Omega-3 fatty acids modulate the density and function of prefrontal serotonin and dopamine receptors, maintain neuronal membrane fluidity, and suppress microglial neuroinflammation processes that collectively underpin affective regulation and impulse control (Hibbeln et al., 2006).

Epidemiologically, studies across diverse populations consistently link poor dietary quality, ultra-processed food consumption, and specific micronutrient deficiencies to elevated aggression scores, higher rates of conduct disorder, and increased violent offending (Jacka et al., 2017; Gajos & Beaver, 2016). The most compelling evidence comes from randomised controlled trials. Gesch et al. (2002) demonstrated a 26.3% reduction in institutional violent incidents in young adult prisoners randomised to receive vitamins, minerals, and essential fatty acids compared to placebo. Raine et al. (2015) showed that omega-3 supplementation significantly reduced internalising and externalising behavioural problems in children aged 8–16 years. A subsequent meta-analysis by Raine and Brodrick (2024) reported a pooled effect size ($d \approx 0.60–0.70$) for omega-3 supplementation on aggression reduction an effect magnitude comparable to, or exceeding, established psychological interventions for violence.

Positioning FNP Within Forensic Science

FNP is not proposed as a replacement for existing forensic risk assessment instruments. It is designed as a complementary biological layer within a broader multi-domain assessment architecture. Just as forensic neuropsychological evaluation augments psychiatric risk assessment by characterising individual cognitive vulnerabilities, FNP augments psychosocial risk profiling by characterising the biological, nutritional, and physiological substrate of aggression susceptibility. This aligns with the biosocial approach to criminology advocated by Raine (2018), which argues that biological and social determinants of violence are interacting causal contributors that a comprehensive risk science must account for simultaneously. Critically, FNP identifies modifiable risk factors: nutritional biomarker deficiencies and dietary patterns are remediable, giving FNP a dual function as both a risk stratification tool and a framework for targeting evidence-based nutritional interventions within forensic and rehabilitative settings.

The Forensic Nutrition Profiling Framework: Structural Architecture

Conceptual Foundation and Design Principles

The FNP framework is built on three core design principles. First, biological grounding: every biomarker included in the FNP panel is selected on the basis of documented mechanistic links to neurotransmitter synthesis, neural circuit function, stress physiology, or neuroinflammation each independently associated with aggression or emotional dysregulation. Second, analytical tractability: all proposed biomarkers are quantifiable using validated forensic-grade analytical methods already present in established forensic toxicology and biochemistry laboratories. Third, clinical actionability: each FNP risk tier is associated with a defined response pathway rom monitoring through nutritional intervention to multidisciplinary forensic management ensuring that assessment findings translate directly into

rehabilitation and risk management actions. The FNP framework is organised around four weighted assessment domains. These domains interact within an integrated biological system: nutritional biomarker status determines the biochemical substrate for neurotransmitter synthesis and stress physiology; diet quality is the primary upstream determinant of biomarker status; physiological stress markers reflect the functional consequences of dietary and nutritional inadequacy; and behavioural markers provide the phenotypic expression of underlying biological vulnerabilities. Composite scoring across these domains produces an FNP Risk Score (0–100) stratified into four actionable risk tiers.

Domain I — Nutritional Biomarkers (Weight: 40%)

Nutritional biomarkers constitute the core of the FNP model, carrying the highest weighting (40%) in recognition of their direct mechanistic role in the neurochemical and physiological determinants of aggression. Six primary biomarker categories are proposed:

- **Omega-3 Index (EPA + DHA):** Measured in erythrocyte membranes by gas chromatography–mass spectrometry (GC-MS), the omega-3 index provides a 120-day integrated measure of essential fatty acid status. Low omega-3 index has been prospectively associated with impulsivity, affective dysregulation, and reactive aggression (Hibbeln et al., 2006; Raine & Brodrick, 2024).
- **Vitamin D (25(OH)D):** Serum 25-hydroxyvitamin D serves as a functional neurosteroid, modulating the transcription of genes encoding serotonin synthesis enzymes (TPH2) and neurotrophin (BDNF) production in limbic circuits. Deficiency (<50 nmol/L) has been associated with mood dysregulation, irritability, and heightened aggression risk (Anglin et al., 2013).
- **Ferritin (Iron Status):** Serum ferritin is the primary indicator of iron stores. Iron is an essential cofactor for tyrosine hydroxylase (the rate-limiting enzyme in dopamine synthesis) and for myelination of prefrontal-subcortical circuits. Iron deficiency is associated with dopaminergic transmission deficits, cognitive slowing, and heightened behavioural reactivity (Beard, 2008).
- **B-Vitamins (B6, B9, B12):** These vitamins function as obligate enzymatic cofactors in the methylation and conversion of amino acid precursors to active monoamine neurotransmitters. B12 and folate are also essential for homocysteine remethylation; elevated homocysteine is an independent marker of neurotoxicity. Deficiency of any single B-vitamin can attenuate serotonergic and dopaminergic tone even when precursor amino acid supply is adequate (Kennedy, 2016).
- **Zinc:** A structural component of over 300 metalloenzymes, zinc modulates NMDA receptor function, synaptic plasticity, and neuronal inhibitory tone. Zinc deficiency is associated with impaired glutamatergic neurotransmission, dysregulated amygdala reactivity, and heightened aggression in both animal models and human clinical populations (Choy, 2023).
- **Magnesium:** Magnesium regulates NMDA receptor activity, modulates the HPA axis stress response, and suppresses cortisol hypersecretion under psychosocial challenge. Hypomagnesaemia is associated with emotional volatility, heightened anxiety, and amplified stress-reactive aggression (Choy, 2023).

Domain II — Diet Quality (Weight: 20%)

Diet quality operates as the primary upstream determinant of nutritional biomarker status and constitutes a modifiable risk factor in its own right. The FNP framework proposes assessment of diet quality through three complementary approaches: (i) quantification of ultra-processed food intake using the NOVA classification system; (ii) estimation of total daily glycaemic load from 24-hour dietary recall data; and (iii) calculation of a composite diet quality score using the Alternate Healthy Eating Index (AHEI) or the Dietary Approaches to Stop Hypertension (DASH) score, both of which have demonstrated associations with mental health and cognitive outcomes (Jacka et al., 2017). Diets dominated by ultra-processed foods systematically deplete the nutritional substrates assessed in Domain I and promote systemic inflammation through gut dysbiosis, increased intestinal permeability, and pro-inflammatory eicosanoid production.

Domain III — Stress and Physiology (Weight: 20%)

This domain captures the functional physiological consequences of nutritional inadequacy on the individual's stress response system and inflammatory burden. Three markers are proposed:

- **Cortisol Diurnal Rhythm:** Salivary cortisol is collected at four standardised time points (awakening, +30 minutes [cortisol awakening response, CAR], 14:00, and 21:00) using validated Salivette® collection methodology. Dysregulation of the diurnal cortisol slopecharacterised by a flattened or inverted pattern, blunted CAR, or hypocortisolism reflects chronic HPA axis dysregulation and has been consistently associated with reactive aggression, antisocial personality, and conduct disorder (McEwen, 2007).
- **High-Sensitivity C-Reactive Protein (hsCRP):** hsCRP is the most widely validated marker of systemic low-grade inflammation in clinical and community research. Elevated hsCRP reflects the neuroinflammatory state produced by diets high in ultra-processed foods, omega-3 deficiency, and gut dysbiosis. Neuroinflammation suppresses prefrontal serotonin transporter expression, increases microglial activation, and impairs executive functioning (Miller et al., 2009).
- **Sleep Quality Index:** Poor sleep quality, assessed via the Pittsburgh Sleep Quality Index (PSQI) or objective actigraphy, amplifies both cortisol reactivity and the neurobiological consequences of nutritional deficiency. Sleep deprivation independently reduces prefrontal cortical inhibitory control and increases amygdala reactivity, potentiating aggression under frustrating conditions.

Domain IV — Behavioural Markers (Weight: 20%)

Behavioural instruments provide the phenotypic anchor for the FNP composite score, enabling alignment of biological risk profiles with observable behavioural tendencies. Three validated instruments are proposed: (i) the Buss–Perry Aggression Questionnaire (AQ-29), which assesses physical aggression, verbal aggression, anger, and hostility with robust psychometric properties in both community and forensic samples; (ii) the Barratt Impulsiveness Scale version 11 (BIS-11), which measures motor, attentional, and non-planning impulsivity and has been extensively validated in forensic populations; and (iii) the Difficulties in Emotion Regulation Scale (DERS-36), which characterises emotional dysregulation across six dimensions including non-acceptance, goal-directed behaviour, impulse control, awareness, strategies, and clarity. These instruments collectively profile the behavioural phenotype predicted to emerge from the neurochemical and physiological deficits captured in Domains I–III.

FNP Scoring Methodology and Composite Risk Calculation

Within-Domain Scoring

Within each of the four FNP domains, individual indicators are scored on a standardised three-point scale: 0 (adequate —within reference range), 0.5 (borderline approaching insufficiency or mildly elevated), and 1.0 (deficient or dysregulated below clinical threshold or clinically elevated). Reference ranges are drawn from established clinical laboratory normative data: for example, Vitamin D sufficiency is defined as ≥50 nmol/L (125 nmol/L optimal); omega-3 index adequacy as ≥8%; serum ferritin adequacy as ≥15 µg/L; and hsCRP low inflammation as <1 mg/L. Borderline classification is defined as within 20% of the threshold in the deficient direction. Within each domain, indicator scores are summed and normalised to a 0–1 domain sub-score.

Composite Score Calculation

The Composite FNP Risk Score is calculated as a weighted sum of domain sub-scores, reflecting the differential evidence base for each domain's contribution to aggression risk: FNP Score = (Nutritional Biomarker Domain Score × 0.40) + (Diet Quality Domain Score × 0.20) + (Stress & Physiology Domain Score × 0.20) + (Behavioural Marker

Domain Score × 0.20), scaled to a 0–100 range. This weighted architecture ensures that the strongest mechanistic domain (nutritional biomarkers) exerts the greatest influence on the composite score while preserving the informational contribution of contextual, physiological, and phenotypic domains.

Interpretation Principles

Several interpretation principles are essential to appropriate clinical use of the FNP score. First, the FNP score is a biological risk indicator, not a prediction of violence: high scores indicate elevated neurobiological vulnerability to reactive aggression under conditions of stress or provocation; they do not imply criminal intent or inevitability of violence. Second, FNP scores must always be interpreted within the full psychosocial context of the individual, including their trauma history, substance use, personality characteristics, social support, and environmental stressors. Third, the FNP score is dynamic: nutritional biomarker levels and dietary patterns change over time, and re-assessment following nutritional intervention is both feasible and clinically meaningful. Fourth, the FNP framework should be administered and interpreted by trained forensic practitioners with access to clinical dietetics expertise.

Analytical and Forensic Laboratory Methods

Biological Sample Collection

The FNP biomarker panel is designed for assessment using biological matrices routinely available in forensic and clinical biochemistry contexts. Fasting venous blood samples (10–15 ml) are recommended, collected in the morning to standardise cortisol and metabolic markers. Erythrocyte omega-3 index is quantified using gas chromatography–mass spectrometry (GC-MS) applied to erythrocyte membrane phospholipids, providing a 120-day integrated measure of EPA+DHA status. Serum 25(OH)D is quantified by liquid chromatography–tandem mass spectrometry (LC-MS/MS), the reference method for clinical Vitamin D assessment. Ferritin, hsCRP, and insulin are measured using validated immunoassay platforms (ELISA or chemiluminescence-based). B-vitamins (B6, B9, B12) and amino acid precursors (tryptophan, tyrosine) are quantified by high-performance liquid chromatography (HPLC) or LC-MS. Zinc is measured by inductively coupled plasma–mass spectrometry (ICP-MS) or validated atomic absorption spectrophotometry. Salivary cortisol is collected at four standardised time points using validated Salivette® collection kits, with strict adherence to sampling protocols to minimise pre-analytical variability, and quantified by ELISA or LC-MS/MS.

Hair and Nail Matrices

Hair and nail segments offer an important complementary forensic matrix, providing a historical record of chronic nutritional status rather than the acute snapshot captured by serum measurements. Hair elemental analysis by ICP-MS enables retrospective assessment of zinc, magnesium, and other trace element status over a 3–6 month window, corresponding to the rate of hair growth (~1 cm/month). These matrices are particularly valuable in forensic contexts where retrospective nutritional profiling is required for example, to characterise the nutritional environment in the period preceding a violent incident.

Emerging Analytical Approaches

Attenuated total reflectance Fourier-transform infrared (ATR-FTIR) spectroscopy represents an emerging rapid screening approach applicable to dried blood spots or tissue samples. This technique enables semi-quantitative profiling of multiple nutritional and metabolic markers simultaneously from minimal biological material, with potential applications in resource-limited forensic settings (Choy, 2023). Metabolomics platforms (untargeted LC-MS) offer the future prospect of comprehensive nutritional and metabolic phenotyping from a single biological sample, potentially enabling discovery of additional biomarker signatures not yet incorporated into the FNP panel.

Translational Applications and Implementation Pathways

Custodial and Correctional Settings

The most immediate translational application of FNP is within custodial and correctional environments, where controlled dietary conditions, captive populations, and high prevalence of both nutritional deficiency and violent

behaviour create an optimal setting for both framework implementation and intervention evaluation. Studies conducted in prisons consistently document high prevalence of omega-3 deficiency, iron insufficiency, low Vitamin D, and poor overall diet quality in incarcerated populations (Gesch et al., 2002). FNP provides a structured mechanism for identifying those prisoners whose nutritional profile places them at elevated biological risk for violent incidents and for directing targeted nutritional interventions toward the highest-risk individuals. The Gesch et al. (2002) randomised controlled trial provides a proof-of-concept demonstration: a combined vitamin, mineral, and fatty acid supplement reduced violent disciplinary incidents by 26.3% relative to placebo over 142 days in a young adult prison sample.

Forensic Psychiatric Assessment

Within forensic psychiatric services, FNP can augment existing structured professional judgement assessment of inpatients and community forensic patients. Forensic psychiatrists and psychologists conducting periodic risk reviews can incorporate FNP domain scores as a dynamic biological risk indicator, updated as nutritional status changes in response to dietary intervention, treatment, or environmental change. The FNP's risk tier classification (Table 3) generates actionable recommendations readily integrated into care planning: a patient whose FNP score moves from High to Moderate following three months of omega-3 supplementation and dietary improvement provides objective biological evidence of reduced physiological aggression vulnerability, informing decisions about leave, community placement, and security level.

Community Violence Prevention

FNP also has preventive applications in community forensic psychiatry, youth justice, and public health settings. Routine FNP screening of individuals on community forensic orders, those with a history of violent offending, or young people in early-intervention programmes could identify those with elevated nutritional vulnerability before violent incidents occur. This aligns with the evidence-based logic of nutritional criminology the proposition that dietary modification and nutritional supplementation can function as upstream violence prevention strategies with population-level impact and comparatively low cost (Choy, 2023; Raine, 2018).

Legal and Expert Witness Applications

In legal contexts, FNP findings may inform expert witness testimony regarding biological mitigating factors in cases involving reactive, impulsive aggression where the defendant's nutritional and physiological status at the time of the offence is relevant to culpability assessment. FNP's analytical grounding in validated laboratory methods and its evidence base in peer-reviewed science position it, in principle, to satisfy criteria for admissibility of scientific evidence under the Daubert or Frye standards. Legal application of FNP must, however, always be accompanied by explicit communication of its scope: FNP identifies biological vulnerability, not deterministic causation of violent acts.

Ethical Considerations and Boundaries of Application

The ethical deployment of FNP requires explicit attention to several dimensions. First and most fundamentally, FNP is a risk stratification tool, not a diagnostic test for criminal propensity. A high FNP composite score indicates elevated neurobiological vulnerability to reactive aggression; it does not predict, explain, or excuse any specific violent act, and must never be used as standalone evidence of dangerousness or criminal culpability. Second, the collection of biological samples for FNP assessment requires full voluntary informed consent, consistent with the Declaration of Helsinki and applicable national research ethics regulations. In custodial contexts, particular care must be taken to ensure that consent is genuinely free from institutional coercion, and that participation in FNP assessment is not linked to sentencing, parole, or security level decisions without explicit legal authorisation and robust procedural safeguards.

Third, nutritional biomarker data is sensitive health information and must be handled with the same confidentiality protections applied to other medical and psychiatric assessment data. Fourth, the deterministic misapplication of FNP for example, using a high FNP score to justify detention or deny parole in the absence of behavioural evidence

would constitute a serious violation of the framework's intended scope and the ethical principles of forensic science. Fifth, like all forensic instruments, FNP must be validated across diverse ethnic, socioeconomic, and cultural populations before generalisation, as nutritional reference ranges, dietary patterns, and microbiome composition vary substantially across populations.

Future Directions: Proposed Validation Agenda

The FNP framework, as a conceptual contribution, identifies a clear agenda for empirical validation and clinical translation. The following research priorities are proposed:

- **Cross-sectional validation studies:** Large-sample cross-sectional studies in forensic and community populations should characterise the distribution of FNP domain scores, examine their correlations with validated aggression and impulsivity instruments, and assess the discriminative validity of the composite FNP score against known aggression risk stratifications.
- **Longitudinal predictive validation:** Prospective cohort studies should follow individuals with varying FNP risk profiles over 12–24 months to assess the predictive validity of baseline FNP scores for incident violent behaviour, adjusting for established psychosocial risk factors.
- **Randomised controlled trials of FNP-guided intervention:** RCTs in custodial and forensic psychiatric settings should evaluate whether FNP-targeted nutritional interventions reduce aggression outcomes relative to standard care, using FNP composite score improvement as a secondary biological endpoint.
- **Instrument refinement and machine learning classification:** Machine learning approaches — including Random Forest classifiers, LASSO regression, and support vector machines — should be applied to FNP biomarker data to identify optimal biomarker subsets and scoring algorithms, improving classification accuracy for high-risk profiles.
- **Cross-cultural validation:** Independent validation studies in non-Western, non-industrial, and low- and middle-income country populations are essential to establish the cross-cultural generalisability of FNP reference ranges and risk tier thresholds.
- **Integration studies with existing risk instruments:** Studies should formally evaluate the incremental predictive validity of FNP composite scores when added to established instruments (HCR-20, VRAG-R, START), quantifying the degree to which FNP's biological dimension improves the AUC-ROC of standard forensic risk assessment batteries.

DISCUSSION

Forensic Nutrition Profiling represents a theoretically coherent, empirically grounded, and practically translatable innovation in forensic risk science. By drawing on over four decades of nutritional neuroscience, behavioural endocrinology, and randomised controlled trial evidence, FNP constructs a biological risk architecture for aggression that is simultaneously mechanistically plausible, analytically tractable, and clinically actionable. The framework does not challenge the validity or importance of existing forensic risk assessment instruments; it extends their reach by incorporating biological information that those instruments, by design, cannot capture. The most important conceptual contribution of FNP is the reconceptualisation of nutritional deficiency as a modifiable forensic risk factor. This has profound implications for how forensic practitioners, policymakers, and institutional administrators approach violence prevention. If a significant proportion of reactive aggression in custodial and forensic populations is partially attributable to remediable nutritional deficiencies as the randomised controlled trial evidence strongly suggests then the systematic failure to screen for and correct these deficiencies represents a missed opportunity for evidence-based violence reduction at scale.

The FNP model is deliberately conservative in its claims. It does not propose that nutritional factors are the primary cause of violent behaviour; the psychosocial, developmental, and psychiatric determinants that existing forensic instruments assess remain central. Rather, FNP proposes that nutritional vulnerability lowers the biological threshold at which these psychosocial risk factors precipitate violent action and that this threshold can be measured, quantified,

and raised through intervention. This is a modest but scientifically important claim, with practical consequences for both risk management and rehabilitation. Limitations of the framework as currently constituted must be acknowledged. The evidence base supporting individual FNP biomarkers varies in quality and consistency; the omega-3 index and cortisol diurnal rhythm have the strongest experimental support, while the independent contribution of individual micronutrients such as magnesium and zinc is less well characterised in forensic populations specifically. The composite scoring algorithm requires empirical calibration: the proposed domain weights are derived from the relative density of evidence rather than from empirically determined regression coefficients in a forensic validation sample. Future empirical work will refine and potentially revise this weighting structure as population-specific data become available.

CONCLUSION

This paper has introduced Forensic Nutrition Profiling (FNP) as a novel, interdisciplinary conceptual framework for integrating nutritional biomarkers, diet quality, metabolic physiology, and behavioural instruments into a composite model of aggression vulnerability for use in forensic assessment. FNP is grounded in a convergent body of mechanistic, epidemiological, and experimental evidence establishing nutrition as a modifiable biological determinant of the neurochemical and physiological processes that govern impulse control, emotional regulation, and reactive aggression. The framework proposes a four-domain composite scoring architecture yielding a Composite FNP Risk Score stratified into four actionable risk tiers, alongside a comprehensive biomarker panel analytically grounded in established forensic laboratory methods. FNP is positioned not as a replacement for existing forensic risk instruments but as a biologically grounded complement, adding a nutritional and metabolic dimension to risk assessment that current tools systematically omit. The translational significance of FNP lies in its dual function: as a risk stratification tool identifying individuals at elevated biological vulnerability to reactive aggression, and as a framework for targeting evidence-based nutritional interventions within forensic, custodial, and community settings. By establishing a clear agenda for empirical validation cross-sectional, longitudinal, and experimental this paper lays the groundwork for FNP to transition from conceptual framework to validated forensic assessment instrument.

Research Highlights

- Forensic Nutrition Profiling (FNP) is introduced as the first interdisciplinary framework integrating nutritional biomarkers into forensic risk assessment.
- A four-domain composite model (Nutritional Biomarkers 40%; Diet Quality 20%; Stress & Physiology 20%; Behavioural Markers 20%) yields a structured FNP Risk Score (0–100).
- Key biomarkers include the omega-3 index, Vitamin D, ferritin, B-vitamins, zinc, magnesium, cortisol diurnal rhythm, and C-reactive protein — all quantifiable by established forensic laboratory methods.
- Randomised controlled trial evidence demonstrates that targeted nutritional supplementation reduces aggressive behaviour in high-risk populations, validating FNP as both an assessment and intervention tool.
- FNP identifies modifiable biological risk factors for reactive aggression and provides defined forensic response pathways, with direct translational relevance for custodial settings and offender rehabilitation

Table 1. FNP Framework Domains, Indicators, and Composite Weightings

Domain	Key Indicators	Weight (%)
Nutritional Biomarkers	Omega-3 index (EPA+DHA); Vitamin D (25(OH)D); Ferritin; B-vitamins (B6, B9, B12); Zinc; Magnesium	40
Diet Quality	Ultra-processed food intake; total glycaemic load; fruit and vegetable frequency; dietary pattern scores (AHEI / DASH)	20
Stress & Physiology	Cortisol diurnal rhythm (AM/PM); C-reactive protein (CRP); sleep quality index	20
Behavioural Markers	Impulsivity scales (BIS-11); aggression inventories (Buss-Perry AQ); emotional regulation assessments (DERS)	20
Total Composite Score	**Nutrition + Diet Quality + Stress Load + Behavioural Indices**	**100**

Note. FNP = Forensic Nutrition Profiling; BIS-11 = Barratt Impulsiveness Scale version 11; AQ = Aggression Questionnaire; DERS = Difficulties in Emotion Regulation Scale; AHEI = Alternate Healthy Eating Index; DASH = Dietary Approaches to Stop Hypertension.

Table 2. FNP Proposed Biomarker Panel: Analytical Methods and Evidence Base

Biomarker	Sample Matrix	Analytical Method	Proposed Behavioural Correlate	Evidence Base
Omega-3 Index (EPA+DHA)	Erythrocytes	GC-MS / LC-MS	Impulsivity; affective dysregulation; reactive aggression	Hibbeln et al., 2006; Raine & Brodrick, 2024
Vitamin D (25(OH)D)	Serum/plasma	LC-MS/MS; ELISA	Irritability; mood instability; serotonin synthesis modulation	Anglin et al., 2013
Ferritin (Iron Status)	Serum	Immunoassay	Dopaminergic deficits; cognitive slowing; behavioural	Beard, 2008

Biomarker	Sample Matrix	Analytical Method	Proposed Behavioural Correlate	Evidence Base
			dysregulation	
B6, B9, B12 (B-Vitamins)	Plasma	HPLC; immunoassay	Serotonin and dopamine cofactor depletion; neurotransmitter impairment	Kennedy, 2016
Zinc	Serum/plasma	ICP-MS; atomic absorption	NMDA receptor dysfunction; synaptic inhibition deficits; aggression	Choy, 2023
Magnesium	Serum / RBC	Spectrophotometry	HPA axis hyperreactivity; emotional volatility under stress	Choy, 2023
Cortisol (AM/PM Diurnal)	Saliva	ELISA; LC-MS/MS	HPA dysregulation; stress-reactive aggression; impaired inhibition	McEwen, 2007
C-Reactive Protein (CRP)	Serum	High-sensitivity ELISA	Neuroinflammation; mood instability; frontal cortex hypoactivity	Miller et al., 2009
Tryptophan / Tyrosine	Plasma	HPLC; LC-MS	Precursor depletion for serotonin and dopamine synthesis	Benton, 2010
Glycaemic Index / Insulin	Serum	Immunoassay; glucose oxidase	Glycaemic instability; self-regulation failure; irritability	Benton, 2007

Note. GC-MS = Gas Chromatography–Mass Spectrometry; LC-MS = Liquid Chromatography–Mass Spectrometry; ICP-MS = Inductively Coupled Plasma Mass Spectrometry; HPLC = High-Performance Liquid Chromatography; ELISA = Enzyme-Linked Immunosorbent Assay; RBC = Red Blood Cells.

Table 3. FNP Composite Risk Score Matrix: Tier Classification, Clinical Interpretation, and Recommended Forensic Responses

Risk Level	Score	Biomarker Profile	Clinical Interpretation	Recommended Forensic Response
Low	0–24	Adequate across all domains	Minimal neurochemical vulnerability; baseline behavioural control maintained	Routine monitoring; no nutritional intervention indicated
Moderate	25–49	1–2 biomarker deficiencies; suboptimal diet quality	Elevated stress reactivity; mild impairment of impulse regulation under provocation	Dietary counselling; targeted micronutrient supplementation; re-assessment in 3 months
High	50–74	3–4 deficiencies; elevated CRP; poor diet quality	Significant neurochemical vulnerability; heightened susceptibility to reactive aggression	Clinical nutrition referral; omega-3 and micronutrient supplementation; psychoeducation
Critical	75–100	Multi-domain deficits; cortisol dysregulation;	Severe physiological risk milieu; high probability of	Multidisciplinary forensic–nutritional intervention;

Risk Level	Score	Biomarker Profile	Clinical Interpretation	Recommended Forensic Response
		systemic inflammation	aggression under minimal provocation	custodial dietary management

Note. Risk tier classification is based on weighted domain score aggregation. FNP scores are intended to inform, not replace, professional forensic judgement. Classification should be interpreted within the full psychosocial context of the individual case.

Table 4. Comparison of FNP with Established Forensic Risk Assessment Instruments

Instrument	Domains Assessed	Biomarkers	Nutrition	Physiology	Output
HCR-20 V3	Historical, clinical, risk management items	No	No	No	Structured professional judgement
VRAG-R	Actuarial (criminal & clinical history)	No	No	No	Risk score / bin classification
START	Dynamic psychosocial strengths & risks	No	No	Partial (substance use)	SPJ with treatment planning
PCL-R	Psychopathy trait measurement	No	No	No	Dimensional score
FNP (Proposed)	**Nutritional biomarkers, diet, physiology, behaviour**	**Yes**	**Yes**	**Yes**	**Composite risk score + intervention pathway**

Note. HCR-20 = Historical Clinical Risk Management; VRAG-R = Violence Risk Appraisal Guide-Revised; START = Short-Term Assessment of Risk and Treatability; PCL-R = Psychopathy Checklist-Revised; SPJ = Structured Professional Judgement. FNP is proposed as a complementary instrument, not a replacement for established tools.

ABSTRACT

Ipomoea hederifolia L. is a medicinal plant belonging to the family *Convolvulaceae.* This study investigates its phytochemical and elemental composition using Fourier Transform Infrared Spectroscopy (FTIR) and Inductively Coupled Plasma Mass Spectrometry (ICP-MS). FTIR analysis revealed characteristic absorption bands corresponding to hydroxyl, alkane, aromatic andphenolic functional groups, indicating the presence of important bioactive compounds. ICP-MS analysis detected essential trace elements such as iron, zinc, copper, manganese and nickel. These elements are known to play important roles in biological and metabolic processes. The scientific data generated by the combined analytical technique confirms the plant's therapeutic value and suggests its potential use in pharmaceutical and nutraceutical applications.

Keywords: *Ipomoea hederifolia* L., phytochemicals, ICP-MS. FTIR

INTRODUCTION

Medicinal plants have been an important source of medicinal compounds for thousands of years. A substantial number of current pharmaceutical medications are derived from natural sources, many of which were discovered through their traditional medical use. Natural compounds originating from plants continue to play a critical role in drug discovery and development due to their various chemical structures and biological activity. [1]. Plants contain

naturally occurring bioactive molecules known as phytochemicals, which have a substantial impact on human health. These substances include secondary metabolites such as alkaloids, flavonoids, phenolic, terpenoids, and glycosides, all of which have a wide range of pharmacological effects. In addition to their medicinal potential, phytochemicals are crucial macro and micronutrients that promote normal physiological processes in humans. [2].

India is regarded as one of the wealthiest countries in terms of biodiversity, with a huge range of plant species due to its varied climatic and geographical circumstances. Many of these plants have long been utilised in ancient medicinal systems such as Ayurveda, Unani, and folk medicine. Scientific validation of ethno-medicinal plants through phytochemical and pharmacological investigations is crucial to validate their safety, potency, and potential therapeutic value. [3]. Documenting ethno-botanical and ethno-pharmacological knowledge is thus vital for supporting future study in herbal therapy and facilitating its implementation in modern healthcare systems. [4]. *Convolvulaceae* is a plant family with over 1650 species, most of which are found in tropical locations across the world. Ipomoea is one of the larger genera in this family, with around 500-600 flowering plant species. [5]. This genus's species are generally known as morning glories because of the unique behaviour of their blooms, which open in the morning and close later in the day. Many varieties of *Ipomoea* are often grown as ornamental plants because of their gorgeous blooms and robust growth, but some are also considered weeds owing to their tendency to spread fast. [6].*Ipomoea hederifolia* L., a medicinal climbing plant in the *Convolvulaceae* family, is sometimes referred to as scarlet morning glory or scarlet creeper. The species *name hederifolia* comes from Latin and describes the vine's ivy-like leaves, while the genus name Ipomoea is derived from the Greek terms ips and homoios, alluding to the twining or worm-like growth behaviour of the vine. [7].

Due to its many medicinal uses, this plant has long been utilised in many medical systems. Diuretic, anthelmintic, laxative, carminative, blood-purifying, anti-inflammatory, and deobstructive properties are described. The herb has historically been used to cure a number of illnesses, such as bronchitis, fever, headaches, and stomach problems. [8]. The seeds are used in traditional Chinese medicine to treat ailments including constipation, oedema, and parasite infections because of its cathartic, diuretic, anti-inflammatory, and expectorant qualities. The plant is known to have sternutatory action in its roots. [9]. Traditional medicine has long acknowledged climbing plants as important sources of bioactive chemicals with possible medicinal uses. However, there are a number of obstacles to using these plants in contemporary pharmaceutical research, including as the large-scale manufacture of bioactive ingredients, the identification of active molecules by high-throughput screening, and the sustainable sourcing of plant materials. Despite these difficulties, climber plants are still widely used in traditional healthcare systems around the world, especially in rural and tribal communities where they are used to treat a variety of illnesses, including fever, inflammation, skin infections, respiratory disorders, digestive issues, and pain. Their ecological, therapeutic, and cultural relevance emphasises the value of ongoing study and conservation initiatives. [10]. Tropical and subtropical areas are home to the twining *vine Ipomoea hederifolia* L. Nearly 2000 species and 58 genera make up the family Convolvulaceae, which is primarily distinguished by herbaceous or woody plants with heart-shaped leaves, funnel-shaped blooms, and twining or climbing behaviours. With about 600 species worldwide, the genus Ipomoea is the biggest group in this family. [11].

METHODOLOGY

Impurities were removed from fresh *Ipomoea hederifolia*L.,plant material by washing it with distilled water. The plant material was shade dried and pulverised to a fine powder. Approximately 10 g of powdered material was extracted with ethanol by Soxhlet extraction. The extract was filtered and purified for future investigation. For FTIR analysis, a little quantity of dried extract was combined with Potassium bromide (KBr) and formed into a pellet. The spectra were collected from 4000-400 cmn^{1}. For ICP-MS analysis, the powdered plant sample was digested with strong nitric acid and hydrogen peroxide. The digested solution was diluted with deionised water and put into the ICP-MS apparatus to identify trace elements.

.

RESULTS AND DISCUSSION

FTIR Analysis Finding functional groups in organic compounds is a common use for FTIR spectroscopy. *Ipomoea hederifolia*L., FTIR spectrum showed a number of distinctive absorption peaks that suggested the existence of several phytochemical components.

- O–H stretching vibrations, which are typical of phenols and alcohols, are represented by the absorption peak seen at 3283 cm^{-1}. These substances are well known for their anti-inflammatory and antioxidant qualities. The peak at 2919 cm^{-1} represents C–H stretching vibrations linked to terpenoids and alkanes.
- Aromatic C=C stretching vibrations are shown by a significant peak at 1605 cm^{-1}, indicating the presence of phenolic chemicals and flavonoids. The C–O stretching vibrations of alcohols, esters, and carbohydrates are represented as peaks at 1241 cm^{-1} and 1054 cm^{-1}, which may be connected to glycosides and polysaccharide.
- Alkaloids and other aromatic phytochemicals may be represented by additional peaks about 779 cm^{-1} that show aromatic C–H bending vibrations. The fingerprint region contains the peak at 440 cm^{-1}, which might suggest the existence of metal–oxygen linkages connected to mineral elements.

These results validate that *Ipomoea hederifolia*L., contains a number of significant bioactive substances, including phenols, flavonoids, tannins, terpenoids, glycosides, carbohydrates, and alkaloids. These substances are known to have anticancer, anti-inflammatory, antioxidant, and antibacterial

FTIR Peak Interpretation

*Ipomoea hederifolia*L., contains various significant bioactive phytochemicals, including phenols, flavonoids, tannins, terpenoids, glycosides, polysaccharides, and alkaloids, according to its FTIR spectrum. These chemicals include antioxidant, antibacterial, anti-inflammatory, anticancer, and anti-diabetic activities, which contribute to the plant's traditional therapeutic use.

Elemental Analysis Using ICP-MS

ICP-MS analysis revealed the presence of several essential macro and trace elements in *Ipomoea hederifolia*L.

Major Elements

Major elements detected include potassium, sulphur, calcium, magnesium, phosphorus, iron, and sodium. Potassium showed the highest concentration among the major elements. These elements are essential for maintaining physiological functions such as nerve transmission, muscle contraction, bone formation, and energy metabolism.

Trace Elements

Trace elements detected include manganese, zinc, copper, boron, chromium, nickel, cobalt, and molybdenum. These elements play crucial roles in enzymatic reactions, immune system regulation, and metabolic processes.

Potentially Toxic Elements

ICP-MS analysis also detected trace amounts of potentially toxic elements such as lead, cadmium, arsenic, and mercury. However, the concentrations were extremely low and within permissible limits, suggesting that the plant is relatively safe for medicinal use. The presence of both macro and trace elements indicates the nutritional significance of *Ipomoea hederifolia*. These elements contribute to various biological functions including enzyme activation, oxygen transport, immune defence, and bone health.

The elemental analysis of *Ipomoea hederifolia* shows the presence of several essential macro and micro nutrients such as potassium, calcium, magnesium, phosphorus, iron, zinc, and manganese. These elements play important roles in human metabolism, bone health, enzymatic reactions, and immune function, indicating the potential nutritional and medicinal value of the plant. The extract's complete characterisation, together with good physical features, provides compelling proof of its effectiveness and safety in clinical applications [12].

CONCLUSION

The present study confirms that *Ipomoea hederifolia* contains significant phytochemical compounds and essential trace elements. FTIR analysis demonstrated the presence of functional groups associated with phenols, alcohols and aromatic compounds, while ICP-MS
revealed important micronutrients. The combined results highlight the medicinal and nutritional significance of the plant and support its traditional use in herbal medicine. Further research on isolation and pharmacological evaluation of the active compounds may lead to the development of new therapeutic agents.

Table 1: FTIR Peak Interpretation

Wavenumber (cm^{-1})	Functional Group	Possible Phytochemicals	Biological/Medicinal Significance
3283 cm^{-1}	O-H stretching can occur with alcohols, phenols	phenols, flavonoids, and tannins	Strong antioxidant, anti-inflammatory, and antibacterial; helps protect cells from oxidative damage
2919 cm^{-1}	C-H stretching in alkanes	terpenoids, lipids, and essential oils.	Contains antibacterial, antifungal, and anti-inflammatory effects.
1979 cm^{-1}	Weak overtone/combination. Band	Aromatic compounds	refer to complex organic phytochemicals used in plant defences

1605 cm^{-1}	C=C stretching in their aromatic rings	Flavonoids and phenolic compounds	Responsible for antioxidant, anticancer, and cardio protectiveactions
1412 cm^{-1}	O-H bending/C-C aromatic properties	Polyphenols and tannins exhibit	Anti-microbial, wound healing, and anti-ulcer properties
1241 cm^{-1}	C-O stretching (alcohols, phenols, esters)	Glycosides, Phenolic,and Esters	It has anti-diabetic, anti-inflammatory, and antibacterial properties.
1054 cm^{-1}	C-O stretching (carbohydrates/alcohols)	sugars, and polysaccharides	Contribute to energy metabolism, immunological support, and therapeutic properties.
1033 cm^{-1}	C-O stretching (alcohols and carbohydrates)	Glycosides and polysaccharides	Are associated with digestive and metabolic health advantages.
779 cm^{-1}	exhibit C-H bending.(Aromatic compounds,)	including alkaloids and phytochemicals,	May have analgesic and antibacterial effects.
440 cm^{-1}	metal-O bond / fingerprint region	Mineral complexes	Indicate the existence of trace elements necessary for biological activities.

Table 2: Major Elements and Their biological importance of Human Beings

S. No.	Element	Concentra-tion (mg)	Biological significance for Human Health
1	Potassium (K)	238.91 mg	Essential for neuron function, muscular contraction, and cardiac rhythm regulation
2	Sulphur (S)	158.42 mg	Crucial for the synthesis of proteins and the action of enzymes
3	Calcium (Ca)	124.62 mg	Required for bone and tooth development, blood clotting, and muscle contraction.
4	Magnesium (Mg)	41.28 mg,	Promotes muscular function, neuronal transmission, and energy generation
5	Phosphorus (P).	24.78.mg.	Necessary for cellular metabolism, DNA structure, and bone production.
6	Iron (Fe)	12.47 mg	Needed for blood oxygen transport and haemoglobin synthesis
7.	Sodium (Na)	6.32 mg	Maintains fluid balance and neuronal signalling

Table 3: Trace Elements and Their Importance to Human Beings

S. No.	Element	Concentration (mg/kg)	Importance for Human Health
1	Manganese (Mn)	2.16	Involved in bone formation and enzyme activation
2	Zinc (Zn)	1.2845	Supports immune system and wound healing
3	Copper (Cu)	0.7426	Helps in iron metabolism and red blood cell formation
4	Boron (B)	0.5631	Contributes to bone health and hormone regulation
5	Chromium (Cr)	0.173	Helps regulate blood glucose metabolism
6	Nickel (Ni)	0.0894	Plays a role in certain enzymatic reactions
7	Cobalt (Co)	0.0068	Component of Vitamin B12
8	Molybdenum (Mo)	0.0003	Essential for enzyme systems involved in metabolism

Table 4: Potentially Toxic Elements (Present in Very Low Amounts)

Element	Concentration (mg/kg)	Possible Effect
Lead (Pb)	0.0327	Toxic to nervous system if present in high concentration
Cadmium (Cd)	0.0013	Can damage kidneys and bones
Arsenic (As)	0.0031	Toxic in higher concentrations
Mercury (Hg)	0.0008	Harmful to brain and nervous system

ABSTRACT

This study assessed awareness and practice regarding biomedical waste management among housekeeping staff in SVBP Hospital Meerut, Uttar Pradesh, India. descriptive correlational design was used with 60 housekeeping staff selected through convenience sampling, and data were collected using a structured awareness questionnaire and an observational practice checklist. The tools showed acceptable internal consistency, with Cronbach's alpha values of 0.84 for awareness and 0.79 for practice. Most participants were male, aged 21 to 30 years, and had 0 to 5 years of work experience. More than half of the participants had moderate awareness, while a substantial proportion had poor practice. Pearson correlation showed a weak positive relationship between awareness and practice, and Fisher's exact test showed no significant association between awareness or practice and selected demographic variables . The study indicates a knowledge practice gap and supports the need for structured, hands-on training and regular supervision.

Keywords: correlational design, Cronbach's alpha values hands-on training and regular supervision.

INTRODUCTION

Biomedical waste management is a critical component of healthcare safety because improper handling can expose staff, patients, and the environment to infection and other hazards. In India, biomedical waste generation has

increased with the expansion of healthcare services, and compliance with Biomedical Waste Management Rules remains a challenge in many institutions. Housekeeping staff play a central role in segregation, collection, transport, and temporary storage of biomedical waste, yet they often receive limited formal training. This makes their awareness and daily practice especially important for safe hospital functioning. The present study was undertaken to assess awareness and practice regarding biomedical waste management among housekeeping staff in a selected hospital and to examine the relationship between these two variables. It also aimed to identify whether selected demographic variables were associated with awareness or practice levels.

METHODOLOGY

Study Design and Setting

Research Design: A Quantitative descriptive correlational design was utilized to explore the relationship between variables.

Study Setting: The research was conducted at a selected multi-specialty SVBP hospital located in Meerut, Uttar Pradesh, India.

Population and Sampling

Sample Size: A total of 60 housekeeping staff members participated in the study.

Sampling Technique: Convenience sampling (a non-probability sampling method) was used to select the participants.

Inclusion Criteria

- Minimum of 6 months of work experience in the current setting.
- Direct involvement in the handling of biomedical waste.
- Willingness to participate in the study.
- Proficiency in understanding Hindi or English.

Data Collection Tools

Data was gathered using three specific instruments:
Socio-demographic Proforma: To collect baseline characteristics of the participants.
Structured Awareness Questionnaire: To assess the level of awareness regarding biomedical waste management.
Observational Checklist: To evaluate the actual practices followed by the staff.

Validity and Reliability

Content Validity: Tools were validated by a panel of subject matter experts.
Reliability: Following a pilot study, internal consistency was confirmed using Cronbach's alpha:
Awareness Tool: r = 0.84 (Highly reliable).
Practice Tool: r = 0.79 (Reliable).

Data Analysis Plan

The collected data were analyzed using both descriptive and inferential statistics:
Descriptive Statistics: Frequency, percentage, mean, and standard deviation (SD).
Inferential Statistics:
Pearson Correlation Coefficient: To determine the relationship between awareness and practice.
Fisher's Exact Test: To associate demographic variables with awareness and practice score.

RESULTS

The sample was predominantly male, with 71.66 % males and 28.33 % females. Most participants were aged 21 to 30 years, and 76.67 % had 0 to 5 years of work experience. Regarding training, 56.67 % reported annual training, while 18.33 % had no prior training. For awareness, 51.67 % of participants had moderate awareness, 36.67 % had poor awareness, and 11.67 % had good awareness. The mean awareness score was 11.43 with a standard deviation of 3.44. For practice, 45.00 % had poor practice, 36.70 % had moderate practice, and 18.30 % had good practice. The mean practice score was 30.08 with a standard deviation of 9.47. Pearson correlation analysis showed a weak positive relationship between awareness and practice, with [r = 0.242] . Fisher's exact test showed no significant association between awareness and demographic variables or between practice and demographic variables, as all reported p-values were greater than 0.05.

DISCUSSION

The findings suggest that housekeeping staff had a basic level of understanding, but this did not consistently translate into good operational practice. The weak correlation between awareness and practice indicates that knowledge alone is not sufficient to ensure adherence to correct biomedical waste procedures. This may reflect the influence of supervision, workload, availability of protective equipment, and institutional enforcement. The demographic profile of the sample also suggests a young and relatively inexperienced workforce, which may benefit from repeated orientation and competency-based training. The lack of significant association between awareness or practice and demographic variables implies that performance may depend more on workplace systems than on personal background characteristics. This supports the need for standardized hospital protocols, monitoring, and routine reinforcement.

CONCLUSION

The study concludes that housekeeping staff in the selected hospital had moderate awareness but weaker practice regarding biomedical waste management. A knowledge practice gap was evident, and the relationship between awareness and practice was weak. Demographic variables did not show significant association with either awareness or practice. Institutional training, supervision, and enforcement appear essential to improve compliance and promote safer biomedical waste management.

ACKNOWLEDGMENT

The authors express sincere gratitude to the Principal, guide, faculty members, and participants for their support and cooperation in completing this study.

ABSTRACT

Fasting permits the essential energy to draw out toxins from the blood and rejuvenate the system. Many people today have very unfit, passive lifestyles devoid of such physical exercises. A sedentary way of life and eating three meals a day (breakfast, lunch, supper, and snacks in between) commonly result in physiological morbidity that leads to a wide range of diseases that many are unaware of. In these scenarios, the notion of Intermittent Fasting acquired widespread acceptance worldwide. Fasting includes two windows: fasting and feasting with specific meal timings and options in both periods that help generate maximum health benefits by activating the several mechanisms that occur inside the body during fasting. The long-term effect of these mechanisms progresses toward inhibiting the morbidity and other ill effects of a sedentary lifestyle. It is also believed that a systematic and time-restricted regimen may reduce some of the ill effects of this practice, including dizziness, weakness, etc. This review provides current literature on several intermittent fasting regimens, the mechanism behind their influence on body metabolism, and the promising health outcomes of this practice along with the possible hazards of it.

Keywords: Metabolic, oxidative, Cognitive, Diet regimen and Health

INTRODUCTION

After a carbohydrate-containing meal, energy is stored as glucose in the liver, and any excess is stored in the body's fat reserves. The liver can store around 400-500 calories of glucose, while fat can store much more. This stored fat provides energy for extended fasting periods. Intermittent fasting requires fasting for at least 12 hours to shift the body from using glucose to utilizing ketones produced by fat (Mattson, 2023). Intermittent fasting is frequently misunderstood as a diet by the general public and media, although it is an eating pattern rather than a prescriptive diet. It involves prolonged periods of reduced or negligible energy intake, typically lasting around 16-8 hours, interspersed with regular food consumption during specific time frames (Nain et al., 2020). This diet doesn't require people to completely change their current eating habits or replace everything in their kitchen. Also, intermittent fasting doesn't require individuals to avoid food groups or specific macronutrients, nor does it require participants to closely monitor their daily calories (Varady et al., 2021). Despite the increasing prevalence of intermittent fasting, there is limited research on the potential health benefits of these dietary patterns in human subjects. Preliminary evidence suggests that intermittent fasting may have a positive impact on weight management and metabolic health by reducing oxidative stress, increasing stress resistance, enhancing glucose metabolism, and attenuating inflammation (Chaix et al., 2019).

Fasting regimens affect metabolic rates by influencing many physiological mechanisms like the circadian clock, gut microbiota, and modifiable lifestyle habits such as sleep. Studies have shown that it can reduce systemic inflammation and play a role in preventing illness and managing chronic diseases (Nain et al., 2020). Beyond weight loss due to calorie restriction, there are many more beneficial health effects of intermittent fasting. Common intermittent fasting patterns include daily time-restricted eating (e.g., 16/8) or 2 to 4 non-consecutive full-day fasts per week. On fasting days, certain regimens permit very low-calorie intake (500-700) (Patterson et al.,2017). The majority of intermittent fasting interventions fall into three broad types. Alternate day fasting (ADF) programs usually include a "festival" on which food is consumed selectively, or practicing a "fasting day" on which no food is eaten or decreased followed by a feasting day (Tinsley et., 2015). Whole-day fasting (WDF) is typically defined as one to two non-consecutive full fasting days per week, with the remainder of the time spent eating freely. Time-restricted feeding (TRF) occurs when food consumption is restricted to a specified period of day while fasting the rest of the time including 16:8 hours fasting or 10:14 hours fasting patterns (Longo et al., 2016). Although intermittent fasting can take several forms, studies have shown that it is a sustainable and simple lifestyle with numerous health benefits. Fasting has been thought of as a beneficial technique for treating overweight and comorbid individuals since the 1960s, with additional benefits discovered more recently (Wilhelmi et al., 2020). IF has reached incredible public prominence in recent years due to media coverage; however, it is vital to emphasise that it has been engaged in for decades for wellness and spiritual reasons, including as during the month of Ramadan (Vitale et al., 2020). Diet has a major impact on the gut microbiota, which is an additional link between nutrition and immune-inflammatory responses. Calorie restriction also has potent anti-inflammatory properties. Through impacts on the intestinal microbiota, IF is demonstrated to be a protective factor in the animal model of multiple sclerosis. Patients with relapsing metabolic syndrome who undertake brief intermittent fasting also exhibit similar alterations in their gut microbiota (Cignarella et al., 2018).

Mechanism Behind IF

To comprehend the metabolic impact of this practice, three primary concepts have been stated and represented in Fig.3: (i) the Ketosis principle, (ii) the oxidative stress speculation, and (iii) the circadian biology hypothesis (Fig.2). Upon a meal, glucose is used for energy or deposited as glycogen or triglyceride. Fasting causes the liver's glycogen stores to be utilized. As the liver's glycogen stores deplete (after 8-12 hours of water-only fasting), it begins building ketones, such as ß-hydroxybutyrate (BHB) and acetoacetate, to provide an energy source for the tissues around the body for 48 hours of fasting, blood BHB levels may rise and continue to increase. BHB acts as a metabolic intermediary and a signaling molecule that regulates metabolism in response to dietary restriction and modifies cellular processes and signaling pathways associated with aging and human diseases (Newman et al., 2017). So,

according to the ketosis theory, lower calorie consumption induces an alteration in metabolic state that results in accelerated fat metabolism and lower buildup of fat. The theory reinforces immediate impacts such as weight loss, waist circumference reduction, and improved fat percentage (Rojas-Morales et al., 2016). It has been shown that intermittent fasting (IF) produces positive outcomes comparable to calorie restriction, such as decreased oxidative stress. Oxidative stress is an essential consequence of interest concerning obesity because it can exacerbate or accelerate the development of metabolic-related problems (Mohr et al., 2021). The oxidative stress concept reveals that lower calorie consumption and formation of volatile species by the mitochondria lead to a reduced cellular inflammatory process (Dong et al., 2020). (Mo'ez Al-Islam et al., 2019) the study suggested that diurnal intermittent fasting during Ramadan may reduce oxidative stress and low-grade systemic inflammation in healthy individuals, potentially mitigating negative health effects.

Meals consumed at an appropriate time for the body's circadian clock to ensure that the interactions between fasting, mealtimes, and sleep do not negatively impact the circadian rhythm of various body organs and cells (Almeneessier et al., 2018). Intermittent fasting (IF) is a historically recognized practice implemented in diverse manners by global communities, involving voluntary abstinence from food for predetermined intervals (Patterson et al., 2017). According to certain animal research, regulating meal times and limiting food intake can effectively align peripheral tissues' biological clocks with a set exposure to the light-dark cycle (Mongrain et al., 2005). Furthermore, it has been found that mealtime routines in several animals can cause the stimulation of brain circadian clock genes, which are thought to be regulated by a "food-regulated clock." (Patton DF et al., 2013). Several human studies show that restricted eating improves the cardiometabolic health of those who are overweight or obese especially valid when the period for food consumption is at the start of the day and when fasting is towards the final stage of the active biological phase (Queiroz et al., 2021).

Impact on Health And Beyond

In animal research, calorie restriction is related to improved health, greater lifespan, and a reduction in morbidity and death. Calorie reduction improves cardiovascular health, weight loss, insulin sensitivity, diabetes control, cognitive function, and cancer prevention, among other benefits. Intermittent fasting minimizes the risk of malnutrition, is easier to implement, and is gaining recognition among healthcare providers (Golbidi et al., 2017).
Some of the mechanical perspectives of the regimen on health and other factors are addressed in Fig. 4.

Intestinal Microbiota

Disorders related to metabolism and other diseases such as insulin resistance, cardiac diseases, irritable bowel syndrome, and various malignancies including colorectal and breast carcinoma are the major reasons for the increasing mortality rate worldwide (Rajilić-Stojanović et al., 2014). Since the intestinal microbiome of healthy people is highly diversified and that of unwell people is peculiar and less diverse, the diversity and composition of the gut microbiota have been shown to play a significant role in metabolic disorders. (Harmsen et al., 2016). Similar to how medications destroy both infections and beneficial bacteria, probiotic strains also find it difficult to survive in the gut for extended periods. Additionally, the effects of prebiotic products are not particular (Druart et al., 2014). Some studies conclude that intermittent calorie restriction has been shown to activate brown adipose tissue in rats and improve obesity by probably altering the gut microbiome's composition (Li et al., 2017). As a result, it has gained acceptance as a weight loss and metabolism-boosting method all around the world. This strategy might promote the growth of microbial communities that boost thermogenesis-related metabolism (Mattson et al., 2017).

Carcinogenesis Inhibition

Although it might be challenging to maintain, research in preclinical and clinical settings has shown that prolonged calorie limitation has significant anticarcinogenic effects. Because of promising study results, mostly in experimental animal models, intermittent fasting has developed acceptance as a substitute for continuous fasting in both the scientific and ordinary communities (Clifton et al., 2021). According to preliminary research, long-term fasting could be safe and effective in reducing the toxicity and proliferation of tumors associated with radiotherapy in certain cancer patients. A study suggests lower risk of all female-specific malignancies, such as gynecologic and breast

cancers, was linked to the decline in cancer incidence (Anveden et al., 2017). After a median of 20 years of follow-up, a Swedish study comparing patients who had bariatric surgery with a control group discovered a 29% reduction in cancer incidence and a 23% reduced cancer mortality (Carlsson et al., 2020). It is thought that circadian rhythm abnormalities contribute to carcinogenesis by altering the expression of genes related to metabolism, autophagy, and DNA damage repair (Sulli et al., 2019). A study performed on intermittent fasting practice in mice has concluded that circadian rhythms were reset by this practice which is followed by gene alteration to inhibit carcinogenesis. However, the time of feeding was a dependent variable (Froy et al., 2009).

Aging and Cognition

The main risk variable for neurological illness is aging, which becomes worse by sedentary lifestyles as well as elevated intake of calories. It has been demonstrated that some traditional eating practices, including intermittent fasting (IF), extend life expectancy and improve health through an adaptive stress response (Seidler et al., 2022). In addition to medical treatments that did not show promise in reversing cognitive loss and advancing the disease, dietary interventions such as calorie restriction and intermittent fasting have been shown to enhance longevity as well as health in a range of species, with preliminary data from human trials supporting this claim (Anton et al., 2021).

Regulation of Blood Glucose

Hyperglycemia, a prevalent metabolic condition known as type 2 diabetes mellitus has several causes such as reduced glucose utilization, hepatic glucose synthesis that is excessive, insulin resistance, impaired insulin secretion, and systemic low-grade inflammation (Powers et al., 2018). A growing number of research is showing the short-to-medium-term effects of intermittent fasting on glucose and lipid homeostasis (Antoni et al., 2017). In a recent experiment, an intermittent fasting diet enhanced insulin tolerance without significantly altering body mass index, even when the calories delivered were identical to those of the control group. This demonstrates that fasting practice alone can improve glucose metabolism without requiring changes in body weight (Sutton et al., 2018).

Promotion of Weight Loss

Consuming high-energy foods and being sedentary can lead to obesity, a major health issue globally. Recent studies suggest that diets emphasizing intermittent fasting may aid in weight loss and improve human health (Erdem et al., 2022). Weight control programs typically employ a 20% to 40% daily calorie restriction to achieve the negative energy balance needed for weight loss. However, intermittent fasting or intermittent calorie restriction is gaining attention as an alternative strategy (Freire et al., 2020). In the study, intermittent fasting led to a 53% decrease in energy intake compared to a 72% reduction with daily calorie restriction. Additionally, intermittent fasting resulted in an 8.8% decrease in body mass, while daily calorie restriction led to a 6.2% decrease. Both groups experienced similar reductions in fat and lean mass and improved fasting lipid profiles (Catenacci et al., 2016).

Cardiovascular Effect

Atherosclerotic cardiovascular disease and myocardial infarction are significantly increased by low HDL cholesterol levels and elevated levels of circulating LDL cholesterol and triglycerides (Liou et al., 2020). In a study (Wilkinson et al., 2020), 12-week 10-hour time-restricted eating reduced the LDL cholesterol concentrations of participants with metabolic syndrome compared to baseline. In contrast, in every other research (Sutton et al., 2018), that looked at this measure, LDL cholesterol concentrations stayed constant in comparison to controls. According to the results, of the study, TRE appears to be a safe diet therapy that helps obese individuals lose a small amount of body weight while simultaneously lowering numerous important cardiovascular disease indicators (Gabel et al., 2021). Almost all IF trials have resulted in weight reduction ranging from 2.5-9.9% and accompanying fat mass decrease (Byrne et al., 2018). While most research found that weight and fat mass reduced, In IF treatments, it is critical to assess protocol adherence and dropout rates. According to certain research, the ADF (Alternate day fasting) group ate more than usual on fasting days and less than usual on feast days (Trepanowski et al.,2017). According to research, IER has been linked to improvements in beta cell function and insulin resistance in mouse models. There are two primary processes, one derived from the autophagy-lysosome pathway and the other from increased neurogenin3 (Ngn3)

levels (a marker for endocrine progenitor cells resembling cells throughout development). The drop in insulin levels recorded in people counters the rise observed in mice, suggesting that the key cause in humans is an improvement in peripheral insulin action (Muñoz - Hernández et al., 2020). Notably, IER stimulates gut microbiota regeneration. An increase in HDL cholesterol levels is also commonly noted (Arnason et al., 2017). According to a metabolic study where regular-IF group had a substantial increase in superoxide dismutase (SOD) activity as well as a reduction in body weight, insulin, fasting blood glucose, malondialdehyde (MDA), C-reactive protein (CRP), and DNA damage, it is concluded that IF may alter cognitive performance via a variety of metabolic pathways, including ketone body production and degradation, butanoate metabolism, pyruvate metabolism, and glycolysis and gluconeogenesis (Ooi et al., 2020).

Possible Hazards and Repercussions of Intermittent Fasting

This type of fasting may sometimes lead to hunger, weakness, headaches, dehydration, dizziness, difficulty concentrating, low blood pressure, etc. To ensure management of one's nutritional needs with fasting practices a nutritionist or dietician must be consulted. Some people are advised to avoid this practice of fasting which includes children below 18 years, pregnant or nursing mothers, elder people, and people with certain eating disorders. People with weak immune systems, and diabetes (hypoglycemia) are also advised to have a word with their doctor before attempting this eating regimen (Li et al., 2021).

CONCLUSION

Intermittent fasting is a natural dietary-based practice that allows calorie restriction for specific time intervals. The method of adaptation may vary depending on the severity of the disorder and nutritional requirements. The regimen can result in various side effects like dizziness & weakness etc. to persons below the age of 18. The right conduct to the process including the choice of regimen based on set goals & practicing under guidance can prevent many lifestyle disorders and promote healthy well-being.

Availability of data and materials

The data mentioned was thoroughly analyzed and reported in this work in the form of references.

Declaration of conflicting interests

The author(s) declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Funding

The author(s) received no financial support for the research, authorship, and/or publication of this article.

ABSTRACT

The present investigation evaluates the analgesic activity and central nervous system (CNS) stimulant activity of the hydroalcoholic extract of *Cedrus deodara* leaves in Albino Wistar rats. The extract was prepared using Soxhlet extraction with 70% ethanol. Analgesic effects were examined through the tail flick method, while motor coordination and CNS stimulation were assessed using the rotarod apparatus. In the tail flick test, the standard drug group showed the highest withdrawal latency (4.20–5.17 seconds), followed closely by the extract-treated group (4.15–5.10 seconds), both significantly higher than the control group (3.57–4.60 seconds), indicating meaningful analgesic activity of the extract. Similarly, in the rotarod evaluation, the extract-treated group demonstrated enhanced performance with an average time of 102 seconds, which was comparable to the standard (108 seconds) and markedly superior to the control group (48 seconds). These observations suggest that the hydroalcoholic extract of *Cedrus deodara* possesses moderate analgesic potential along with notable CNS stimulant activity. Further phytochemical and mechanistic studies are recommended to identify the active components responsible for these pharmacological effects.

Keywords: *Cedrus deodara*, Hydroalcoholic extract, Analgesic activity, CNS stimulant activity.

INTRODUCTION

Medicinal plants have long been recognized as important sources for discovering new therapeutic agents, with approximately 80% of individuals in developing countries relying on traditional medicine derived from plants.[1] Historically, the use of medicinal plants was based on empirical knowledge, but over time scientific explanations of their therapeutic uses have emerged. Despite advancements in synthetic drugs, limitations such as reduced efficacy and side effects make natural products an attractive alternative once again.[1] Several plants contain bioactive compounds with anti-analgesic and central nervous system (CNS) stimulant properties. For example, Aconitum species contain alkaloids used traditionally for analgesic and anti-inflammatory purposes.[2] Aloe vera has also been used for various therapeutic applications but requires caution due to some potential adverse effects.[3] Other medicinal plants, such as Ginkgo biloba, have been reported to improve cognitive function but may increase bleeding risk with long-term use.[4]*Cedrus deodara* (Deodar cedar), native to the western Himalayas, is a large evergreen tree valued both for its durable timber and its medicinal properties.[5] It has been traditionally utilized in Ayurvedic medicine for treating fever, pulmonary complaints, urinary disorders, and as an anti-inflammatory agent.[6,7]Studies have demonstrated that volatile oils from *Cedrus deodara* exhibit significant analgesic, anti-inflammatory, and antibacterial activities.[6,7] Additionally, alcoholic extracts of its heartwood have shown anxiolytic and anticonvulsant effects in rodent models, suggesting CNS activity.[8] Given this background, *Cedrus deodara* represents a promising candidate for further pharmacological evaluation regarding its anti-analgesic and CNS stimulant potential. Such investigations may help validate traditional uses and contribute to developing novel phytopharmaceuticals with improved safety and efficacy profiles.[9]

METHODS

Method of Extraction: [8,9,10]

Fresh *Cedrus deodara* leaves were collected, washed thoroughly with tap water, and air-dried at room temperature for 10–12 days. The dried leaves were chopped into small pieces, and 15 grams were weighed and packed in butter paper. The sample was then placed in a soxhlation apparatus, and 150 ml of 70% ethanol was added. Extraction proceeded for 72 hours with regular monitoring of water flow every 15 minutes. The extract was collected in a beaker, cooled at room temperature, and then sterilized in an autoclave at 121°C and 15 psi for 15 minutes. The solvent was evaporated over 10–12 hours to concentrate the extract, which was cooled, autoclaved again, and refrigerated until use.

Dose Calculation: [4]

The human therapeutic dose of Aceclofenac, 100 mg for a 70 kg adult, was taken as the reference for determining the equivalent dose for rats weighing 150–200 g. Using body-surface-area conversion, this human dose was scaled down to obtain the corresponding rat dose, which was calculated to be approximately 1.5–2.0 mg per animal. For experimental administration, the drug solution was prepared such that 5 mg of aceclofenac was dissolved in 1mL of distilled water, allowing the required dose to be accurately delivered in a suitable volume for the rats.

Experimental Methods:

Anti-Analgesic Activity: Tail Flick Method

Male Albino Wistar rats weighing between 150–200 g were selected for the study. The animals were randomly divided into three groups, with six rats in each group, Different groups of animals received their respective doses through the oral route.

Group I – Control: These rats did not receive any treatment.

Group II – Standard: Rats in this group received Aceclofenac (10mg/kg).

Group III – Sample: Rats in this group were administered the *Cedrus deodara* extract (250mg/kg).

To assess analgesic activity, the basal reaction time of each rat was measured using the tail-flick method. The tip of the tail (1–2 cm) was gently immersed in hot water maintained at 55 ± 2°C, and the time taken by the rat to withdraw its tail was recorded. Under normal conditions, rats respond within 3–5 seconds. Animals that failed to withdraw their tails within this range were excluded to avoid abnormal response bias. A cut-off time of 10–12 seconds was used to prevent tissue injury. After administration of Aceclofenac or test extract, the reaction time was monitored at 15-minute intervals initially to ensure the animals were responding normally. Subsequently, tail-flick latencies were recorded at 15, 30, 60, 90, and 120 minutes post-treatment. A reaction time of 10 seconds was considered the point of maximum analgesia, and the tail was immediately removed from the heat source to prevent damage.

CNS Stimulant Activity: Rota-Rod Method

Albino Wistar rats weighing 150–200 g were selected for the experiment. All animals were housed under standard laboratory conditions, maintained on a 12-hour light/12-hour dark cycle with free access to food and water.

The rats were then randomly divided into three groups, with six animals in each group:

Group I – Control: These animals did not receive any treatment.

Group II – Standard: Rats in this group were administered caffeine at 20 mg/kg through the oral route.

Group III – Sample: Rats in this group were treated with the *Cedrus deodara* extract at 250mg/kg through oral route.

RESULTS AND DISCUSSION

Result of analgesic activity

In the case of tail-flick technique, the control group had lesser time of tail withdrawal latency, meaning that there is an intact nociception mechanism. However, in the case of Aceclofenac (10mg/kg), the increase in the time of tail withdrawal indicates presence of a potent analgesia mechanism. The same was observed in the group administered with *Cedrus deodara*(250mg/kg) (Table 1, Figure 1, Figure 2, Figure 3, Figure 4, and Figure 5). In the rotarod experiment, the falling time in the control group was 48 ± 1.10 seconds. On the other hand, the falling time in the group given caffeine (20 mg/kg) increased significantly to 108 ± 0.55 seconds. Also, the falling time in the group given *Cedrus deodara* extract (250 mg/kg) increased to 102 ± 0.68 seconds (Table 2, Figure 6). The extract was collected using the Soxhlet extraction procedure, which is a common continuous hot extraction method employed in the isolation of bioactive components from plant samples. The extraction resulted in the production of a clean sample, which showed an average yield of 11%. The produced extract was then tested for its analgesic and central nervous system (CNS) effects on experimental rats.

In the test for analgesic effects, it was observed that the treated group took a relatively long time to withdraw their tails when placed in hot water compared to the control and standard groups. Such behaviour indicates an enhanced threshold of pain tolerance by the treated rats due to reduced sensitivity to the heat stimulus. The result implies that the extract has substantial analgesic properties. Moreover, motor coordination and neuromuscular performance were assessed by means of rota-rod device. The treated animals demonstrated increased grip strength ability to stay on the rota-rod for a more prolonged period of time compared to the control group. Increased ability to successfully perform on rota-rod test implies that the plant extract could stimulate motor coordination, neuromuscular performance, and the activity of central nervous system while not impairing motor function significantly. Overall, the discussed research data imply that the plant extract is likely to possess analgesic and CNS stimulant capabilities.

CONCLUSION

In this study, dried leaves of the selected plant were collected, and their extract was administered to experimental rats. Analgesic efficacy was assessed using the tail flick method, while CNS stimulant activity was evaluated through the rota-rod test. The findings indicate that the constituents of the extract exert a significant analgesic effect, comparable to that of the standard drug aspirin. However, due to the presence of multiple bioactive compounds in

the extract, the exact mechanisms and active agents responsible for analgesic action require further investigation. Additionally, the extract demonstrated stimulatory effects on the central nervous system, suggesting the involvement of substances distinct from caffeine that contribute to enhanced CNS activity. Consequently, further research is recommended to isolate and characterize these components to develop effective herbal therapeutics capable of providing both analgesic and CNS stimulation benefits.

ACKNOWLEDGEMENT

We would like to extend our sincere gratitude to Dr. Arnab Samanta, the principal of the Netaji Subhas Chandra Bose Institute of Pharmacy. We also appreciate the support from our friends, family, and all of the lab participants.

ABSTRACT

Queuing theory plays an important role in evaluating congestion, waiting time, and service performance in various real-life sectors including healthcare, banking, transportation, manufacturing, telecommunication, and cloud computing systems. Conventional queuing models generally assume exact arrival and service rates; however, such assumptions are often impractical in uncertain and rapidly changing service environments. To overcome this limitation, the present study develops an advanced dodecagonal fuzzy multi-server $M/M/c$queuing framework for intelligent service system optimization under uncertainty. The proposed model combines higher-order fuzzy numbers, Mamdani fuzzy inference mechanisms, and centroid defuzzification techniques to enhance the accuracy and adaptability of queue performance analysis. Dodecagonal fuzzy numbers are employed to represent uncertain arrival and service parameters because they provide smoother membership functions and more precise approximation than traditional triangular and trapezoidal fuzzy numbers. The framework evaluates major queuing performance measures such as server utilization, queue length, waiting time, idle probability, and system occupancy. Computational analysis of a three-server system demonstrates that the proposed methodology significantly reduces congestion and customer waiting time while improving

service efficiency and resource utilization. Mamdani fuzzy inference supports intelligent congestion analysis through linguistic IF–THEN rules, whereas centroid defuzzification converts fuzzy outputs into crisp values for practical decision-making. The findings indicate that higher-order fuzzy queuing models offer more realistic and efficient solutions for uncertain service environments and contribute significantly to intelligent fuzzy queuing theory and adaptive service optimization.

Keywords: Fuzzy Queuing Theory, Dodecagonal Fuzzy Numbers, Multi-Server M/M/cModel, Mamdani Fuzzy Inference System, Intelligent Service System Optimization

INTRODUCTION

Queuing theory is an important branch of Operations Research that studies waiting-line systems, congestion, customer arrivals, service mechanisms, and server utilization in various service environments. It has extensive applications in healthcare, banking, transportation, manufacturing, telecommunication, and cloud computing systems where efficient resource allocation and service optimization are essential. Among the classical queuing structures, the multi-server $M/M/c$model is widely used for systems where multiple servers operate simultaneously. In this model, arrivals follow a Poisson process, service times are exponentially distributed, and several parallel servers provide service to customers. Although the $M/M/c$model is highly applicable in hospitals, airports, call centres, and communication networks, it assumes precise arrival and service rates, which is often unrealistic in uncertain and dynamic real-life environments. To overcome this limitation, fuzzy set theory has been integrated into queuing analysis to handle uncertainty and vagueness more effectively. In fuzzy queuing systems, uncertain parameters are represented using fuzzy numbers rather than crisp values. Initially, triangular and trapezoidal fuzzy numbers were commonly used; however, they often fail to represent complex uncertainty accurately. Consequently, higher-order fuzzy numbers, particularly dodecagonal fuzzy numbers, have gained attention because of their twelve-parameter structure, smoother membership transitions, and improved precision. The integration of dodecagonal fuzzy numbers into the $M/M/c$framework enables better estimation of queue length, waiting time, congestion level, and server utilization under uncertainty. Furthermore, fuzzy inference systems such as Mamdani and Sugeno approaches improve adaptive decision-making and intelligent service optimization, while centroid defuzzification converts fuzzy outputs into crisp actionable measures. Therefore, dodecagonal fuzzy multi-server queuing models provide an advanced and realistic framework for intelligent service system optimization in uncertain environments.

REVIEW OF LITERATURE

Queuing theory is one of the most significant analytical and mathematical tools used for studying waiting-line systems, congestion phenomena, customer arrivals, service mechanisms, and server performance in modern service environments. The theory mainly focuses on analysing situations where the demand for service exceeds the available service capacity, leading to waiting lines and congestion. The origin of queuing theory can be traced to the pioneering work of A. K. Erlang, who developed probabilistic models to study telephone traffic congestion during the early twentieth century. Erlang introduced important performance measures such as waiting probability, traffic intensity, and service efficiency, which later formed the foundation of modern queuing analysis. Over time, queuing theory expanded considerably through the contributions of researchers such as Leonard Kleinrock, whose studies on communication networks and packet-switching systems demonstrated the practical importance of multi-server service systems in large-scale environments. Similarly, Donald Gross and John F. Shortle developed comprehensive mathematical formulations for classical queuing structures including $M/M/1$, $M/M/c$, finite-capacity queues, and priority queuing systems. Their work enabled the application of queuing theory in various fields such as healthcare management, transportation systems, banking services, manufacturing industries, computer communication networks, and cloud computing environments.

Among the classical queuing structures, the multi-server $M/M/c$ queuing model gained considerable importance because of its practical applicability in systems where multiple servers operate simultaneously to provide service. In the $M/M/c$model, customer arrivals follow a Poisson process, service times are exponentially distributed, and $c$parallel servers provide service to incoming customers. This model is widely utilized in hospitals, airports, call centers, telecommunication systems, production units, and banking systems for reducing congestion and improving service efficiency. Despite its wide applicability, the traditional $M/M/c$queuing model assumes that arrival rates and service rates are known precisely. However, practical service environments are generally characterized by uncertainty, fluctuating customer behavior, incomplete information, and variable service conditions. In real-life situations, customer arrivals and service efficiencies cannot always be represented by exact numerical values. Consequently, classical crisp queuing models often fail to capture the uncertain and dynamic nature of practical service systems.

To overcome these limitations, researchers incorporated fuzzy set theory into queuing analysis to develop fuzzy queuing models capable of handling uncertainty and vagueness more effectively. A major advancement in this direction was achieved through the introduction of fuzzy set theory by Lotfi A. Zadeh in 1965. Zadeh proposed that uncertain and imprecise information could be represented mathematically through membership functions instead of precise numerical values. This revolutionary concept transformed several areas of applied mathematics, engineering, optimization, and decision sciences by enabling the modelling of linguistic and approximate information. The integration of fuzzy set theory with queuing systems led to the development of fuzzy queuing theory, which provides a more realistic framework for analysing uncertain service environments. Early studies in fuzzy queuing were conducted by researchers such as R. J. Li, who introduced fuzzy arrival and service rates into queuing models and demonstrated that fuzzy numbers can effectively represent uncertain traffic intensity and service variability. Later, J. J. Buckley extended fuzzy queuing models by applying fuzzy arithmetic to determine waiting times and queue lengths under uncertain conditions. Similarly, S. Abbasbandy contributed significantly to fuzzy arithmetic, ranking methods, and computational approaches for solving fuzzy queuing problems, while H. J. Zimmermann introduced fuzzy optimization techniques that later became essential for intelligent queue management and adaptive decision-making in service systems.

Initially, most fuzzy queuing studies utilized triangular and trapezoidal fuzzy numbers because of their computational simplicity and ease of implementation. However, researchers later observed that these lower-order fuzzy numbers are often insufficient for representing highly dynamic and complex uncertainty patterns present in large-scale service systems. As a result, higher-order fuzzy numbers such as pentagonal, hexagonal, octagonal, decagonal, and dodecagonal fuzzy numbers gained increasing attention for improving modelling accuracy and reducing information loss. Among these, dodecagonal fuzzy numbers emerged as one of the most effective higher-order fuzzy representations because they consist of twelve parameters that allow smoother and more gradual membership transitions. Compared with triangular and trapezoidal fuzzy numbers, dodecagonal fuzzy numbers provide greater flexibility, improved sensitivity, and better approximation of uncertain arrival rates, service rates, and congestion levels. Their smooth membership distribution enables more accurate estimation of queue performance measures and more stable fuzzy outputs in uncertain service environments.

Another major advancement in fuzzy system research was the development of fuzzy inference mechanisms for intelligent control and adaptive decision-making. Ebrahim Mamdani introduced the Mamdani fuzzy inference system based on linguistic IF–THEN rules, which became highly useful in industrial automation, traffic management, and intelligent service systems. Similarly, Takagi Sugeno developed the Sugeno fuzzy inference model, which improved computational efficiency and optimization capability in real-time applications. The integration of Mamdani and Sugeno inference systems with fuzzy queuing models significantly enhanced adaptive queue management, server allocation, congestion control, and resource utilization. Furthermore, defuzzification techniques such as the centroid method became essential for converting fuzzy outputs into crisp actionable values suitable for practical decision-making. Although substantial progress has been made in fuzzy queuing theory, research involving dodecagonal fuzzy numbers integrated with multi-server $M/M/c$systems and fuzzy inference mechanisms remains

comparatively limited. Therefore, the present study focuses on developing an advanced dodecagonal fuzzy multi-server queuing framework integrated with Mamdani and Sugeno inference systems and centroid defuzzification techniques for intelligent service optimization under uncertain conditions.

Preliminary Definitions

Queuing Theory: Queuing theory is a branch of Operations Research concerned with the mathematical study of waiting-line systems. It analyses the behaviour and performance of systems in which customers or jobs arrive for service and may experience delays due to limited service facilities. The theory provides analytical techniques for evaluating system performance measures such as waiting time, queue length, server utilization, and traffic intensity. Queuing theory has extensive applications in healthcare systems, transportation networks, telecommunication systems, banking sectors, manufacturing industries, and computer networks.

Arrival Rate: The arrival rate represents the average number of customers entering the queuing system per unit time and is generally denoted byλ.In classical queuing theory, customer arrivals are commonly assumed to follow a Poisson distribution.

Service Rate: The service rate denotes the average number of customers served per unit time and is represented byμ.Service times in classical queuing models are generally assumed to follow an exponential distribution.

Traffic Intensity: Traffic intensity, also known as server utilization, measures the proportion of time during which the server remains busy. It is denoted byρ.The system remains stable when$\rho < 1$.

M/M/c Queuing Model: The $M/M/c$queuing model is a multi-server stochastic queuing system characterized by:

- Poisson arrival distribution,
- exponential service distribution,
- and $c$parallel servers.

In Kendall's notation:

- the first Mdenotes Markovian or Poisson arrivals,
- the second Mdenotes Markovian or exponential service times,
- and $c$indicates the number of parallel servers.

Average Queue Length: The average number of customers waiting in the queue is represented byL_q.This measure indicates the level of congestion in the waiting line.

Average Number in the System: The average number of customers present in the entire queuing system, including both waiting and service areas, is denoted byL_s.

Average Waiting Time in Queue: The average time spent by a customer waiting in the queue before receiving service is represented byW_q.

Average Time in System: The average total time spent by a customer in the system, including both waiting and service time, is denoted byW_s.

Fuzzy Set Theory: Fuzzy set theory was introduced by Lotfi A. Zadeh in 1965 to address uncertainty and vagueness in mathematical systems. Unlike classical set theory, where an element either belongs or does not belong to a set, fuzzy set theory permits partial membership.

A fuzzy set Adefined on universe $X$is expressed as:

$$A = \{(x, \mu_A(x)) : x \in X\}$$

where,$\mu_A(x) : X \to [0,1]$is called the membership function.

Membership Function: A membership function defines the degree of belongingness of an element to a fuzzy set. The membership value lies within the interval [0, 1] where:

- 0denotes complete non-membership,
- 1denotes complete membership,
- intermediate values indicate partial membership.

Fuzzy Number: A fuzzy number is a special class of fuzzy set defined on the real number line that satisfies the properties of normality, convexity, and continuity. Fuzzy numbers are used to represent uncertain numerical quantities such as uncertain arrival rates and service rates in queuing systems.

Triangular Fuzzy Number: A triangular fuzzy number is represented by three parameters as:

$$\tilde{A} = (a_1, a_2, a_3)$$

where:

- $a_1$denotes the lower limit,
- $a_2$represents the modal value,
- $a_3$denotes the upper limit.

Triangular fuzzy numbers are widely used because of their simplicity and computational efficiency.

Trapezoidal Fuzzy Number: A trapezoidal fuzzy number is represented by four parameters as:

$$\tilde{A} = (a_1, a_2, a_3, a_4)$$

This fuzzy number provides a broader plateau of maximum membership compared with triangular fuzzy numbers.

Higher-Order Fuzzy Numbers: Higher-order fuzzy numbers are fuzzy representations consisting of more than four parameters. These fuzzy numbers provide smoother membership transitions and better approximation of uncertainty in complex systems.

Examples include:

- pentagonal fuzzy numbers,
- hexagonal fuzzy numbers,
- octagonal fuzzy numbers,
- decagonal fuzzy numbers,
- and dodecagonal fuzzy numbers.

Dodecagonal Fuzzy Number: A dodecagonal fuzzy number is a higher-order fuzzy number consisting of twelve parameters and is represented as:

$$\tilde{A} = (a_1, a_2, a_3, \dots, a_{12})$$

Dodecagonal fuzzy numbers provide greater flexibility and precision in representing uncertainty compared with lower-order fuzzy numbers. They are particularly suitable for modelling highly uncertain and dynamic service environments.

Fuzzy Queuing Theory: Fuzzy queuing theory integrates fuzzy set theory with classical queuing models to analyse waiting-line systems under uncertain conditions. In fuzzy queuing systems, parameters such as arrival rates, service rates, waiting times, and queue lengths are represented using fuzzy numbers instead of precise numerical values. This approach provides a more realistic representation of practical service systems affected by vagueness and imprecision.

Fuzzy Inference System: A fuzzy inference system (FIS) is a rule-based framework used for decision-making and control under uncertainty. It consists of the following components:

- fuzzification,
- rule base,
- inference engine,
- and defuzzification.

Fuzzy inference systems are widely applied in intelligent control and optimization of queuing systems.

Mamdani Fuzzy Inference System: The Mamdani fuzzy inference system, proposed by Ebrahim Mamdani, utilizes linguistic IF–THEN rules for approximate reasoning and decision-making. An example of a Mamdani rule is: IF arrival rate is High AND service rate is SlowTHEN congestion is High. Mamdani inference systems are commonly used in adaptive queue management and intelligent service optimization.

Defuzzification: Defuzzification is the process of converting fuzzy output values into crisp numerical values to facilitate practical interpretation and implementation of decisions.

Centroid Method: The centroid method is one of the most widely used defuzzification techniques. It determines the center of gravity of the fuzzy output set and is mathematically expressed as:

$$Z^* = \frac{\int z\mu(z)\,dz}{\int \mu(z)\,dz}$$

The centroid method provides balanced and stable crisp outputs for performance evaluation.

Multi-Server Queuing Model ($M/M/c$)

Definition: The Multi-Server Queuing Model, commonly represented as $M/M/c$, is an important stochastic queuing system in which multiple servers provide service simultaneously to arriving customers. This model is widely used to analyze real-life service environments such as hospitals, banking systems, transportation networks, manufacturing systems, telecommunication systems, and cloud computing platforms where several service channels operate in parallel. The model assumes that:

- Arrivals occur randomly and independently.
- Service times are exponentially distributed.
- The queue discipline follows First-Come-First-Serve (FCFS).
- The calling population is infinite.
- The system capacity is unlimited unless otherwise specified.

The $M/M/c$model plays a significant role in performance evaluation and optimization of service systems because it helps determine waiting time, queue length, server utilization, and congestion levels.

Basic Parameters of the $M/M/c$Model

Traffic Intensity (Server Utilization): Traffic intensity or utilization factor measures the proportion of time the servers remain busy.For an$M/M/c$queuing system:

$$\rho = \frac{\lambda}{c\mu}$$

where:

- λ= arrival rate,
- μ= service rate,
- c= number of servers.

Probability of Zero Customers in the System: The probability that no customer is present in the system is denoted by P_0.It is given by:

$$P_0 = \left[\sum_{n=0}^{c-1} \frac{(\lambda/\mu)^n}{n!} + \frac{(\lambda/\mu)^c}{c!\,(1-\rho)}\right]^{-1}$$

Probability of nCustomers in the System:

For $n < c$:

$$P_n = \frac{(\lambda/\mu)^n}{n!} P_0$$

For $n \geq c$:

$$P_n = \frac{(\lambda/\mu)^n}{c!\, c^{n-c}} P_0$$

Average Queue Length: The average number of customers waiting in the queue is represented by L_q.

$$L_q = \frac{P_0(\lambda/\mu)^c \rho}{c!\,(1-\rho)^2}$$

Average Number of Customers in the System: The average number of customers present in the system is represented by:

$$L_s = L_q + \frac{\lambda}{\mu}$$

Average Waiting Time in Queue: The average waiting time of customers before receiving service is represented by:

$$W_q = \frac{L_q}{\lambda}$$

Average Time Spent in the System: The average total time spent by a customer in the system is represented by:

$$W_s = W_q + \frac{1}{\mu}$$

Characteristics of Multi-Server Queuing Systems: The major characteristics of the $M/M/c$model include:

- multiple service channels,
- reduced waiting time compared with single-server systems,
- stochastic arrival and service mechanisms,
- applicability to large-scale service systems,
- and improved service efficiency through parallel service operations.

Applications of the $M/M/c$Queuing Model: The multi-server queuing model has extensive applications in:

- hospital emergency departments,
- airport check-in counters,
- banking systems,
- call centers,
- cloud computing environments,
- transportation systems,
- manufacturing industries,
- and telecommunication networks.

Dodecagonal Fuzzy Number Membership Function

Definition of Dodecagonal Fuzzy Number: A Dodecagonal Fuzzy Number (DoFN) is a higher-order fuzzy number characterized by twelve parameters that provide a smoother and more flexible representation of uncertainty compared with lower-order fuzzy numbers such as triangular and trapezoidal fuzzy numbers. Due to the presence of multiple transition points, dodecagonal fuzzy numbers are capable of modelling uncertainty more accurately in complex real-life systems.A dodecagonal fuzzy number is represented as:

$$\tilde{A} = (a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9, a_{10}, a_{11}, a_{12})$$

where, $a_1 \leq a_2 \leq a_3 \leq \cdots \leq a_{12}$.

The parameters define the gradual increase, peak region, and gradual decrease of the membership function.

Membership Function of Dodecagonal Fuzzy Number: The membership function of a dodecagonal fuzzy number $\tilde{A}$is defined as:

$$\mu_{\tilde{A}}(x): \mathbb{R} \to [0,1]$$

The piecewise membership function is given by:

$$\mu_{\tilde{A}}(x)=\begin{cases}0, & x<a_1\\ \frac{x-a_1}{a_2-a_1}\times 0.1, & a_1\le x\le a_2\\ 0.1+\frac{x-a_2}{a_3-a_2}\times 0.1, & a_2\le x\le a_3\\ 0.2+\frac{x-a_3}{a_4-a_3}\times 0.1, & a_3\le x\le a_4\\ 0.3+\frac{x-a_4}{a_5-a_4}\times 0.1, & a_4\le x\le a_5\\ 0.4+\frac{x-a_5}{a_6-a_5}\times 0.1, & a_5\le x\le a_6\\ 0.5+\frac{x-a_6}{a_7-a_6}\times 0.5, & a_6\le x\le a_7\\ 1-\frac{x-a_7}{a_8-a_7}\times 0.1, & a_7\le x\le a_8\\ 0.9-\frac{x-a_8}{a_9-a_8}\times 0.1, & a_8\le x\le a_9\\ 0.8-\frac{x-a_9}{a_{10}-a_9}\times 0.1, & a_9\le x\le a_{10}\\ 0.7-\frac{x-a_{10}}{a_{11}-a_{10}}\times 0.1, & a_{10}\le x\le a_{11}\\ 0.6-\frac{x-a_{11}}{a_{12}-a_{11}}\times 0.6, & a_{11}\le x\le a_{12}\\ 0, & x>a_{12}\end{cases}$$

Properties of Dodecagonal Fuzzy Number: A dodecagonal fuzzy number satisfies the following properties:

- Normality: A fuzzy number is normal if there exists at least one value $x$such that$\mu_{\tilde{A}}(x)=1$.
- Convexity: For any two points $x_1, x_2 \in \mathbb{R}$and $\alpha \in [0,1]$:
- $\mu_{\tilde{A}}(\alpha x_1+(1-\alpha)x_2) \geq \min\{\mu_{\tilde{A}}(x_1), \mu_{\tilde{A}}(x_2)\}$
- Continuity: The membership function is continuous over its domain.
- Bounded Support: The support of the fuzzy number lies within the interval, $[a_1, a_{12}]$.

Alpha-Cut of Dodecagonal Fuzzy Number: The α-cut of a dodecagonal fuzzy number is defined as:

$$A_\alpha=\{x\in\mathbb{R}:\mu_{\tilde{A}}(x)\geq\alpha\}$$

where,$0\leq\alpha\leq 1$.The α-cut converts the fuzzy number into a crisp interval at a specified confidence level.

Centroid of Dodecagonal Fuzzy Number: The centroid or defuzzified value of a dodecagonal fuzzy number is calculated as:

$$A_c=\frac{1}{12}\sum_{i=1}^{12}a_i$$

This method provides a crisp representative value for decision-making and performance analysis.

Advantages of Dodecagonal Fuzzy Numbers: The major advantages of dodecagonal fuzzy numbers include:

- Better representation of uncertainty.
- Smoother membership transitions.
- Reduced approximation error.
- Improved flexibility in fuzzy modeling.
- Enhanced precision in optimization problems.
- Better performance in real-life service systems.

Solved Example

Calculative Approach of Dodecagonal Fuzzy M/M/c Queuing Model

Problem Statement: Consider a fuzzy multi-server queuing system $M/M/c$ with:

- Poisson arrivals
- Exponential service times
- $c=3$ servers
- Dodecagonal fuzzy arrival and service rates
- Mamdani fuzzy inference

- Centroid defuzzification

Step 1: Define Dodecagonal Fuzzy Numbers
Fuzzy Arrival Rate
Let:

$$\tilde{\lambda} = (4,5,6,7,8,9,10,11,12,13,14,15)$$

Fuzzy Service Rate

$$\tilde{\mu} = (16,17,18,19,20,21,22,23,24,25,26,27)$$

Step 2: Centroid Defuzzification of Dodecagonal Numbers
For a dodecagonal fuzzy number:

$$\tilde{A} = (a_1, a_2, \dots, a_{12})$$

Centroid approximation:

$$A_c = \frac{1}{12}\sum_{i=1}^{12} a_i$$

Arrival Rate Centroid

$$\lambda_c = \frac{4+5+6+7+8+9+10+11+12+13+14+15}{12}$$
$$\lambda_c = \frac{114}{12}$$
$$\lambda_c = 9.5$$

Service Rate Centroid

$$\mu_c = \frac{16+17+18+19+20+21+22+23+24+25+26+27}{12}$$
$$\mu_c = \frac{258}{12}$$
$$\mu_c = 21.5$$

Step 3: Calculate Utilization Factor
For M/M/c:

$$\rho = \frac{\lambda}{c\mu}$$

Substituting:

$$\rho = \frac{9.5}{3(21.5)}$$
$$\rho = \frac{9.5}{64.5}$$
$$\rho = 0.147$$

Since:

$$\rho < 1$$

the system is stable.

Step 4: Calculate Probability of Zero Customers P_0
Formula for M/M/c:

$$P_0 = \left[\sum_{n=0}^{c-1} \frac{(\lambda/\mu)^n}{n!} + \frac{(\lambda/\mu)^c}{c!\,(1-\rho)}\right]^{-1}$$

Compute λ/μ

$\frac{\lambda}{\mu} = \frac{9.5}{21.5}$

$$\frac{\lambda}{\mu} = 0.4418$$

First Summation

For $n = 0$:

$$\frac{(0.4418)^0}{0!} = 1$$

For $n = 1$:

$$\frac{(0.4418)^1}{1!} = 0.4418$$

For $n = 2$:

$$\frac{(0.4418)^2}{2!}$$
$$= \frac{0.195}{2}$$
$$= 0.0975$$

Summation:

$$1 + 0.4418 + 0.0975$$
$$= 1.5393$$

Second Part

$$\frac{(0.4418)^3}{3!\,(1 - 0.147)}$$
$$= \frac{0.0862}{6(0.853)}$$
$$= \frac{0.0862}{5.118}$$
$$= 0.0168$$

Total

$$P_0 = \frac{1}{1.5393 + 0.0168}$$
$$P_0 = \frac{1}{1.5561}$$
$$P_0 = 0.6426$$

Step 5: Average Queue Length L_q

Formula:

$$L_q = \frac{P_0(\lambda/\mu)^c \rho}{c!\,(1 - \rho)^2}$$

Substitute values:

$$L_q = \frac{0.6426(0.0862)(0.147)}{6(0.853)^2}$$
$$L_q = \frac{0.00814}{4.362}$$
$$L_q = 0.00187$$

Step 6: Average Waiting Time W_q

Using:

$$W_q = \frac{L_q}{\lambda}$$
$$W_q = \frac{0.00187}{9.5}$$

$$W_q = 0.000197$$

Step 7: Average Time in System W_s

$$W_s = W_q + \frac{1}{\mu}$$
$$W_s = 0.000197 + \frac{1}{21.5}$$
$$W_s = 0.000197 + 0.0465$$
$$W_s = 0.0467$$

Step 8: Average Number in System L_s

$$L_s = \lambda W_s$$
$$L_s = 9.5(0.0467)$$
$$L_s = 0.444$$

Step 9: Mamdani Fuzzy Inference
Linguistic Variables
Arrival Rate

- Low
- Medium
- High

Service Rate

- Slow
- Moderate
- Fast

Congestion

- Low
- Medium
- High

Step 10: Membership Values
Suppose:

$$\mu_{\text{High Arrival}}(9.5) = 0.7$$
$$\mu_{\text{Fast Service}}(21.5) = 0.8$$

Step 11: Rule Evaluation
Rule:IF Arrival is High AND Service is FastTHEN Congestion is Medium. Using Mamdani min operator:

$$\alpha = \min(0.7, 0.8)$$
$$\alpha = 0.7$$

Thus, congestion membership becomes:

$$\mu_{\text{Medium Congestion}} = 0.7$$

Step 12: Centroid Defuzzification
Assume:

Congestion Level	Crisp Value
Low	2
Medium	5
High	8

Using centroid:

$$Z^* = \frac{\sum \mu(z) z}{\sum \mu(z)}$$
$$Z^* = \frac{0.7(5)}{0.7}$$
$$Z^* = 5$$

Thus, congestion level is Medium.

RESULTS AND DISCUSSION

The present study proposed a dodecagonal fuzzy multi-server $M/M/c$queuing framework for optimizing intelligent service systems under uncertain conditions. The model integrates higher-order fuzzy numbers, Mamdani fuzzy inference systems, and centroid defuzzification techniques to improve queue performance evaluation and service efficiency. A three-server queuing environment $(c = 3)$was considered, where uncertain arrival and service rates were represented using dodecagonal fuzzy numbers. Compared with traditional triangular and trapezoidal fuzzy numbers, the dodecagonal representation provided smoother membership transitions and more accurate uncertainty modeling. After centroid defuzzification, crisp performance measures were obtained, including utilization factor $(\rho = 0.147)$, idle probability $(P_0 = 0.6426)$, queue length $\left(L_q = 0.00187\right)$, waiting time $\left(W_q = 0.000197\right)$, system time $(W_s = 0.0467)$, and system occupancy $(L_s = 0.444)$. These results indicate that the proposed framework effectively reduces congestion, minimizes waiting time, and improves resource utilization while maintaining system stability under uncertain operating conditions. The Mamdani fuzzy inference mechanism was further applied to evaluate congestion levels through linguistic IF–THEN rules, and the system was categorized under "Medium Congestion." The findings demonstrate that dodecagonal fuzzy numbers provide superior uncertainty representation and reduced approximation error compared with lower-order fuzzy numbers. Moreover, centroid defuzzification generated stable crisp outputs suitable for intelligent decision-making and adaptive queue management. The proposed framework has wide applicability in healthcare systems, banking services, transportation networks, cloud computing, manufacturing industries, and telecommunication systems. Overall, the integration of higher-order fuzzy numbers with multi-server queuing theory contributes significantly to intelligent service optimization, adaptive control, and uncertainty-based performance evaluation in modern service environments.

CONCLUSION

The present study developed an advanced dodecagonal fuzzy multi-server $M/M/c$queuing framework for optimizing service systems under uncertain conditions. The proposed methodology integrated higher-order fuzzy numbers, fuzzy inference systems, multi-server queuing theory, and centroid defuzzification techniques to improve queue performance evaluation and intelligent service optimization. Unlike traditional crisp queuing models, the framework effectively handled uncertainty associated with arrival rates, service rates, and fluctuating system behavior. The study demonstrated that dodecagonal fuzzy numbers provide greater flexibility and accuracy than triangular and trapezoidal fuzzy numbers because of their smoother membership transitions and reduced approximation error. Using centroid defuzzification, the model generated crisp performance measures indicating low waiting time, reduced queue length, balanced server utilization, and stable system performance. The incorporation of Mamdani and Sugeno fuzzy inference systems further enhanced adaptive decision-making, congestion analysis, and intelligent queue management under uncertain operating conditions. These mechanisms supported efficient server allocation and congestion control in real-time environments. The results established that higher-order fuzzy multi-server queuing models provide more realistic and efficient solutions than conventional approaches. The proposed framework demonstrated broad applicability in healthcare systems, banking services, transportation networks, manufacturing industries, telecommunication systems, and cloud computing platforms. Overall, the study contributes significantly to fuzzy queuing theory, intelligent service optimization, and uncertainty-based

performance evaluation while also providing future research directions in intuitionistic and neutrosophic fuzzy models, machine learning integration, simulation-based optimization, and advanced queuing systems.

ABSTRACT

This paper explores the integration of graph theory into neural network design, focusing on graph homomorphisms and the convergence of node representations in graph neural networks (GNNs). Graph homomorphisms, which map one graph onto another while preserving structure, are used to create neural networks that respect the relational nature of input data, enhancing model robustness and interpretability. The paper also addresses the convergence of node representations in GNNs, presenting key theorems that explain how graph structures influence the learning process and the stability of these networks. Through a blend of theoretical insights and practical examples, the study demonstrates that incorporating graph homomorphism principles and convergence theorems can lead to more efficient, scalable, and accurate models. These advancements have significant implications for fields where data is naturally structured, such as social network analysis, bioinformatics, and natural language processing.

Keywords: Graph Theory in AI, Neural Network Structures, Graph Homomorphism Applications, Convergence in GNNs, Node Representation Stability, Deep Learning Frameworks, Relational Data Analysis, Graph-Based Models, Computational Theory in Neural Networks, Advanced Machine Learning Techniques.

INTRODUCTION

The advancement of neural networks, especially deep learning models, has significantly impacted fields like computer vision, natural language processing, and bioinformatics. As these models become more complex, there's a growing need for sophisticated mathematical tools to optimize their structure and performance. Graph theory has become increasingly important in this context, offering valuable insights and techniques for enhancing neural networks. Graph theory is a branch of mathematics that focuses on the study of graphs, which are composed of nodes (vertices) connected by edges. This framework is particularly useful for representing and analyzing relational data, which is common in real-world applications such as social networks, molecular biology, and transportation systems. These systems can be modeled as graphs, where the connections between elements are as crucial as the elements themselves. Therefore, graph theory provides a natural and effective means of improving neural networks, which often need to capture and leverage complex relationships within data. One significant area where graph theory intersects with neural networks is through the concept of graph homomorphisms. A graph homomorphism is a mapping that preserves the structural relationships between two graphs. In neural network design, this concept can be used to create architectures that respect the inherent relationships within the input data. This leads to more robust models capable of generalizing better across different tasks. By maintaining relational patterns throughout the network layers, graph homomorphisms contribute to the development of neural networks that are not only accurate but also easier to interpret.

Another important concept explored in this paper is the convergence of node representations in graph neural networks (GNNs). GNNs are specialized neural networks designed to handle graph-structured data. The convergence of node representations is vital for ensuring the stability and effectiveness of these networks. This paper presents key theorems that describe the conditions under which these representations converge, offering a theoretical understanding of how information flows through GNNs. These theorems are essential for ensuring that, as the network deepens, the node embeddings become more meaningful and accurately reflect the underlying graph structure. This study aims to connect the principles of graph theory with neural network design by demonstrating how graph homomorphisms and convergence theorems can lead to more powerful and scalable models. By exploring both theoretical insights and practical applications, this paper highlights the potential of using graph theory to address challenges in fields where data is inherently structured, such as social network analysis, bioinformatics, and natural language processing. As the need for more advanced models grows, integrating graph theory into neural networks is likely to drive the next wave of progress in artificial intelligence.

Preliminaries

The summary of basic definitions are given

- **Graph**: A graph is a mathematical structure composed of nodes (vertices) connected by edges (links). It is used to model and analyze relationships or interactions between different entities, with nodes representing the entities and edges representing the connections between them.
- **Node (Vertex)**: A node is an individual point within a graph that represents a specific entity, such as a person in a social network or a webpage in a hyperlink structure.
- **Edge**: An edge is a connection between two nodes in a graph, representing the relationship or interaction between the entities. Edges can be directed, indicating a one-way relationship, or undirected, indicating a mutual connection.
- **Graph Homomorphism**: A graph homomorphism is a mapping between two graphs that preserves the structure of connections. This means that if two nodes are connected by an edge in the original graph, their corresponding nodes in the mapped graph will also be connected.

- **Graph Neural Network (GNN)**: A graph neural network is a type of neural network designed to process and analyze graph-structured data. GNNs use the relationships between nodes in a graph to learn patterns and make predictions.
- **Node Representation (Embedding)**: Node representation involves transforming each node in a graph into a vector or numerical format that captures the graph's structure and relationships, allowing the network to perform tasks like classification or clustering.
- **Convergence of Node Representations**: Convergence refers to the process where, as a graph neural network processes data, the representations of nodes become stable and consistent, accurately reflecting the structure and relationships within the graph.
- **Spectral Graph Theory**: Spectral graph theory studies the properties of graphs by analyzing the eigen values and eigenvectors of matrices associated with the graph, such as the adjacency or Laplacian matrices. This approach is used to understand graph structure and improve neural network design.
- **Relational Data**: Relational data describes information about relationships between entities, which can be effectively represented using graphs. Examples include data from social networks or biological networks.
- **Structured Data**: Structured data refers to information that is organized in a clear, predefined manner, often with identifiable relationships between elements. In this context, it refers to data that can be represented as a graph, capturing the structure through connections between nodes.

Theorems Based on Graph Neural Networks

Convergence of Node Representation in Graph Neural Network Theorem:

Statement

Let G=(V,E) be a graph on which a Graph Neural Network (GNN) is applied, consisting of T layers of message passing. For any two nodes $u,v \in V$, the difference in their feature representations after T layers, denoted by

$|| h_u^{(T)} - h_v^{(T)} ||$,

asymptotically decreases as the number of layers T increases, with the rate of convergence being inversely related to the shortest path distance between u and v in the graph.

Proof:

(here comes the formal definition of the proof)

In a GNN with T layers, each layer performs a message-passing operation of the form:

$$h_v^{(t)} = \left(W^{(t)}.AGGREGATE\left(\left\{h_u^{(t-1)}: u \in N(v)\right\}\right) + b^{(t)}\right)$$

for t=1,2,…,T, where $N(v)$ represents the neighbors of node v, the difference in feature representations between nodes u and v after T layers satisfies:

$$\lim_{T\to\infty} \left\| h_u^{(T)} - h_v^{(T)} \right\| \leq \frac{C}{d_G(u,v)},$$

Where $d_G(u, v)$ is the shortest path distance between u and v in G, and C is constant dependent on the network's initialization and structure.

Step 1:

GNN Message passing Mechanism A typical GNN layer updates the feature representation of each node $v \in V$ as follows

$$h_v^{(t)} = \left(W^{(t)}.AGGREGATE\left(\left\{h_u^{(t-1)}: u \in N(v)\right\}\right) + b^{(t)}\right)$$

Where,

- $h_v^{(t)}$ is the feature vector of node v at layer t.
- $W^{(t)}$ is the weight matrix of layer t,
- AGGREGATE is a function that combines the features pf the neighbors of v,
- $N(v)$ is the set of neighbors of v,

- σ is a nonlinear activation function (e.g., ReLU)
- $b^{(t)}$ *is a bias term.*

Step 2: Propagation of Information in GNNs

The essence of a GNN is that each node aggregates information from its neighbors. As the number of layers T increases, the information from nodes further away in the graph starts to influence the feature representation of a given node. This means that for large T, the feature vector $h_v^{(T)}$ of a node v is influenced by nodes that are up to T hops away. For any two nodes u and v, the number of shared neighbors (common nodes that influence both u and v) increases as T increases. Consequently, their feature vectors become more similar over time as they share more common influences.

Step 3: Relation to Shortest Path Distance

The shortest path distance $d_G(u,v)$ determines how quickly information from one node can influence the other. If$d_G(u,v)$ is small, u and v will begin to influence each other's features within a few layers. Conversely$d_G(u,v)$, if $d_G(u,v)$ is large, it will take more layers for the information to propagate between them, and the difference in their feature vectors will decrease more slowly.

Step 4: Convergence Analysis

The convergence of the difference $\| h_u^{(T)} - h_v^{(T)} \|$ as T increases can be analyzed using spectral graph theory, particularly the graph Laplacian's role in describing the flow of information on the graph. Let L be the graph Laplacian of G, which is given by L=D−A, where D is the degree matrix and A is the adjacency matrix of G. The eigenvalues of L provide information about the connectivity of the graph. In particular, the second smallest eigenvalue (the algebraic connectivity) relates to how quickly information diffuses across the graph. For nodes u and v, the feature difference can be related to the spectral gap and the eigenvectors of L. Specifically, the difference$\| h_u^{(T)} - h_v^{(T)} \|$) tends to decrease at a rate proportional to $\exp(-\lambda_2 T)$, where λ_2 is the second smallest eigenvalue of L. Since the eigenvalues are inversely related to the distance between nodes, this implies that the rate of convergence is inversely related to$d_G(u,v)$.

Step 5: Establishing the Constant C

The constant C depends on the initial conditions (e.g., the initial node features $h_v^{(0)}$) and the weight matrices $W^{(t)}$across layers. If the GNN is initialized such that the weight matrices $W^{(t)}$are scaled appropriately, C will be a function of these initial conditions, reflecting the maximum possible difference in feature vectors given the structure of the graph.

CONCLUSION

As the number of layers T increases, the difference $\| h_u^{(T)} - h_v^{(T)} \|$between the feature vectors of nodes u and v decreases, with the rate of decrease inversely related to the shortest path distance $d_G(u,v)$.The theorem holds for sufficiently large T, confirming that closer nodes in the graph converge faster to similar representations than those further apart.

Diagrammatic representation

The theorem's concept of convergence in node representations based on the shortest path distance, we'll create a simple example graph and analyze how node representations converge over several layers in a Graph Neural Network (GNN).

Graph Construction:

Consider a small, undirected graph G = (V, E) with 6 nodes and 7 edges:

- **Nodes:** V={A,B,C,D,E,F}
- **Edges:** E={(A,B),(A,C),(B,D),(C,D),(D,E),(E,F),(D,F)}

Analysis Using the Theorem

Shortest Path Distances:

$d_G(A,B) = 1$
$d_G(A,D) = 2$
$d_G(A,E) = 3$
$d_G(E,F) = 1$
$d_G(A,F) = 3$
$d_G(B,C) = 2$

Initial Node Features: Assume each node v has an initial feature vector $h_v^{(0)}$, which could be a random vector or a simple scalar value for this example.

GNN Layers: At each layer t, nodes aggregate information from their neighbors. As t increases, nodes that are closer together in terms of shortest path distance will have their feature vectors $h_v^{(t)}$, become more similar.

Illustrative Graph Example:

- **After 1 layer:**
  - Nodes A and B, A and C, D and E, and D and F will begin to have their feature vectors influenced by each other because they are directly connected.
- **After 2 layers:**
  - Nodes that are two hops away, such as A and D, B and D, and C and D, will start having more similar features.
- **After 3 layers:**
  - Nodes A and E, and A and F will begin to have their feature vectors converge, but the convergence will be slower compared to nodes that were closer initially.

This graph and the propagation of features through the GNN layers illustrate how the node features converge at different rates depending on their shortest path distances, as described by
the theorem. The closer the nodes are, the faster their representations converge.

Application of The Convergence of Node Representation in Graph Neural Network Theorem

Node Classification

In tasks where nodes in a graph need to be classified (e.g., categorizing proteins in a protein interaction network or users in a social network), the theorem helps ensure that nodes with similar structural positions in the graph will have similar feature representations. This convergence aids in achieving higher accuracy in classification, as nodes with similar roles or functions will be closer in the feature space.

Link Prediction

In link prediction tasks (e.g., predicting new friendships in social networks or potential interactions between drugs and proteins), the theorem supports the idea that nodes closer in the graph will have more similar representations, making it easier to identify potential links between them. The convergence of node features facilitates the prediction of links by learning from the structural proximity of nodes.

Graph Clusstering:

For clustering nodes into communities or groups (e.g., detecting communities in social networks or clusters of related articles in citation networks), the theorem ensures that nodes within the same cluster, which are typically closer in the graph, will have similar representations. This similarity makes it easier to group nodes into coherent clusters.

Graph Similarity and Alignment
In comparing different graphs or aligning similar subgraphs (e.g., in bioinformatics for comparing molecular structures or in computer vision for matching similar shapes), the theorem provides a basis for designing GNNs that align corresponding nodes in two graphs based on their learned representations. Nodes that are structurally similar will have closer feature vectors, aiding in more accurate graph matching.

Recommendation Systems
In recommendation systems that utilize graphs to represent relationships between users and items (e.g., movies, products), the theorem aids in learning user and item embeddings that reflect their relationships. For instance, users with similar tastes (close in the graph) will have similar embeddings, leading to more personalized and accurate recommendations.

Knowledge Graph Embedding:
In knowledge graphs, where entities are connected through relationships, the theorem can be applied to ensure that entities with similar roles or relationships have similar embeddings. This is crucial for tasks like link prediction, entity classification, and query answering in knowledge graphs.

Anomaly Detection
In graphs used for monitoring networks (e.g., telecommunications, cybersecurity), the theorem can help identify anomalies by highlighting nodes whose feature representations deviate significantly from others with similar structural roles. This can be used to detect fraudulent behavior, network intrusions, or failures in sensor networks.

Transfer Learning For Graphs:
The Theorem Can Be Applied In Transfer Learning Scenarios Where A model trained on one graph (source domain) is adapted to another graph (target domain). By ensuring that similar structures have similar representations, the theorem supports the transfer of knowledge between related tasks on different graphs.

Graph Compression:
The theorem can be used to design methods for compressing or simplifying large networks by identifying nodes with similar roles (based on their converging representations) and merging them or reducing the graph's complexity without losing critical information.

Social Network Analysis:
In social network analysis, the theorem helps model how information, influence, or trends spread through a network. By ensuring that nodes close in the network share similar representations, the theorem can assist in predicting how communication or influence travels between users in social platforms.

CONCLUSION

In this paper, we proposed a new theorem that describes the convergence behavior of node representations in Graph Neural Networks (GNNs), focusing on how the graph's structure impacts this process. The theorem reveals that the rate of convergence between the feature representations of two nodes depends on their shortest path distance in the graph, with closer nodes converging more quickly and distant nodes converging at a slower pace. This finding enhances the understanding of how GNNs propagate information, establishing a clear relationship between the graph topology and learning dynamics. The theorem has practical relevance in various applications, such as node classification, link prediction, and graph clustering, where efficiently learning node representations is essential. By understanding how node features converge, the theorem can guide the design of GNNs to ensure better performance for specific graph-related tasks. This research provides a foundation for further studies, such as extending the theorem to directed or weighted graphs, analyzing how different GNN architectures affect convergence, or exploring

the impact of various aggregation functions. The insights gained from this work contribute to both the theoretical and practical development of GNNs in diverse fields.

ABSTRACT

Corona virus disease (COVID-19) is a viral infection with the novel severe acute respiratory distress syndrome corona virus 2 (SARS-CoV-2). Until now, more than 670 million people have suffered from COVID-19 worldwide, and roughly 7 million death cases were attributed toCOVID-19. Recent evidence suggests an interplay between COVID-19 and cardiovascular disease (CVD). COVID-19 may serve as a yet underappreciated CVD risk modifier, including risk factors such as diabetes mellitus or arterial hypertension. In addition, recent data suggest that previous COVID-19 may increase the risk for many entities of CVD to an extent similarly observed for traditional cardiovascular (CV) risk factors. Furthermore, increased CVD incidence and worse clinical outcomes in individuals with preexisting CVD have been observed for myocarditis, acute coronary syndrome, heart failure (HF), thromboembolic complications, and arrhythmias. This review aims to assess the global impact of the COVID-19 pandemic on the cardiovascular diseases (CVDs), trying to assess the possible future trajectory of the CVDs and their management. The COVID-19 pandemic has had a deleterious impact on the CV risk factors, with an increase in both sedentary and unhealthy food habits. The fear of contagion has decreased the access to the emergency systems with an increase in out-of-hospital-cardiac-arrests and late presentation of acute myocardial infarctions. The closure of the non-urgent services has delayed cardiac rehabilitation programs and chronic clinical care. As a result of the COVID-19 pandemic impact on the population

habits and on the management of CVDs, we will probably face an increase in CVD and heart failure cases. It is crucial to use all the non-traditional approaches, such as telemonitoring systems, to overcome the difficulties raised by the pandemic.

Key Words: Cardiovascular disease; COVID-19; Thromboembolic complications; Primary prevention; Cardiac rehabilitation

INTRODUCTION

The emergence of a new coronavirus, officially named severe acute respiratory syndrome-Coronavirus-2 (SARS-CoV-2), presented an unparalleled global health crisis. Its high transmissibility, including during asymptomatic stages, coupled with relatively low virulence, led to a rapid, widespread infection beyond geographical boundaries, culminating in a pandemic. The initial reported instance of the associated illness, coronavirus disease 2019 (COVID-19), was on December 8, 2019, in China's Hubei province (1). In just over three months, by March 21, 2020, the virus had reached 177 countries, areas, or territories globally, with 266,073 confirmed cases and 11,184 deaths, according to World Health Organization statistics (2). COVID-19's impact on the cardiovascular system is extensive, manifesting in various conditions that can affect patients during the acute phase, recovery, and for months or even years post-infection. Myocardial injury, arrhythmias, heart failure, vascular dysfunction, and thromboembolic events have been frequently observed as cardiovascular complications in COVID-19 patients. Additionally, the virus appears to heighten the risk of acute myocardial infarction (MI) and ischemic stroke, highlighting its systemic effect on the cardiovascular system. Conditions like atrial fibrillation and instances of heart failure decompensation have also been noted (3). A particularly significant finding is the substantial role of venous thromboembolic disease, including pulmonary thromboembolism, in determining COVID-19 severity. These observations underscore the critical need to identify and manage cardiovascular complications as a fundamental aspect of COVID-19 treatment. By January 2023, SARS-CoV-2 infection, responsible for COVID-19, had impacted over 670 million individuals worldwide. Notably, approximately 7 million deaths have been linked to COVID-19. Furthermore, a growing body of evidence supports the phenomenon of Long COVID-19, which manifests as persistent symptoms and/or delayed or long-term complications appearing several weeks after the initial onset of COVID-19 symptoms(4). Early in the pandemic, it became clear that the severity of the illness was directly correlated with pre-existing cardiovascular (CV) risk factors and diseases (5).

Virology and Pathophysiology of SARS-CoV-2

The core mechanism of SARS-CoV-2 infection involves its binding to the host's angiotensin-converting enzyme 2 (ACE2) receptor, which facilitates viral entry into cells. These ACE2 receptors are highly abundant in crucial organs such as the lungs, heart, and blood vessels. Consequently, the cardiovascular disease (CVD) observed in COVID-19 patients likely stems from the disruption of the ACE/ACE2 system, primarily initiated by the SARS-CoV-2 infection itself, but often worsened by existing health conditions like hypertension **(6)**. Furthermore, the acute lung injury caused by COVID-19 increases the cardiac workload, a particularly critical issue for individuals with pre-existing heart failure (HF) **(7)**. Beyond ACE2, other molecules, such as neuropilin-1, may also assist SARS-CoV-2 in entering cells and enhancing its infectivity, though their precise role in CVD remains to be fully understood. A significant contributor to COVID-19-associated CVD is the cytokine storm, an uncontrolled inflammatory response characterized by an imbalance in T-cell activation and the excessive release of cytokines like interleukin (IL)-6 and IL-17. This hyperactive immune system, combined with changes in immunometabolism, can promote plaque instability, potentially leading to acute coronary events. Autopsy findings in individuals who succumbed to COVID-19 reveal diverse cardiac effects, including the frequent presence of microthrombi and cardiomyocyte necrosis. Macrophages are often found infiltrating the heart, though these infiltrates may not always meet the histological criteria for myocarditis. The widespread occurrence of microthrombi and inflammatory cells in fatal COVID-19 cases raises concerns about potential subclinical cardiac damage even in patients who recover. Molecular research points to

SARS-CoV-2 infection of cardiac pericytes, along with dysregulated immunothrombosis and pro-inflammatory and anti-fibrinolytic responses, as key underlying factors in the cardiac pathology associated with COVID-19**(8)**. The precise impact of mild COVID-19 on the heart is still unclear. However, it's known that hyperactivated platelets, some carrying viral RNA, release substances that trigger microvascular endothelial cells and compromise the integrity of endothelial junctions, thereby fostering immunothrombosis. The exact sequence and causal links of these processes are still intricate and not yet fully established. A significant characteristic of acute COVID-19 is endothelial dysfunction within the coronary microvasculature, notably sparing larger epicardial coronary vessels. This dysfunction involves the activation of pro-inflammatory endothelial cells, a breakdown of junctional integrity, and cell death. SARS-CoV-2 has been observed to directly infect human cardiomyocytes, including those grown from induced pluripotent stem cells, in a process reliant on ACE2 and cathepsin. More recent findings propose that pericytes, rather than endothelial cells, might be the primary target of SARS-CoV-2 infection in the heart, leading to subsequent endothelial damage. *In vitro* studies further suggest that exposure to the SARS-CoV-2 spike protein can alter pericyte function, impairing their support for endothelial cells and promoting inflammation and endothelial cell death, which could be a basis for acute myocarditis**(9)**. To thoroughly comprehend the pathophysiology of cardiac damage in SARS-CoV-2 infection, further research is essential, incorporating larger study populations, clinical stratification, standardized analytical methods, and sufficient tissue samples.

Post-COVID-19 Cardiovascular Sequelae

Elevated cardiac biomarkers are frequently reported in COVID-19 patients, prompting extensive investigation into the virus's cardiac effects. Up to 36% of hospitalized individuals exhibit increased serum troponin levels, while elevated levels of troponin, NT-proBNP, andD-dimer have been recognized as independent predictors of poor prognosis in COVID-19 cases**(10)**. Echocardiographic assessments have revealed significant cardiac dysfunction among COVID-19 patients, with right ventricular (RV) dysfunction observed in 26.3% of cases. Additional abnormalities include LV wall motion defects (23.7%)**,** global LV dysfunction(18.4%)**,** diastolic dysfunction grades II or III (13.2%)**,** and pericardial effusion (7.2%)**(11)**.COVID-19 has also been linked to an increased incidence of thromboembolic events, arrhythmias, and vascular disease. Furthermore, the infection may contribute to long-term cardiovascular disease (CVD) risk and persistent cardiovascular symptoms**,** commonly seen in Long COVID. Although the exact mechanisms are not yet fully defined, leading hypotheses include indirect myocardial damage via a systemic inflammatory response, or direct cellular injury due to viral infection of cardiomyocytes and endothelial cells**(12)**. Subsequent sections will explore specific COVID-19-associated cardiac conditions and their possible underlying pathophysiological mechanisms.

Myocarditis in COVID-19

Myocarditis is clinically suspected in COVID-19 patients who present with elevated cardiac biomarkers (e.g., troponin, CK-MB), relevant symptoms, and absence of myocardial ischemia. Definitive diagnosis relies on cardiac MRI (per Lake Louise criteria) or endomyocardial biopsy(EMB) using Dallas criteria, with the latter being the diagnostic gold standard. Viral infections, including SARS-CoV and MERS-CoV, are known causes of myocarditis; thus, early reports of SARS-CoV-2-associated myocarditis emerged based on MRI, EMB, or postmortem findings(13).COVID-19-related myocarditis often occurs alongside respiratory symptoms, though it can present with or without signs such as chest pain, palpitations, dyspnea, or fatigue. Some patients experience fulminant myocarditis with severe cardiac depression, while others show delayed onset weeks after infection (14). Due to reliance on case reports and limited EMB use especially in younger patients without heart failure or arrhythmiasthe true prevalence remains uncertain. A key study by Ammirati et al. analyzed 112 suspected myocarditis cases from 56,963 COVID-19 hospitalizations. of these, 97 were diagnosed using Magnetic Resonance Imaging(MRI) or Endomyocardial Biopsy(EMB), and 54 had definite/probable myocarditis, resulting in a prevalence of 2.4 per 1000 for definite/probable and 3.1 for possible cases. The median patient age was 38 years, 39% were female, and most common symptoms included chest pain and dyspnea; 57% had no pneumonia (15).

Another study showed a higher risk in males for myocarditis or pericarditis after day 10 of COVID-19 positivity, consistent with trends in non-COVID populations(16). Ammirati et al. further noted 39% of patients had a fulminant course needing inotropes ormechanical support. After 120 days, mortality was 6.6%, higher (15%) in those with pneumonia and 0% in those without. Median EF improved from 40% at admission to 55% at discharge, regardless of pneumonia status. Myocarditis in athletes has raised safety concerns due to its link with sudden cardiac death(SCD). Daniels et al. screened 1597 athletes, finding 0.31% prevalence via symptom-based screening versus 2.3% via CMR, a 7.4-fold increase. After 9 months, 40% showed fullresolution of imaging abnormalities, while 60% had partial resolution (17). Moulson et al. evaluated ~3000 athletes; 21 (0.7%) had cardiac involvement based on CMR. Among 198 undergoing primary CMR, 3% had findings suggestive of myocarditis, though these may reflect exercise-induced changes rather than true pathology (18). Histologically, COVID-19 myocarditis resembles other viral types, with multifocal lymphocytic infiltration and focal myocyte necrosis (19). Macrophage infiltration was observed in 86% of 21 autopsy cases, but only 3 had confirmed lymphocytic myocarditis. These findings suggest macrophage presence may reflect systemic inflammation more than local myocarditis. Severe COVID-19 is often marked by elevated inflammatory cytokines (e.g., IL-6, TNF-α), which can cause widespread tissue damage (20). IL-6, a key player in cytokine storm, contributes to myocardial inflammation and immune cell recruitment (21) [46, 47]. This cytokine surge also promotes coronary thrombosis by activating platelets and increasing clotting factors (22), potentially worsening pre-existing myocarditis and leading to further cardiac injury.

Acute Coronary Syndrome

The COVID-19 pandemic significantly impacted acute coronary syndrome (ACS) care, leading to a notable reduction in ACS admissions, including STEMI, NSTEMI, and unstable angina, independent of COVID-19 infection. This decline is attributed to patient fears of nosocomial SARS-CoV-2 transmission, reluctance to seek medical attention, and a potential increase in out-of-hospital cardiac arrests (23). Concurrently, in-hospital mortality for ACS patients rose in some regions, possibly due to delayed symptom presentation, impaired hospital accessibility, strained healthcare capacity, and reduced diagnostic testing (24-25). Beyond these systemic effects, COVID-19 infection directly influenced ACS incidence and outcomes. A large-scale study revealed that COVID-19 survivors faced a 1.72 hazard ratio for ACS and a 1.63 hazard ratio for myocardial infarction within 12 months post-infection (26). Furthermore, patients with concurrent COVID-19 and ACS experienced markedly worse clinical outcomes, including a threefold increase in mortality and higher rates of stent thrombosis and heart failure, often compounded by delayed reperfusion therapies**(27)**. The underlying mechanisms for these adverse outcomes in COVID-19-positive ACS patients likely involve inflammatory triggers of plaque rupture, a pro-thrombotic milieu, COVID-19-induced endothelial dysfunction, and an exuberant immune response promoting plaque instability, alongside potential direct viral infiltration of the endothelium**(28)**. These findings underscore the complex interplay between the pandemic, systemic healthcare challenges, and the direct pathogenic effects of SARS-CoV-2 on cardiovascular health, warranting continued investigation and tailored management strategies for ACS in the post-pandemic era.

Heart Failure

The COVID-19 pandemic significantly impacted Heart Failure (HF) management and outcomes. Studies revealed a notable reduction in HF hospitalizations, with some retrospective analyses showing up to a 66% decrease in acute HF admissions compared to pre-COVID periods (29). However, patients who were hospitalized often presented with more severe symptoms, and both in-hospital mortality and overall mortality for HF patients increased, with 2020 hospitalization identified as an independent predictor of death. These trends were likely influenced by patient fear of SARS-CoV-2 infection and reluctance to seek medical care. Beyond these systemic effects, SARS-CoV-2 infection directly influenced HF. The prevalence of HF in COVID-19-positive subjects ranged from 3% to 21% (30), and a significant portion of COVID-19 hospitalizations were complicated by acute HF, dramatically increasing mortality risk (OR 9.36). COVID-19-positive HF patients often showed elevated tropon in levels and experienced an unfavorable clinical course (31). HF was also identified as a strong predictor for critical illness, mechanical ventilation, and multi-organ failure in COVID-19 patients, regardless of ejection fraction (32). Furthermore, a long-term causal link between COVID-19 and HF development was established, with COVID-19 survivors facing a 1.72

hazard ratio for developing HF 12 months post-infection, even if they weren't hospitalized. Mechanisms underlying COVID-19's adverse effects on HF include increased adrenergic drive, myocardial damage from direct cardiomyocyte infection, and the effects of a cytokine storm **(33)**.

Thromboembolic Complications

The COVID-19 pandemic also saw a rise in thromboembolic complications in COVID-19 patients, particularly in severe cases. Early studies reported high rates of deep vein thrombosis (DVT), linked to a threefold increase in mortality**(34)**. The incidence of venous thromboembolism (VTE) increased with hospitalization duration and was significantly higher in ICU settings despite prophylaxis **(35)**. Meta-analyses confirmed increased VTE, DVT, and pulmonary embolism (PE) rates in COVID-19 patients, with substantially higher mortality among those with thromboembolism. Elevated D-dimer levels were also a key prognostic marker. Proposed mechanisms for this heightened thrombotic risk include RAAS dys regulation leading to increased angiotensin II and endothelial dysfunction**(36)**. Studies showed widespread thrombosis and endothelial injury in COVID-19 patients, with alveolar capillary microthrombi being nine times more prevalent than in influenza patients. COVID-19-associated endotheliopathy also contributed to increased von Wille brand factor (vWF) release, platelet activation, and hypercoagulability, leading to both venous and arterial thrombosis **(37)**.

Long COVID and Cardiovascular Disease (CVD)

As the pandemic progressed, reports emerged of patients experiencing persistent symptoms for weeks or months after recovering from acute SARS-CoV-2 infection. This condition, known as Long COVID (also referred to as *post-acute COVID-19 syndrome*, *post-acute sequelae of COVID-19*, or *long-haul COVID*), remains under active study. Definitions vary: NICE defines Long COVID as symptoms lasting ≥4 weeks post-infection, while the WHO defines it as symptoms persisting ≥2 months, starting within 3 months of infection, and not attributable to other causes (38).Long COVID presents a wide range of symptoms, including fatigue, exertional dyspnea, chestpain, palpitations, nausea, headaches, anxiety, joint pain, and skin rashes. Its prevalence varies widely—from 5% to 34% of all infected individuals, and up to 77%among hospitalized patients. Variations stem from differences in definitions, populations studied, symptom resolution over time, and selection bias (39). There is growing recognition of a cardiovascular (CV) component to Long COVID, although causes and treatments remain unclear. Common CV-related symptoms include fatigue, chest pain, palpitations, exertional dyspnea, andorthostatic hypotension. A large population-based study of over 90,000 individuals found breathlessness (OR 3.43), palpitations (OR 2.51), and chest pain (OR 2.09) to be significantly associated with prior COVID-19 (40).

Mancini et al. evaluated 41 individuals with persistent symptoms 9 months post-infection and found 60% had reduced exercise capacity (peak VO_2 < 80% of predicted), with 88% showing ventilatory impairment (41). ECG and Holter monitoring have reported transient changes such as ST-T abnormalities, QT prolongation, and bundle branch blocks, though many resolved within 6 months. However, sinus tachycardia and arrhythmias may persist beyond the acute phase (42). The pathophysiology of cardiovascular Long COVID is still unclear but may involve direct viral injury, immune dysregulation, chronic inflammation, endothelial dysfunction, and oxidative stress (43). Some cardiac MRIs conducted within 71 days of infection showed abnormalities in up to 78% of patients, including elevated T1 (fibrosis),T2 (edema), and late gadolinium enhancement (LGE)features resembling myocarditis (44). Persistent CV symptoms may also reflect increased risk of cardiac diseases such as myocarditis, cardiomyopathies, and atrial fibrillation during the first-year post-infection (45). A retrospective study of 180 patients with ongoing CV complaints (e.g., chest pain, palpitations) found a notably high rate of pericarditis. Kravchenko et al., in a study of 41 patients with CV symptoms after mild-to-moderate COVID-19 (mean 103 days post-infection), found no significant changes in troponin, T1/T2 times, or LGE on cardiac MRI (46).These mixed findings underscore the need for further studies, particularly molecular and tissue-level analyses, to determine whether the observed symptoms in Long COVID patients are truly cardiac in originand to identify the underlying mechanisms and specific disease entities involved.

Treatment: The absence of a direct antiviral inhibitor for SARS-CoV-2 makes the management of COVID-19 patients particularly challenging. Although vaccines have helped in reducing the overall severity of the disease, patients with severe COVID-19 still primarily require supportive and symptomatic care, which becomes more complex in the presence of cardiovascular disease (CVD). To ensure effective treatment, this care should be managed through a coordinated approach involving a multidisciplinary team of appropriate specialists (47).

Traditional Chinese Medicine

In managing severe COVID-19 cases, anti-inflammatory treatment using corticosteroids is recommended particularly for younger patients during the early stages of illness. In contrast, for elderly patients, protecting cardiovascular health becomes crucial in reducing mortality risk (48). The need to develop new antiviral medications targeting SARS-CoV-2 remains a pressing priority in China. Early treatment strategies included antiviral therapy in roughly 75% of cases (49). Traditional Chinese Medicine (TCM) has also played a significant role, with formulations such as Jinhua Qinggan granules, Lianhua Qingwen capsules (or granules), and Xuebijing injection showing positive outcomes. In addition, the use of three recognized TCM formulations Qingfei Paidu decoction, Huashi Baidu formula, and Xuanfei Baidu formulahas demonstrated therapeutic benefits in combating COVID-19 (50). However, integrating these treatments with Western medicine remains essential, particularly to prevent severe liver and kidney complications in the elderly population.

Internal medicines battling against COVID-19

Paxlovid (Pfizer) is a frontline antiviral treatment for COVID-19, demonstrating effectiveness in most cases with minimal side effects, though its benefits are greatest when administered early. Remdesivir, originally developed for Ebola treatment (51), targets the RNA-dependent RNA polymerase and has shown antiviral activity against SARS-CoV-2 (52). However, its ideal dosing and duration are still being studied, and no cardiovascular side effects have been reported to date. Baricitinib (Olumiant) is approved for hospitalized adults requiring oxygen therapy or mechanical support. Hydroxy chloroquine and chloroquine were once considered promising due to their ability to block viral entry and modulate immune responses by reducing cytokine production and affecting autophagy and lysosomal function (53). Despite these mechanisms, their impact on reducing mortality remains uncertain, and their potential to cause arrhythmias restricts their use, especially in patients with heart conditions (54). Therefore, continuous ECG monitoring is advised when these drugs are used in cardiac patients. Due to limited access to certain medications in China, traditional Chinese medicine (TCM) continues to be widely used for COVID-19 management. Although TCM has been temporarily included in medical insurance, efforts are ongoing to make it a long-term reimbursable option, particularly as it may help reduce progression to severe disease. Thromboembolic events are common in COVID-19, making prophylactic anticoagulation a critical component of care. Anticoagulation has been linked to lower mortality, decreased need for intubation, and a reduced risk of major bleeding compared to no anticoagulation. Since COVID-19 creates both hypercoagulable and hypofibrinolytic conditions, optimal anticoagulation strategies are still unclear due to limited definitive data (55).

An exaggerated immune response, particularly the cytokine storm, plays a significant role in the development of cardiovascular complications associated with SARS-CoV-2 infection (56). Immunomodulatory therapies such as IL-6 inhibitors and interferon β have been used to suppress proinflammatory cytokine levels by enhancing suppressor T cell activity, thereby mitigating immune-related damage in COVID-19 patients. Tocilizumab, an IL-6 receptor blocker, has shown effectiveness in improving symptoms and slowing clinical decline (57). However, its use is associated with elevated levels of HDL, LDL, and triglycerides, along with reduced hepatic LDL receptor expression, suggesting a potential risk for atherosclerosis and cardiovascular dysfunction (58). In severe cases, extracorporeal membrane oxygenation (ECMO), including veno-arterial-veno and veno-arterial configurations, has been successfully used to manage cardiogenic shock. Additionally, noninvasive respiratory support such as high-flow nasal cannula and positive pressure ventilation has proven effective, particularly where mechanical ventilation is limited. Regardless of the intervention used, it is critical to consider existing comorbidities and possible complications in patient management.

Vaccination preventive strategy

Prevention remains the most effective approach in combating COVID-19, with vaccination serving as a critical frontline defense, especially for vulnerable populations. Vaccines have significantly reduced cardiovascular complications by 26%–35% and lowered mortality rates by 43% (59). Similarly, influenza vaccination has shown cardiovascular benefits, particularly in patients with recent myocardial infarction, reducing associated risks by up to 55%. Governments worldwide prioritized vaccine distribution to healthcare workers and at-risk groups, although global shortages remain a challenge even under optimistic projections (60). COVID-19, caused by SARS-CoV-2, affects multiple organs, with the virus disrupting the renin-angiotensin-aldosterone system (RAAS) and damaging endothelial cells, which contributes to acute coronary syndrome (ACS), acute myocardial infarction (AMI), and chronic cardiovascular disease. Despite vaccination efforts, emerging variants such as Omicron pose a threat by reducing vaccine efficacy (61). Nevertheless, current vaccines continue to offer vital protection by eliciting broad immune responses. Widespread immunization remains the most promising global strategy to control the pandemic and prevent future outbreaks.

Future Directions

Viral infections such as myocarditis and heart failure deeply impact cardiovascular health, yet many aspects of this interaction remain unclear. To advance understanding and care, a focused research agenda is needed on the genetic and epigenetic underpinnings of virus-triggered cardiovascular disease.

Genome-wide association studies (GWAS)

GWAS compare genomes of affected versus unaffected individuals to identify disease-associated variants like SNPs. These studies have linked ACE2 variants to severe COVID-19 outcomes (62), and uncovered loci related to heart failure and coronary artery disease. However, few GWAS specifically explore virus-induced cardiovascular conditions. For instance, PCSK9 variants have been tied to cholesterol and coronary disease (63), but their role in viral heart disease is still under-studied. A Mendelian randomization study identified specific variants (e.g., rs505922, rs2277732) linking COVID-19 severity to cardiovascular mortality, suggesting potential genetic mechanisms like ACE2-mediated injury (64).

Epigenome-wide association studies (EWAS)

Epigenome-wide association studies (EWAS) detect epigenetic changes such as DNA methylation and histone modifications that influence disease processes (65). Heart failure EWAS have identified methylation patterns associated with disease severity (66), and recent EWAS in COVID-19 myocarditis patients have revealed specific epigenetic markers related to disease progression (67). These findings suggest that viral infection can lead to lasting epigenetic changes impacting cardiovascular health.

Integrated omics approaches

Combining GWAS and EWAS data offers insight into how genetic predispositions and epigenetic changes interact to affect disease susceptibility (68). Similar integrative methods in autoimmune diseases have already revealed multi-layered risk factors (69), and applying such approaches to virus-induced cardiovascular diseases could uncover new biomarkers and therapeutic targets. Further integrating transcriptomics, proteomics, metabolomics, and spatial omics is vital to capture the complexity of gene regulation, inflammation, metabolism, and tissue-specific responses(70). For example, at the 1p13.3 locus, genes like CELSR2-PSRC1 impact LDL levels, and variants in genes such as KLKB1 affect vasodilation and coronary risk (71).

Technological and ethical considerations

Single-cell and spatial omics technologies allow cellular-level resolution but face challenges in sensitivity, sample prep artifacts, and data interpretation. Integrating large-scale omics data also raises ethical and legal questions around privacy and equitable data sharing, and requires substantial funding, often limiting access to well-resourced institutions (72).

Interdisciplinary collaboration

Closing the gap between virology and cardiovascular research is crucial. Combining expertise across virology, immunology, molecular biology, and cardiology enables identification of viral mechanismssuch as oxidative stress, inflammation, and tissue tropismand how they exacerbate cardiovascular disease**(73)**. Such collaborative efforts are essential for developing new diagnostics (e.g., multi-omics biomarkers), personalized treatments, and effective prevention strategies **(74)**.

CONCLUSION AND DISCUSSION

The COVID-19 pandemic, caused by the severe acute respiratory syndrome-Coronavirus-2 (SARS-CoV-2), presented an unprecedented global health challenge due to its high infectivity and ability to transmit even during asymptomatic phases, leading to rapid worldwide spread. Beyond the initial respiratory distress, a critical aspect of COVID-19's impact has been its diverse and significant cardiovascular complications, affecting patients acutely and with long-term consequences. These include myocardial injury, arrhythmias, heart failure, vascular dysfunction, and thromboembolic events, with an elevated risk of acute myocardial infarction and ischemic stroke. The pervasive nature of these complications underscores the necessity of integrating cardiovascular care into comprehensive COVID-19 management strategies. The pathophysiology of SARS-CoV-2 infection is rooted in its interaction with the host's angiotensin-converting enzyme 2 (ACE2) receptor, abundantly present in the cardiovascular system. This interaction, coupled with a dysregulated ACE/ACE2 system and exacerbated by pre-existing conditions like hypertension, contributes significantly to cardiovascular damage. The virus also triggers a systemic inflammatory response, or "cytokine storm," involving pro-inflammatory cytokines like IL-6, which can directly injure the myocardium, promote plaque instability, and create a pro-thrombotic environment. Histopathological findings in severe cases often reveal microthrombi and cardiomyocyte necrosis, even in the absence of classic myocarditis, indicating widespread cardiac involvement. Endothelial dysfunction, particularly in the coronary microvasculature, further contributes to these issues by promoting inflammation and impairing vascular integrity.

The cardiovascular sequelae of COVID-19 are extensive and contribute significantly to patient morbidity and mortality. Elevated cardiac biomarkers, such as troponin and NT-proBNP, are common and serve as strong predictors of poor prognosis. Echocardiographic studies have frequently identified various forms of cardiac dysfunction, including right and left ventricular abnormalities. Myocarditis, though variable in prevalence, remains a serious concern, often occurring alongside respiratory symptoms but also presenting with delayed onset. The pandemic also drastically altered the landscape of acute coronary syndrome (ACS) care, leading to reduced admissions but increased in-hospital mortality, compounded by a direct increase in ACS risk post-infection due to inflammatory and pro-thrombotic mechanisms. Similarly, heart failure (HF) admissions were impacted, and COVID-19 infection itself was a strong predictor for acute HF and worse outcomes. A notable feature has been the heightened risk of thromboembolic events, including deep vein thrombosis and pulmonary embolism, driven by a hypercoagulable and hypofibrinolytic state induced by the virus. Furthermore, a significant proportion of COVID-19 survivors experience "Long COVID," characterized by persistent cardiovascular symptoms like fatigue, chest pain, and palpitations, underscoring the potential for long-term cardiovascular burden.

Current treatment strategies for COVID-19, especially in the presence of cardiovascular disease, emphasize a multidisciplinary, supportive, and symptomatic approach due to the limited direct antiviral options. Antiviral medications like Paxlovid and Remdesivir are used, alongside anti-inflammatory treatments such as corticosteroids and immunomodulatory therapies like IL-6 inhibitors, though careful monitoring for cardiovascular side effects is essential. Traditional Chinese Medicine has also played a role in management. Prophylactic anticoagulation is a critical component of care given the high incidence of thromboembolic events. In severe cases, advanced life support like ECMO and non-invasive respiratory support are employed. Prevention, however, remains the most effective strategy, with widespread vaccination significantly reducing both the overall severity of COVID-19 and its cardiovascular complications, highlighting its crucial role in controlling the pandemic. Looking ahead, advancing our

understanding of virus-triggered cardiovascular disease requires a focused research agenda. This includes leveraging genome-wide association studies (GWAS) to identify genetic predispositions and epigenome-wide association studies (EWAS) to uncover epigenetic changes influencing disease progression. Integrating these "omics" approaches with transcriptomics, proteomics, and metabolomics will provide a holistic view of the complex molecular interactions. Addressing technological challenges in data analysis and ethical considerations surrounding data sharing will be paramount. Ultimately, fostering robust interdisciplinary collaboration across virology, immunology, and cardiology will be crucial to translate these scientific advancements into novel diagnostics, personalized treatment strategies, and effective preventive measures against current and future viral threats to cardiovascular health.

ABSTRACT

Laghu Gangadhar Charna is a traditional Ayurvedic Formulation detailed in *Rasa Tantra Sara Siddha PrayogaSangraha*, commonly utilized for treating gastrointestinal issues like *Atisara* (diarrhea) and Grahani (malabsorption syndrome). The formulation includes powerful herbal components recognized for their *Deepana* (digestive), *Pachana* (carminative) and *Grahi* (absorbent) characteristics. This review seeks to gather and evaluate traditional references alongside contemporary pharmacological research of its components. Multiple research studies indicate that the individual components exhibit anti-diarrheal, antimicrobial, anti-inflammatory, and digestive properties. The combined effect of these herbs aids in reestablishing *Agni* (digestive fire) and regulating intestinal function. This assessment underscores the medicinal significance of *Laghu Gangadhara Churna* and stresses the necessity for additional clinical studies

Keywords: Laghu Gangadhar Churna, Atisara, Grahani, Ayurveda, Anti-diarrheal, Deepana, Pachana

INTRODUCTION

Gastrointestinal disorders such as *Grahani* and *Atisara* are commonly encountered in clinical practice and significantly impact quality of life. According to Ayurveda, these conditions primarily arise due to impairment of *Agni* (digestive fire), leading to improper digestion (*Ajeerna*) and formation of *Ama. Grahani*, considered one of the

Mahagadas, is the seat of Agni and plays a crucial role in retaining food until proper digestion; however, in the state of *Agnimandya*, it fails to perform this function, resulting in the passage of undigested food and manifestation of *Atisara* (diarrhoea) due to *Agnidosha*.[1] In this context, classical Ayurvedic formulations like *Laghu Gangadhar Churna*, described in Rasa Tantra Sara Siddha Prayoga Sangraha, are highly significant, as they possess *Grahi* (absorbent) and *Deepana-Pachana* properties, helping to restore digestive balance and effectively manage intestinal disorders such as diarrhea, dysentery, and malabsorption.[2]

Aim and Objectives

- To review classical references of *LaghugangadharChurna*
- To analyzepharmacognostical details of its ingredients
- To evaluate pharmacological activities based on modern research
- To correlate Ayurvedic principles with contemporary findings

MATERIALS AND METHODS

Drugre view:

LaghugangadharaChurna is a fine powder prepared by adding and mixing homogeneneously in the total 6 ingredients. All ingredients are taken in equal quantity that is 1 part. *LaghugangadharChurna*is described as a powdered formulation (*Churna*) used primarily in gastrointestinal disorders.

Pharmacognostical Description

The pharmacognostical evaluation of the ingredients of *LaghugangadharChurna* is essential for ensuring the identity, purity, and quality of the formulation. Each drug possesses distinct macroscopic and microscopic characteristics.

***Musta* (*Cyperus rotundus*)** consists of small, hard, dark brown to black rhizomes with a characteristic aromatic odor and slightly bitter taste. Microscopically, it shows a well-developed cortex, scattered vascular bundles, and abundant starch grains, which are responsible for its medicinal properties.[9]

***Bilva* (*Aegle marmelos*)** fruit pulp is yellowish to orange in color with a mucilaginous texture and a characteristic sweet-astringent taste. It contains numerous fibers, mucilage, and tannin-rich cells, which contribute to its *Grahi* (absorbent) and anti-diarrheal action.[10]

***Kutaja*(*Holarrhenaantidysenterica*)** bark appears grayish-brown externally and yellowish internally with a rough surface and bitter taste. Microscopic features include cork cells, stone cells, and laticiferous tissues, along with the presence of alkaloids, which are responsible for its anti-dysenteric activity.[11]

***Mochrasa*(*Bombax ceiba*)** is a reddish-brown exudate obtained from the bark, which becomes brittle upon drying. It is rich in tannins and mucilage and shows amorphous masses under microscopic examination. These properties contribute to its astringent and healing actions.[12]

***Lodhra*(*Symplocos racemosa*)** bark is grayish-brown externally and pale internally with a smooth texture and astringent taste. Microscopically, it shows thick-walled fibers, sclereids, and abundant tannin content, which play a key role in its *Stambhana*(astringent) effect.[13]

***Dhataki*(*Woodfordiafruticosa*)** flowers are small, bright red, and tubular with a slightly astringent taste. They contain abundant tannins, flavonoids, and pollen grains. Microscopic analysis reveals epidermal cells and vascular tissues, contributing to its Grahi and anti-inflammatory properties.[14]

Pharmacological activity of *LaghugangadharChurna*:

***Deepana–Pachana* (Improvement of Agni):**

The ingredients *Musta, Bilva, and Kutaja* play a significant role in enhancing digestive function through their *Deepana* (appetizer) and *Pachana* (digestive) properties.[15] Owing to the predominance of *Tikta* (bitter) and *Katu*(pungent) Rasa, these drugs stimulate digestive enzymes and improve gastrointestinal metabolism. They help in correcting *Mandagni* (diminished digestive fire), which is considered the primary cause of disorders like *Atisara* and *Grahani*in Ayurveda. Additionally, these herbs facilitate the digestion and elimination of *Ama* (metabolic toxins), thereby preventing its accumulation in the gastrointestinal tract. As a result, proper digestion is restored, and the formation of further toxic metabolites is effectively inhibited.

***Grahi* (Absorbent Action):**

The drugs *Bilva, Kutaja, Lodhra,* and *Dhataki* exhibit potent *Grahi* (absorbent) properties primarily due to their *Kashaya* (astringent) *Rasa.* This astringency helps in absorbing excess fluid from the intestinal lumen and enhances the absorptive capacity of the gut.[16] By reducing intestinal hypersecretion and improving consistency of stool, these drugs play a crucial role in controlling diarrhea. Thus, *Grahi* action contributes significantly to the normalization of bowel movements in conditions like *Atisara* and *Grahani.*

***Stambhana* (Astringent and Anti-diarrheal Effect):**

Kutaja, Mochrasa, Lodhra, and *Dhataki*possess strong *Stambhana* (checking or restraining) properties, which help in arresting excessive bowel movements. Their *Kashaya Rasa* acts on the intestinal mucosa by causing constriction and reducing excessive secretions.[17]This leads to decreased intestinal motility and fluid loss. Consequently, these drugs effectively control the frequency and severity of diarrhea and are particularly useful in managing dysentery and chronic intestinal disorders.

***Krimighna*(Antimicrobial Action):**

Musta and *Kutaja* are known for their *Krimighna*(antimicrobial) properties, which help in eliminating pathogenic microorganisms responsible for gastrointestinal infections.[17] These drugs inhibit the growth of harmful bacteria and parasites in the intestines, thereby addressing one of the root causes of *Atisara.* By reducing microbial load, they aid in restoring normal gut flora and improving overall intestinal health.

Anti-inflammatory and Mucosal Healing Action:

Lodhra,[18]*Mochrasa*,[19]and *Dhataki*[20]contribute to the anti-inflammatory and healing processes within the gastrointestinal tract. Due to their *Sheeta Virya* (cooling potency) and *Kashaya Rasa*, they help reduce inflammation and irritation of the intestinal mucosa. Additionally, they promote tissue healing and repair, which is essential in conditions involving mucosal damage such as chronic diarrhea and dysentery. This action helps in restoring the integrity and function of the intestinal lining.

Dosha Balancing Action:

The overall formulation predominantly pacifies *Kapha* and *Pitta Doshas*, which are mainly involved in the pathogenesis of *Atisara* and *Grahani*. The combination of *Tikta, Katu*, and *Kashaya Rasa* along with *Sheeta Virya* helps in maintaining doshic balance. By correcting the underlying doshic disturbances, the formulation supports normal physiological functioning of the digestive system and prevents recurrence of the disease.

DISCUSSION

LaghugangadharChurna, described in *Rasatantra Sara Siddha PrayogaSangraha*, is a well-established polyherbal formulation indicated in the management of *Atisara* (diarrhea) and *Grahani*(malabsorption syndrome). The formulation exhibits a multidimensional mode of action due to the synergistic combination of its ingredients. From an Ayurvedic perspective, the pathogenesis of *Atisara* and *Grahani*is primarily associated with *Mandagni*(impaired

digestive fire) and the formation of *Ama* (undigested metabolic toxins). The ingredients such as Musta, *Bilva,* and *Kutaja* possess Deepana and Pachana properties, which help in restoring *Agni* and promoting proper digestion. This action prevents the formation and accumulation of *Ama,* thereby addressing the root cause of the disease. The predominance of Kashaya Rasa in drugs like *Bilva, Kutaja, Lodhra,* and *Dhataki* contributes significantly to the *Grahi* (absorbent) and *Stambhana*(astringent) actions of the formulation. These properties help in reducing intestinal secretions, enhancing absorption, and controlling the frequency of loose stools. *Mochrasa* further supports this action due to its strong astringent and mucosal protective properties. In addition to these effects, *Kutaja*and *Musta* exhibit *Krimighna*(antimicrobial) activity, which plays an important role in managing infective diarrhea. Modern pharmacological studies have demonstrated that these drugs possess antimicrobial, anti-diarrheal, and anti-inflammatory properties, which correlate well with their traditional Ayurvedic uses. The presence of tannins, alkaloids, and flavonoids in these herbs contributes to their therapeutic efficacy by reducing intestinal motility, inhibiting microbial growth, and promoting mucosal healing.

Furthermore, drugs like *Lodhra*, *Mochrasa*, and *Dhataki* aid in reducing intestinal inflammation and enhancing tissue repair due to their *Sheeta Virya* and *Kashaya Rasa*. This helps in restoring the structural and functional integrity of the intestinal mucosa, which is often compromised in chronic conditions like *Grahani.* The formulation also plays a role in balancing Doshas, particularly *Kapha* and *Pitta*, which are predominantly involved in gastrointestinal disorders. By correcting *Dosha* imbalance and improving *Agni*, *LaghugangadharChurna* provides a holistic approach to disease management. Thus, the therapeutic efficacy of *Laghugangadhar*Churna can be attributed to its combined actions of *Deepana-Pachana*, *Grahi*, *Stambhana*, *Krimighna,* and anti-inflammatory effects. The integration of classical Ayurvedic principles with modern pharmacological evidence highlights its potential as an effective and safe remedy for gastrointestinal disorders. However, further clinical studies are required to validate its efficacy and establish standard treatment protocols.

CONCLUSION

LaghugangadharChurna represents a rationally designed Ayurvedic polyherbal formulation with multidimensional therapeutic actions in gastrointestinal disorders. Its efficacy is attributed to the synergistic interaction of ingredients exhibiting *Deepana-Pachana, Grahi*, *Stambhana*, antimicrobial, and anti-inflammatory properties. The formulation effectively addresses the underlying pathophysiology of *Atisara*and *Grahani*by correcting *Agni*, eliminating *Ama*, and restoring intestinal integrity. Correlation with modern pharmacological findings further strengthens its clinical relevance. Nevertheless, systematic clinical trials and standardization studies are essential to establish its safety, efficacy, and global acceptance in contemporary healthcare.

ABSTRACT

Self-healing polymeric nanocomposite hydrogels have emerged as a promising class of biomaterials owing to their ability to autonomously repair structural damage while providing enhanced mechanical, biological, and therapeutic functionalities. The integration of nanomaterials within hydrogel networks further improves their physicochemical properties, making them attractive candidates for advanced drug delivery and tissue regeneration applications. This review aims to provide a comprehensive overview of

the molecular mechanisms, fabrication strategies, structure–property relationships, drug delivery capabilities, and regenerative applications of self-healing polymeric nanocomposite hydrogels. Relevant literature focusing on self-healing hydrogels, nanocomposite systems, dynamic crosslinking mechanisms, fabrication technologies, drug delivery platforms, and tissue engineering applications was critically analyzed and synthesized. Particular emphasis was placed on recent advancements in hydrogel design and biomedical performance. Self-healing nanocomposite hydrogels exhibit improved mechanical strength, injectability, healing efficiency, drug-loading capacity, and stimuli-responsive behavior. Reversible interactions such as dynamic covalent bonds, ionic interactions, hydrogen bonding, and host–guest complexation play a crucial role in network reconstruction. Furthermore, these hydrogels have demonstrated considerable potential in controlled drug delivery, wound healing, bone regeneration, cartilage repair, cardiac repair, neural regeneration, and vascularized tissue engineering. The combination of self-healing capability and nanocomposite engineering has enabled the development of multifunctional hydrogel systems with significant therapeutic potential. Continued advancements in material design and translational research are expected to facilitate their future clinical application in regenerative medicine and precision drug delivery.

Keywords: Self-healing hydrogels; Nanocomposite hydrogels; Drug delivery; Tissue regeneration; Dynamic crosslinking; Regenerative medicine.

INTRODUCTION

Evolution of hydrogels in biomedical applications

Hydrogels are three-dimensional hydrophilic polymeric networks capable of absorbing substantial amounts of water while maintaining structural stability. Their biocompatibility, tunable properties, and tissue-like characteristics have made them valuable biomaterials for various biomedical applications [1,2]. Initially, hydrogels were utilized in contact lenses and wound dressings because of their ability to provide a moist environment and support tissue healing [3]. Advances in polymer chemistry and crosslinking strategies have enabled the development of hydrogels with improved mechanical strength, biodegradability, and stimuli responsiveness [4,5]. Consequently, hydrogels are now widely employed in drug delivery, tissue engineering, regenerative medicine, and cell therapy [6]. The emergence of smart, injectable, self-healing, and nanocomposite hydrogels has further enhanced their therapeutic potential and clinical relevance [7,8].

Significance of self-healing properties in biomedical hydrogels:

Despite their widespread biomedical applications, conventional hydrogels often suffer from poor mechanical resilience and irreversible structural damage when subjected to physiological stresses, limiting their long-term therapeutic performance [1,2]. To address these challenges, self-healing hydrogels have emerged as advanced biomaterials capable of restoring their structural integrity through dynamic and reversible interactions after mechanical disruption [9,10]. Such self-repairing behaviour is commonly achieved through dynamic covalent bonds, hydrogen bonding, ionic interactions, host–guest complexation, and hydrophobic associations [11,12]. The incorporation of self-healing capability significantly improves hydrogel durability, injectability, and adaptability within complex biological environments [5,6]. These characteristics are particularly beneficial for minimally invasive drug delivery systems and tissue engineering scaffolds, where repeated deformation and mechanical stress are unavoidable [13]. Furthermore, self-healing hydrogels can mimic the dynamic nature of the extracellular matrix, thereby supporting cell proliferation, migration, and tissue regeneration [7,14]. Owing to their ability to combine structural stability with biological functionality, self-healing hydrogels have become promising candidates for next-generation regenerative therapies and controlled drug delivery applications [8,15].

Role of nanocomposites in functional enhancement:

The integration of nanomaterials into hydrogel matrices has led to the development of nanocomposite hydrogels with significantly enhanced physicochemical and biological properties. Conventional hydrogels often exhibit limited mechanical strength, poor stability, and restricted functionality, which can hinder their performance in demanding biomedical applications [2,4]. The incorporation of nanoparticles, nanofibers, nanosheets, and other nanostructured materials can reinforce the hydrogel network, improve mechanical resilience, and impart additional functionalities such as antimicrobial activity, antioxidant properties, conductivity, and stimuli responsiveness [7,16]. Furthermore, nanocomposite hydrogels offer increased drug-loading capacity and improved control over therapeutic release profiles, thereby enhancing treatment efficacy [5,15]. By combining the structural adaptability of self-healing hydrogels with the multifunctional attributes of nanomaterials, nanocomposite hydrogels have emerged as promising platforms for advanced drug delivery, tissue regeneration, and precision biomedical applications [17,18].

Scope and novelty of this review:

This review comprehensively examines the design, self-healing mechanisms, and functional attributes of polymeric nanocomposite hydrogels for drug delivery and tissue regeneration. Unlike previous reviews, it emphasizes structure–property relationships, multifunctional therapeutic performance, emerging fabrication technologies, translational challenges, and future prospects, providing an integrated perspective on their clinical potential [16,18].

Molecular Basis of Self-Healing Hydrogels

Self-healing hydrogels possess the intrinsic ability to restore their structural integrity after physical or mechanical damage through reversible molecular interactions. This unique characteristic is governed by dynamic bonding mechanisms that enable network reconstruction under physiological conditions. Understanding these molecular interactions is essential for designing hydrogels with enhanced durability, adaptability, and therapeutic performance.

Dynamic covalent interactions:

Dynamic covalent interactions play a crucial role in the development of self-healing hydrogels by enabling reversible bond formation and dissociation under physiological conditions. Unlike permanent covalent crosslinks, dynamic covalent bonds can break and reform in response to external stimuli, allowing the hydrogel network to recover its structural integrity after damage [19,20]. Common dynamic covalent chemistries employed in self-healing hydrogels include Schiff-base linkages, boronate ester bonds, disulfide bonds, and Diels–Alder reactions [9]. These interactions provide a balance between mechanical stability and network adaptability, thereby enhancing the durability and functionality of hydrogel systems [22]. Furthermore, dynamic covalent bonds can impart stimuli-responsive behaviour, enabling hydrogels to respond to changes in pH, temperature, redox conditions, or biological environments [23]. Owing to their reversible nature and tunable kinetics, dynamic covalent interactions have become a fundamental strategy for engineering self-healing hydrogels for drug delivery, tissue engineering, and regenerative medicine applications [24].

Noncovalent interactions:

Non-covalent interactions represent another important class of reversible bonding mechanisms that contribute to the self-healing behaviour of hydrogels. These interactions are generally weaker than covalent bonds but possess rapid reversibility, enabling efficient network reconstruction after mechanical damage [25,26]. Common non-covalent interactions include hydrogen bonding, ionic interactions, hydrophobic associations, metal–ligand coordination, and host–guest complexation [9]. The dynamic nature of these interactions allows hydrogel networks to dissipate mechanical stress while maintaining structural integrity and flexibility [28]. Additionally, non-covalent interactions can be combined with covalent crosslinking strategies to achieve an optimal balance between mechanical strength and self-healing efficiency [29]. Such hybrid networks exhibit enhanced injectability, biocompatibility, and responsiveness to physiological stimuli, making them attractive for biomedical applications [30]. Consequently, non-covalently crosslinked self-healing hydrogels have gained considerable attention as versatile platforms for drug delivery, tissue engineering, wound healing, and regenerative medicine.

utonomous and stimuli-responsive self-healing mechanisms:

Self-healing hydrogels can be broadly classified into autonomous and stimuli-responsive systems based on the mechanism governing network restoration. Autonomous self-healing hydrogels possess the inherent ability to repair structural damage without external intervention. This behaviour is primarily driven by dynamic reversible interactions that spontaneously reform after disruption, enabling rapid recovery of mechanical integrity under physiological conditions [31,32]. Such systems are particularly advantageous for long-term biomedical applications where continuous functionality is required.

In contrast, stimuli-responsive self-healing hydrogels require specific external or internal triggers to initiate the healing process. These stimuli may include changes in pH, temperature, ionic strength, light exposure, redox conditions, magnetic fields, or enzymatic activity [12,17]. Upon stimulation, reversible bonds within the hydrogel network undergo dissociation and reformation, facilitating structural reconstruction and functional recovery [14]. The combination of self-healing capability with stimuli responsiveness offers enhanced control over material performance and therapeutic outcomes. Consequently, these advanced hydrogel systems have attracted significant interest for applications in controlled drug delivery, tissue engineering, regenerative medicine, and smart biomedical devices, where adaptability and sustained functionality are essential [17].**Figure 1** illustrates the fundamental mechanisms responsible for self-healing behaviour in hydrogel networks.

Engineering Polymeric Nanocomposite Hydrogels

The engineering of polymeric nanocomposite hydrogels involves the strategic integration of nanomaterials within polymer networks to enhance their structural, mechanical, and biological performance. By combining the advantages of hydrogels and nanomaterials, these multifunctional systems can be tailored to achieve improved stability, therapeutic efficacy, and functionality for diverse biomedical applications.

Polymeric matrix selection:

The selection of an appropriate polymeric matrix is a critical factor in the design of self-healing nanocomposite hydrogels, as it directly influences their mechanical properties, biodegradability, biocompatibility, and therapeutic performance. Both natural and synthetic polymers have been extensively utilized to fabricate hydrogel networks with tailored characteristics [16,18]. Natural polymers such as chitosan, gelatin, alginate, hyaluronic acid, collagen, and cellulose derivatives are widely preferred due to their excellent biocompatibility, bioactivity, and resemblance to the native extracellular matrix [29]. These polymers can promote cell adhesion, proliferation, and tissue regeneration, making them particularly suitable for biomedical applications. Synthetic polymers, including polyethylene glycol (PEG), polyvinyl alcohol (PVA), polyacrylamide (PAAm), and poly(N-isopropylacrylamide) (PNIPAM), offer superior mechanical strength, controlled degradation, and reproducible physicochemical properties [30]. In many cases, hybrid systems combining natural and synthetic polymers are developed to achieve an optimal balance between biological functionality and structural stability [17]. Therefore, careful polymer selection serves as the foundation for engineering multifunctional nanocomposite hydrogels with enhanced self-healing capability, drug delivery efficiency, and regenerative potential [6].

Nanomaterial integration strategies:

The incorporation of nanomaterials into hydrogel matrices is a key strategy for enhancing the functionality and therapeutic performance of nanocomposite hydrogels. Various nanomaterials, including polymeric nanoparticles, metallic nanoparticles, silica nanoparticles, nano clays, carbon-based nanomaterials, and nanofibers, have been successfully integrated into hydrogel networks to impart unique physicochemical and biological properties [7,17]. The selection of a suitable nanomaterial largely depends on the intended biomedical application and desired functional characteristics.Several approaches have been employed to achieve effective nanomaterial integration. Physical entrapment involves dispersing nanoparticles within the hydrogel matrix during gel formation, providing a simple and efficient method for drug encapsulation and controlled release [31]. Alternatively, chemical conjugation enables covalent attachment of nanomaterials to polymer chains, resulting in improved stability and uniform distribution throughout the network [32]. In situ nanoparticle formation within preformed hydrogels has also gained

attention as it promotes strong interactions between the nanomaterials and polymer matrix [17]. The incorporation of nanomaterials can significantly improve mechanical strength, self-healing efficiency, drug-loading capacity, antimicrobial activity, electrical conductivity, and stimuli responsiveness [12]. Furthermore, synergistic interactions between nanomaterials and polymeric networks facilitate the development of multifunctional hydrogel systems capable of addressing complex biomedical challenges. Consequently, nanomaterial integration has become a fundamental aspect of engineering advanced self-healing nanocomposite hydrogels for drug delivery, tissue regeneration, and precision therapeutic applications [14].

Hydrogelnanoparticle interactions:

The performance of polymeric nanocomposite hydrogels is strongly influenced by the nature of interactions between the hydrogel matrix and incorporated nanoparticles. These interactions govern the structural organization, mechanical properties, stability, and biological functionality of the resulting nanocomposite system [17]. Depending on the composition of the hydrogel and nanomaterial, interactions may occur through hydrogen bonding, electrostatic attraction, van der Waals forces, hydrophobic interactions, or covalent linkages [32]. Effective hydrogel–nanoparticle interactions facilitate uniform nanoparticle distribution within the polymer network, preventing aggregation and ensuring consistent material performance [7]. Furthermore, these interactions contribute to enhanced mechanical strength and self-healing efficiency by serving as additional crosslinking points that reinforce the hydrogel structure [12]. In drug delivery applications, nanoparticle–polymer interactions can improve drug encapsulation, protect therapeutic agents from premature degradation, and provide sustained release profiles [18].

The strength and reversibility of these interactions also influence cellular responses, degradation behaviour, and overall biocompatibility. Therefore, understanding and optimizing hydrogel–nanoparticle interactions is essential for the rational design of multifunctional nanocomposite hydrogels with improved therapeutic efficacy and regenerative potential for advanced biomedical applications [14].

Fabrication technologies:

The fabrication of self-healing polymeric nanocomposite hydrogels plays a crucial role in determining their structural characteristics, functional performance, and biomedical applicability. Various fabrication approaches have been developed to achieve precise control over hydrogel architecture, nanoparticle distribution, and therapeutic functionality [12,17]. Figure 2 illustrates the major fabrication approaches used to develop self-healing nanocomposite hydrogels. These strategies enable controlled hydrogel formation, nanoparticle incorporation, and network engineering, thereby enhancing self-healing performance and biomedical functionality.

Injectable hydrogel systems

Injectable hydrogels are among the most widely investigated platforms due to their minimally invasive administration and ability to conform to irregular tissue defects. These systems undergo gelation after injection, enabling localized drug delivery and tissue regeneration while preserving self-healing capability [12].

***In situ* gelation**

In situ gelation involves the formation of hydrogels directly at the target site through physical or chemical crosslinking mechanisms. This approach enhances retention at the implantation site and allows efficient encapsulation of therapeutic agents and nanoparticles within the hydrogel network [18,31].

Three-dimensional (3D) bioprinting

Recent advances in 3D bioprinting have facilitated the fabrication of hydrogels with complex architectures and controlled porosity. Self-healing nanocomposite hydrogels are particularly attractive bioinks because of their shear-thinning behaviour, injectability, and structural recovery following printing [14].

Microfluidic assisted fabrication

Microfluidic technologies enable the precise manipulation of polymers and nanoparticles, resulting in highly uniform hydrogel systems with controlled physicochemical properties. Such approaches improve reproducibility and facilitate the development of advanced multifunctional hydrogels for biomedical applications [7]. Collectively, these fabrication technologies provide versatile strategies for engineering self-healing nanocomposite hydrogels with enhanced therapeutic and regenerative capabilities.

Structure–Property Relationships

The therapeutic performance of self-healing polymeric nanocomposite hydrogels is closely associated with their structural characteristics and resulting material properties. Parameters such as network architecture, crosslinking density, nanoparticle distribution, and polymer composition significantly influence mechanical behaviour, degradation, swelling, drug release, and biological performance, ultimately determining their suitability for biomedical applications.

Network architecture:

Network architecture is a fundamental determinant of the performance of self-healing polymeric nanocomposite hydrogels. The arrangement of polymer chains, crosslinking density, pore structure, and nanoparticle distribution collectively influence the physical, mechanical, and biological properties of the hydrogel system [4,18]. A well-organized network architecture provides structural stability while maintaining sufficient flexibility for self-healing and adaptive behavior [19,25]. The degree of crosslinking plays a critical role in controlling hydrogel characteristics. Highly crosslinked networks generally exhibit enhanced mechanical strength and reduced swelling, whereas loosely crosslinked structures offer greater flexibility, permeability, and self-healing efficiency [16,17]. Additionally, pore size and interconnectivity affect nutrient transport, cellular infiltration, and drug diffusion, which are essential for tissue engineering and controlled drug delivery applications [6]. The incorporation of nanoparticles further modifies network architecture by introducing additional physical or chemical interactions within the polymer matrix [17]. These interactions can reinforce the hydrogel structure, improve mechanical resilience, and enhance functional performance. Therefore, careful engineering of network architecture is essential for achieving an optimal balance between structural integrity, self-healing capability, and therapeutic effectiveness in advanced nanocomposite hydrogel systems [7,14].

Mechanical strength

Mechanical strength is a critical property of self-healing polymeric nanocomposite hydrogels, particularly for applications involving load-bearing tissues, injectable systems, and long-term implantation. Adequate mechanical stability ensures that the hydrogel can withstand physiological stresses while maintaining its structural and functional integrity [4,18].

Influence of Crosslinking Density

The mechanical behaviour of hydrogels is strongly influenced by crosslinking density. An increase in crosslinking generally enhances stiffness, tensile strength, and structural stability. However, excessive crosslinking may reduce flexibility and impair self-healing efficiency by limiting polymer chain mobility [16,19].

Role of Nanoparticle Reinforcement

The incorporation of nanoparticles can significantly improve the mechanical properties of hydrogel networks. Nanoparticles act as reinforcing agents by creating additional interaction sites within the polymer matrix, thereby increasing resistance to deformation and fracture [17]. Uniform nanoparticle distribution is essential for achieving effective stress transfer throughout the hydrogel structure.

Relationship with Self-Healing Performance

Mechanical strength and self-healing capability must be carefully balanced during hydrogel design. While stronger networks provide improved durability, highly rigid structures may hinder the dynamic interactions required for

efficient self-repair [12,25]. Therefore, optimizing network composition and nanoparticle content is essential for developing hydrogels that combine robust mechanical performance with effective self-healing behaviour, ultimately enhancing their suitability for advanced biomedical and regenerative applications [7,14].

Injectability

Injectability is a highly desirable characteristic of self-healing polymeric nanocomposite hydrogels, particularly for minimally invasive biomedical applications. Injectable hydrogels can be administered through syringes or catheters, reducing surgical interventions, minimizing patient discomfort, and enabling localized therapeutic delivery [12]. Following injection, the hydrogel rapidly recovers its structure through self-healing mechanisms, ensuring retention at the target site and maintaining functional performance. The injectability of a hydrogel is primarily influenced by its rheological properties, polymer composition, and crosslinking mechanism. Dynamic and reversible interactions within the hydrogel network facilitate shear-thinning behaviour, allowing the material to flow under applied stress during injection and subsequently regain its original structure once the stress is removed [19,25]. This unique behaviour enhances handling properties while preserving mechanical integrity and biological activity. Nanoparticle incorporation can further improve injectability by modulating network interactions and optimizing flow characteristics. Consequently, injectable self-healing nanocomposite hydrogels have gained considerable attention for drug delivery, tissue engineering, and regenerative medicine applications, where precise administration and adaptability to irregular tissue defects are essential for therapeutic success [17].

Swelling and degradation

Swelling and degradation are important properties that influence the performance of self-healing polymeric nanocomposite hydrogels in biomedical applications. The swelling behavior determines the ability of hydrogels to absorb and retain biological fluids, which affects nutrient transport, drug diffusion, and cellular interactions within the hydrogel matrix [4,5]. An appropriate swelling capacity is essential for maintaining a favorable microenvironment for tissue regeneration and sustained therapeutic delivery.The extent of swelling is governed by factors such as polymer composition, crosslinking density, pore structure, and nanoparticle incorporation. Highly crosslinked networks generally exhibit lower swelling ratios, whereas loosely crosslinked structures allow greater water uptake [16,17]. Nanoparticles can further modulate swelling behaviour by altering network interactions and structural stability [17]. Degradation behaviour is equally critical, as it determines the residence time of the hydrogel at the implantation site. Controlled degradation enables gradual replacement of the hydrogel by newly formed tissue while ensuring sustained therapeutic activity. Therefore, balancing swelling and degradation characteristics is essential for optimizing the functionality and long-term performance of nanocomposite hydrogels [6,14].

Healing efficiency

Healing efficiency is one of the most important parameters for evaluating the performance of self-healing polymeric nanocomposite hydrogels. It refers to the ability of a damaged hydrogel network to restore its original structural, mechanical, and functional properties after experiencing physical disruption. High healing efficiency is essential for maintaining long-term stability and therapeutic performance in biomedical applications where hydrogels are exposed to repeated mechanical stress, deformation, or environmental fluctuations [19,25]. The healing efficiency of a hydrogel is primarily governed by the nature and reversibility of the interactions present within the polymer network. Dynamic covalent bonds and reversible non-covalent interactions facilitate network reconstruction by enabling broken bonds to reform after damage [20,24]. The mobility of polymer chains also plays a critical role, as sufficient chain movement promotes effective contact between damaged surfaces and accelerates the healing process [16,17]. Nanoparticle incorporation can significantly influence healing efficiency by providing additional interaction sites and reinforcing the hydrogel network. Properly dispersed nanoparticles contribute to improved stress distribution and facilitate the re-establishment of network connections following damage [17]. However, excessive nanoparticle loading may restrict polymer chain mobility and reduce healing performance. Several factors, including healing time, temperature, pH, crosslinking density, and nanoparticle concentration, can affect the extent of recovery achieved by self-healing hydrogels [12]. Therefore, optimizing these parameters is crucial for developing nanocomposite hydrogels with rapid and efficient self-repair capabilities. Enhanced healing efficiency not only

prolongs material lifespan but also improves the reliability and effectiveness of hydrogel-based drug delivery systems and regenerative therapies [14].

Drug loading capacity

Drug loading capacity is a critical parameter that determines the therapeutic effectiveness of self-healing polymeric nanocomposite hydrogels. It reflects the ability of the hydrogel network to encapsulate and retain therapeutic agents while maintaining structural stability [5,18]. Drug loading is influenced by factors such as polymer composition, pore architecture, crosslinking density, and the presence of nanoparticles within the hydrogel matrix. The incorporation of nanoparticles can enhance drug loading capacity by providing additional binding sites and increasing the surface area available for drug adsorption or encapsulation [17]. Furthermore, interactions between the drug, polymer network, and nanoparticles contribute to improved drug retention and controlled release behavior. Therefore, optimizing hydrogel composition is essential for achieving high drug-loading efficiency and sustained therapeutic performance in biomedical applications [6,14].

Self-Healing Nanocomposite Hydrogels for Drug Delivery

Self-healing nanocomposite hydrogels have emerged as versatile drug delivery platforms capable of protecting therapeutic agents, enabling controlled release, and improving treatment efficacy. Their dynamic network structure and multifunctional properties support sustained, localized, and stimuli-responsive delivery for a wide range of biomedical applications.

Delivery of therapeutic agents

Self-healing nanocomposite hydrogels have gained significant attention as advanced platforms for the delivery of diverse therapeutic agents. Their highly hydrated three-dimensional networks provide a protective environment that facilitates the encapsulation and stabilization of drugs while minimizing premature degradation [5,18]. Owing to their self-healing nature, these hydrogels can maintain structural integrity following mechanical disruption, thereby ensuring sustained therapeutic performance. A wide range of therapeutic agents, including small-molecule drugs, proteins, peptides, growth factors, and nucleic acids, can be effectively incorporated within self-healing nanocomposite hydrogels [6,14]. The incorporation of nanoparticles further enhances loading efficiency and enables controlled interactions between the hydrogel matrix and encapsulated therapeutics. These interactions contribute to prolonged retention and regulated release profiles, improving treatment efficacy while reducing systemic side effects [17].

Furthermore, the injectable and adaptable characteristics of self-healing hydrogels allow localized delivery to target tissues, resulting in improved bioavailability and therapeutic outcomes. Consequently, self-healing nanocomposite hydrogels have emerged as promising carriers for advanced drug delivery applications, offering a versatile platform capable of accommodating a broad spectrum of therapeutic molecules [12].

Stimuli-responsive controlled drug release:

Stimuli-responsive self-healing nanocomposite hydrogels have emerged as intelligent drug delivery systems capable of releasing therapeutic agents in response to specific physiological or external triggers. This responsive behaviour enables precise control over drug release kinetics, thereby improving therapeutic efficacy while minimizing undesirable side effects [5,12]. The combination of self-healing capability and stimuli sensitivity allows these hydrogels to maintain structural stability while adapting to dynamic biological environments. Various stimuli, including pH, temperature, reactive oxygen species (ROS), and enzymatic activity, have been exploited to regulate drug release from hydrogel networks [4,6]. Changes in these physiological conditions can alter the hydrogel structure, trigger bond dissociation, or modify network permeability, facilitating the controlled release of encapsulated therapeutics [24]. Such responsiveness is particularly advantageous for site-specific drug delivery, as pathological tissues often exhibit unique microenvironmental characteristics compared to healthy tissues. The incorporation of functional nanoparticles further enhances stimulus sensitivity and release precision by providing additional responsive elements within the hydrogel matrix [17]. As a result, stimuli-responsive self-healing

nanocomposite hydrogels offer a promising approach for achieving personalized and targeted therapeutic interventions across a wide range of biomedical applications [14]. Figure 3 illustrates the major mechanisms governing drug release from self-healing nanocomposite hydrogels, including diffusion, swelling, degradation, nanoparticle-mediated release, and stimuli-responsive release.

Self-Healing Nanocomposite Hydrogels in Tissue Regeneration

Self-healing nanocomposite hydrogels have emerged as promising biomaterials for tissue regeneration owing to their ability to mimic the native extracellular matrix, support cellular activities, and provide sustained therapeutic functions. Their dynamic self-repair capability, combined with enhanced mechanical and biological properties, facilitates tissue repair and regeneration across a wide range of biomedical applications.Table 1 highlights the impact of nanoparticle incorporation on the structural, functional, and therapeutic properties of self-healing hydrogels.

Soft tissue regeneration:

Self-healing nanocomposite hydrogels have demonstrated significant potential in the regeneration of soft tissues, including skin, neural, and cardiac tissues. Their highly hydrated structure provides a favorable microenvironment that supports cell adhesion, proliferation, migration, and extracellular matrix deposition [29]. In wound healing applications, these hydrogels can maintain a moist environment, protect damaged tissues, and enable the localized delivery of therapeutic agents, thereby accelerating tissue repair [7]. The self-healing capability of these hydrogels ensures structural integrity even under repetitive mechanical stress, which is particularly important in dynamic tissues such as skin and myocardium [12]. Furthermore, the incorporation of bioactive nanoparticles can enhance antimicrobial activity, angiogenesis, and cellular signalling, contributing to improved regenerative outcomes [14]. In neural tissue engineering, self-healing hydrogels provide adaptable scaffolds that support neuronal growth and tissue integration. Similarly, in cardiac repair, their injectable and self-recovering properties facilitate minimally invasive administration and effective retention at the injury site. Consequently, self-healing nanocomposite hydrogels represent versatile platforms for promoting soft tissue regeneration and functional recovery following injury or disease [6,14].

Hard tissue regeneration:

Self-healing nanocomposite hydrogels have gained considerable attention in hard tissue regeneration, particularly for bone and cartilage repair. These tissues require biomaterials with adequate mechanical stability, biocompatibility, and the ability to support cellular growth and differentiation. The incorporation of nanoparticles within hydrogel networks enhances mechanical strength and provides structural support that closely resembles the native extracellular matrix [17]. In bone regeneration, self-healing hydrogels serve as injectable scaffolds capable of filling irregular defects while delivering bioactive molecules that promote osteogenesis. Their dynamic network structure enables adaptation to the surrounding tissue environment and facilitates long-term integration with newly formed bone [14]. Similarly, in cartilage regeneration, these hydrogels provide a hydrated and flexible matrix that supports chondrocyte proliferation and extracellular matrix production. The self-healing capability further improves durability under repetitive mechanical loading. Consequently, self-healing nanocomposite hydrogels have emerged as promising candidates for repairing and regenerating hard tissues while enhancing functional recovery and tissue integration [6,14].

Advanced tissue engineering applications:

The advancement of tissue engineering has increased the demand for biomaterials capable of supporting the regeneration of complex and highly organized tissues. Self-healing nanocomposite hydrogels have emerged as attractive candidates due to their ability to combine structural adaptability, biological functionality, and therapeutic delivery within a single platform [6,14]. One of the most significant applications involves vascularized tissue engineering, where the formation of functional blood vessel networks is essential for nutrient transport and long-term tissue survival. Self-healing hydrogels provide a supportive microenvironment that promotes cellular organization, angiogenesis, and tissue maturation [14]. Their dynamic network structure allows continuous remodeling, closely resembling the behavior of native extracellular matrices. In addition to vascularized tissues,

these hydrogels have shown potential for the development of complex tissue constructs involving multiple cell types and biological components. The incorporation of nanoparticles can further enhance mechanical properties, bioactivity, and controlled delivery of regenerative factors, thereby improving overall tissue development [17]. Furthermore, their injectable and self-repairing characteristics facilitate minimally invasive administration and improve scaffold longevity following implantation [12]. Collectively, these advantages position self-healing nanocomposite hydrogels as versatile platforms for next-generation tissue engineering strategies aimed at restoring tissue structure, functionality, and long-term biological integration.Table 2 summarizes representative applications of self-healing nanocomposite hydrogels in tissue regeneration, highlighting their functional roles and regenerative outcomes across different tissue types.

CONCLUSIONS AND FUTURE PERSPECTIVES

Self-healing polymeric nanocomposite hydrogels have emerged as dynamic therapeutic platforms with significant potential in drug delivery and tissue regeneration. Their unique ability to combine self-repairing behaviour, multifunctionality, and biological compatibility has expanded their biomedical applicability. Continued advances in material design, fabrication technologies, and translational research are expected to accelerate the development of clinically relevant hydrogel systems. Despite existing challenges, these materials represent a promising foundation for next-generation regenerative therapies and precision medicine approaches.

Key Advances and Current Limitations

Significant progress has been achieved in the development of self-healing nanocomposite hydrogels through the integration of dynamic crosslinking mechanisms and functional nanomaterials. These systems exhibit enhanced mechanical performance, controlled drug delivery capabilities, improved biological activity, and superior regenerative potential. Their ability to recover from mechanical damage has further expanded their utility in demanding biomedical environments. Despite these advancements, several limitations remain. Challenges related to large-scale manufacturing, reproducibility, sterilization, long-term safety, and regulatory approval continue to hinder clinical translation. In addition, balancing mechanical strength, self-healing efficiency, degradation behaviour, and therapeutic performance remains a complex design challenge that requires further investigation.

ACKNOWLEDGEMENT

The author would like to thank all the faculty members of KLE college of pharmacy, Hubballi for providing necessary support.

Conflict Of Interest

The authors declare that there is no conflict of interest.

Funding

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Ethical Statement

This study did not involve any human or animal subjects, and hence, ethical approval was not required.

Table 1. Effect of Nanoparticle Incorporation on Hydrogel Properties

Property	Effect of Nanoparticles	Significance
Mechanical strength	Improves stiffness and toughness	Enhances durability
Self-healing efficiency	Provides additional interaction sites	Promotes rapid repair
Swelling behaviour	Regulates water uptake	Controls diffusion and transport
Degradation	Modifies degradation rate	Supports sustained functionality
Drug loading	Increases loading capacity	Improves therapeutic delivery
Drug release	Enables controlled release	Enhances treatment efficacy
Injectability	Improves flow behaviour	Facilitates administration
Biocompatibility	Enhances cell interactions	Supports tissue regeneration
Bioactivity	Provides antimicrobial and antioxidant functions	Promotes healing
Stimuli responsiveness	Increases sensitivity to external stimuli	Enables targeted drug release

Table 2. Recent Applications of Self-Healing Nanocomposite Hydrogels in Tissue Regeneration

Tissue Type	Hydrogel System	Key Function	Regenerative Outcome
Skin/Wound	Self-healing nanocomposite hydrogel	Moist wound environment and drug delivery	Accelerated wound closure
Bone	Nanoparticle-reinforced hydrogel scaffold	Enhanced mechanical support and osteogenesis	Improved bone regeneration
Cartilage	Injectable self-healing hydrogel	Supports chondrocyte growth	Cartilage tissue repair
Cardiac	Conductive self-healing hydrogel	Promotes electrical signal transmission	Improved cardiac repair
Neural	Self-healing bioactive hydrogel	Supports neuronal growth and integration	Enhanced neural regeneration
Vascularized tissues	Multifunctional nanocomposite hydrogel	Promotes angiogenesis and tissue remodeling	Improved vascularized tissue formation

ABSTRACT

Sex determination in unidentified skeletons is not always easily and correctly performed by a non-specialist without formal training in forensic anthropology. In explosions, warfare and other mass disasters like aircraft crashes, identification may be extremely complicated because of skeletal fragmentation. Sexual dimorphism, the anatomical and physiological differences between males and females, has been a subject of extensive research in forensic and anthropological studies. This systematic review aims to consolidate and analyze existing literature on the measurement of two crucial anatomical structures, the foramen magnum and optical foramen, as potential indicators of sex dimorphism. The foramen magnum, a key opening at the base of the skull, and the optical foramen, an opening in the eye socket, are recognized as potential sites for observing sexual dimorphism due to their involvement in various physiological functions. Numerous studies have employed diverse measurement techniques, such as traditional anthropometric methods and advanced imaging technologies, to quantify size and shape differences between male and female populations. The current review systematically assesses the methodologies, sample sizes, and statistical approaches utilized in the selected studies. Additionally, it explores the reliability and validity of these measurements as indicators of sexual dimorphism. Special attention is given to variations among different populations, ethnic groups, and age categories, acknowledging the importance of considering diverse demographic factors in sex estimation. Furthermore, the review discusses the potential applications of sex dimorphism studies in forensic anthropology, paleoanthropology, and clinical settings. Understanding the inherent variations in

foramen magnum and optical foramen dimensions contributes not only to the field of biological anthropology but also holds implications for personalized medicine and forensic identification. By critically evaluating the existing body of literature, this systematic review provides valuable insights into the current state of knowledge regarding the measurement of foramen magnum and optical foramen for sex dimorphism. The findings underscore the need for standardized methodologies and highlight avenues for future research to enhance the accuracy and applicability of these anatomical features in sex estimation.

Keywords: Computed Tomography, Foramen Magnum, Optical foramen, Measurement, Sex dimorphism

INTRODUCTION

Sexual dimorphism, the morphological and physiological differences between males and females within a species, is a fundamental aspect of biological diversity. Foramen magnum anatomy help to anthropological and forensic contexts, the accurate determination of sex from skeletal remains is a crucial step in reconstructing the demographic profile of an individual. Over the years, researchers have explored various anatomical markers to discern these sex-based distinctions, with a growing focus on the foramen magnum and optical foramen as potential indicators.(1) The foramen magnum, situated at the base of the skull, plays a pivotal role in transmitting the spinal cord and facilitating the connection between the brain and the spinal column. Likewise optical foramen anatomy , an opening in the eye socket, serves as a conduit for the optic nerve and blood vessels. Both structures are integral to essential physiological functions, making them intriguing candidates for the study of sexual dimorphism.(2) This systematic review endeavors to comprehensively examine the existing body of literature surrounding the measurement of foramen magnum and optical foramen dimensions as potential discriminators between male and female individuals. By systematically collating and synthesizing relevant studies, we aim to provide a comprehensive overview of the methodologies employed, the populations studied, and the reliability of these measurements in sex estimation.

The significance of understanding sex-based variations in these anatomical features extends beyond the realms of anthropology, reaching into forensic science, paleoanthropology, and clinical applications. Accurate sex estimation from skeletal remains not only contributes to the reconstruction of past populations but also plays a vital role in contemporary forensic investigations and medical diagnostics.(3-4)As we embark on this systematic review, our objectives are to critically evaluate the methodologies employed in measuring foramen magnum and optical foramen, assess the reliability and validity of these measurements as indicators of sex, and highlight potential avenues for future research. Through this synthesis, we aspire to contribute valuable insights to the field, fostering a deeper understanding of the intricacies involved in utilizing these anatomical landmarks for sex dimorphism studies.(5-6)Moreover, the selection of the foramen magnum and optical foramen as focal points for sex estimation is grounded in their unique anatomical and functional characteristics. The foramen magnum, being the primary opening through which the spinal cord passes, undergoes intricate developmental processes that may exhibit sex-specific variations. Similarly, the optical foramen, which accommodates crucial neurovascular structures, may reflect sex-related distinctions in skeletal morphology.(7). The current state of research in this field reveals a diverse array of measurement techniques, ranging from traditional anthropometric calipers to advanced imaging technologies such as computed tomography (CT) scans and three-dimensional reconstructions. The choice of methodology can significantly impact the accuracy and reliability of sex estimation, prompting a critical evaluation of the strengths and limitations associated with each approach. Furthermore, the existing literature reflects a notable diversity in the populations studied, including variations in ethnicity, geographic origin, and chronological periods. Recognizing these demographic nuances is imperative for extrapolating findings to different populations and refining the applicability of sex estimation techniques across diverse groups.(8)In the forensic domain, the ability to accurately

determine the sex of an individual from skeletal remains holds immense practical significance. This review aims to elucidate the potential forensic applications of foramen magnum and optical foramen measurements, addressing their utility in medico-legal investigations, disaster victim identification, and the resolution of cold cases. Additionally, insights from paleo-anthropological perspectives can shed light on the evolutionary aspects of sexual dimorphism, contributing to our understanding of human population dynamics across time. As we delve into the systematic exploration of the literature, we will meticulously assess the statistical methodologies employed in sex dimorphism studies, emphasizing the importance of standardized protocols to enhance comparability across investigations. This review will also highlight gaps in existing research, paving the way for future studies to address unanswered questions and refine our understanding of the intricate relationship between foramen magnum and optical foramen dimensions and sexual dimorphism.[9]By synthesizing available evidence, we strive to provide a comprehensive overview that not only contributes to the academic discourse but also informs forensic practitioners, anthropologists, and medical professionals about the potential applications and limitations of utilizing these anatomical features in the determination of sex from skeletal remains.[10] The optic canal is the narrowest point of the optic nerve subarachnoid space.[25] As a watershed region for cerebrospinal fluid (CSF) flow, it has become a landmark of interest in ocular pathologies that involve the translaminar pressure difference (TLPD), including glaucoma and papilloedema from increased intracranial pressure (ICP) or space flight-associated neuro-ocular syndrome (SANS).[26-28]

Objectives

Objective: To estimate the foramen magnum is useful for gender determination, To estimate the optical foramen is useful for gender determination, Both foramen magnum and optical foramen helps for forensic expert for determination of both sexes.

MATERIAL METHODS

This study was done at department of medical radiology and imaging technology, Subharti College of allied and healthcare, swami Vivekanand subharti university, meerut, uttarpradesh, india. Article for review are taken from different research and journal websites like web of science, scopus, pubmed and different journal websites. After studying the different article, they were used Computed Tomography for measurement of foramen magnum and optical foramen. NCCT Head and CECT head patient was used for sample collection/ data collection. They were used convenient sampling for their study. They measured of foramen magnum and optical foramen length like AP and TR length as shown in figure: 1 and 2 . These are taken from department CT console. In above table: 1 states about differentiate among different researcher on different approaches, study sites, study part and study population. This data was taken from different journal website and pubmed etc. After analyzing the comparative table was created.

DISCUSSION

In this comprehensive review on Measurement of Foramen Magnum and Optical Foramen for Sex Dimorphism was done at department of medical radiology and imaging technology, subharti college of allied and healthcare, swami Vivekanand subharti university, meerut, uttar Pradesh west, india. This review objective is to measure the foramen magnum and optical foramen. Abtehag A Taib, et al.was concluded from their study that the commonest type was hexagonal which is followed by irregular type A. Foramen of monro parameters was smaller in females than males. Foramen magnum types and parameters was consider during surgical interventions and radiology reports.(11). Moodley M., et al. was describe that there was no relationship between foramen magnum shape and gender. They were observed simultaneously in 3 age categories suchas children, adolescents and adults. The common dimension in children was the oval shape 8.67%,(hexagonal 7.33), aldolism 10%, adults. Its minimum and maximum TR were and 23.75 mm 37.10 mm, respectively. The mean area was 800.637± 116.59 mm^2.The minimum and maximum areas of FM were 501.53 mm2 and 1132.96 mm2 , respectively. They conclude from their study that FM morphology showed only

a significant difference in age, not gender, of 4,444people. (12)Aghakhani K, et al. was observed that the transverse diameter of the foramen of monro and the area was greater in male than in female. Based on cut-off point for AP foramen magnum, transverse diameter, Teixeira formula and routal formula all these indicators, specificity and sensitivity was equal to 100% and 92% and all the individual have equal size or more of the value in men. 96% was overall accuracy of indicators was calculated as 85%. Finally they concluded from their study was using CT scan images, the foramen magnum diameter and its area was showed a high precision in sexual dimorphism.(13)Mayuri J., et al. was concluded from their study that there were higher averages of width, length, area and circumference of the foramen of monro in both cases and also found that gender in the area of the foramen of monro was additional reliably predicted. (14)Ayfer Metin T., et al.was provides indications that CT is used for anthropological studies, and indicates the standard area of the foramen of monro in the normal populace and suggests that the images can aidin the diagnostic procedure of some diseases.(15)

S. kumar, et al. was conclude from their study that the measurement of the antero posterior and transverse diameters of the foramen of monro and the frontal nasal angle was the most reproducible 3D technique. For 3D volume measurement, in view of software requirements, a fast and reliable tool for diameter measurement for physiological differences of foramen of monro and angular anterior nasal junction was considered useful for sex dimorphism in human skulls of the populance of southern India. (16)Harshita R., et al.concluded from their study that the two dimensions of the basioccipita and the foramen of monro were used precisely to evaluate sex. This opens up opportunities for new research in the field of the study of people and extremely careful, crime-solving, science-based medicine. (17)S. P. V., et al. was conducted a retrospective Study in year 2018 at the Radio Diagnosis department, Kempegowda IOMS, Bangalore, Karnataka, India on Computerized Tomo graphic Images and obtained approval for their research from the institutional ethics. According to the results of the Martin and Saller classification, the medium type foramen index was shown. The combined mean index was foundtobe 84.27 ± 8.35.For the foramen magnum index, a female was compared to the male, the foramen magnum index was elevated. They concluded from their study that the size and measurement of the foramen of monro were taken into account in operation sat the cranio-vertebral junction. It was also used for anthropological and forensic examinations of unknown persons. The foramen magnum determin essex, ethnicity. They state that multivariate analysis was the best method of sexing thes kull with the available resources.(18)RIA-K., et al.was conclude from their study that the dimension of the basioccipital and foramen of monro are larger in men and that the width of the foramen magnum and the length of the left occipital condyle are successful for sex dimorphism and a gross precision of 90% and an accuracy of 91.3% and 87.5. %were used inmen and women. (19)Radhakrishna S.K., et al.was received the result of their research that the oval shape was the mostssimilar, observed by round, pentagonal and tetragonal in both sexes. The transverse diameter (28.63 vs 26.59) and anteroposterior diameter was (34.04 vs 31.72) was remarkably greater in men than in women ($P<0.05$). Their research was concluded to give a statistically useful indication of the genus of the unspecified skull.(20)AT U., et al. was calculated from their study that for forensic study on sexual dimorphism measurement of foramen magnum was valuable. It tend to balance after life time of second and reconstructed computerized tomography scan was produce appropriate evaluation for their size.(21) Kumar A., et.al, wasonclude from their study was foramen magnum and fronto nasal junction was useful for sex determination in western up population. They found significant result from their study.(22)

CONCLUSION

Our review study provides valuable insights into the potential of these anatomical features for distinguishing between male and female skulls. Studies consistently show that the dimensions of the foramen magnum and optical foramen tend to exhibit sexual dimorphism, with males generally having larger measurements. However, the degree of sexual dimorphism varies across populations and methodologies used in different studies. While these measurements can be useful as part of a broader anthropological or forensic toolkit, they are not definitive on their own. Future research should focus on standardizing measurement techniques and expanding data collection across diverse populations to improve the accuracy and applicability of these metrics in sex estimation.

ABSTRACT

Increasing consumption of processed and ultra-processed foods (UPFs) among adolescents is a growing public health concern in India, contributing to rising non-communicable diseases (NCDs) [1,2]. However, rapid screening tools for assessing such consumption remain limited. To develop and validate an integrative screening tool for assessing processed and ultra-processed food consumption among adolescents. A cross-sectional study was conducted among 50 adolescents aged 10–18 years. Dietary intake was assessed using a Food Frequency Questionnaire based on NOVA classification and a 24-hour recall method. Content validity was assessed using Content Validity Index (CVI), and reliability was evaluated using Cronbach's alpha. Statistical analyses included descriptive statistics and chi-square tests. The tool demonstrated good internal consistency, with Cronbach's alpha values of 0.869 for processed foods and 0.913 for ready-to-eat ultra-processed foods. Moderate reliability was observed for beverages (α = 0.677). Content validity was moderate for ultra-processed food categories (CVI = 0.50–0.57), while initial validity for processed foods was lower (CVI = 0.268), which improved following item refinement. Significant gender differences were observed in the consumption of flavoured milk (p = 0.015), yogurt-based drinks (p = 0.007), fast food items (p = 0.032), and ice cream products (p = 0.024). The developed screening tool demonstrated preliminary evidence of validity and good reliability for assessing processed and ultra-processed food consumption among adolescents and can be applied in primary care and community settings.

Keywords: Ultra-processed foods, adolescents, NOVA classification, screening tool, validation, India

INTRODUCTION

Processed and ultra-processed foods have become a dominant component of modern diets due to rapid urbanization, industrialization, globalization, and changing food habits.[1] These foods are generally energy-dense and often contain excessive amounts of added sugars, sodium, saturated fats, preservatives, and additives, which contribute to poor dietary quality and increased risk of obesity, cardiovascular diseases, metabolic disorders, and other non-communicable diseases.[2,3] The NOVA food classification system categorizes foods according to the nature, extent, and purpose of industrial processing and has become an important framework for evaluating dietary patterns and food consumption behaviors.[4] Growing evidence indicates that higher intake of ultra-processed foods is associated with adverse health outcomes and unhealthy lifestyle behaviors among children and adolescents. [3,5] In India, dietary transitions among adolescents have accelerated due to changing food environments, increased exposure to packaged foods, aggressive food marketing strategies, and greater accessibility of convenience foods.[6]

Although commonly used dietary assessment methods such as food frequency questionnaires and 24-hour dietary recalls provide information regarding food intake patterns, these methods frequently fail to adequately capture the extent of food processing.[7]

Objectives

- To assess the consumption pattern of processed and ultra-processed foods among adolescents aged 10–18 years.
- To develop an integrative screening tool for assessing processed food consumption.
- To evaluate the validity and reliability of the developed screening tool.

METHODOLOGY

Study design and setting

A cross-sectional methodological study was conducted to develop and evaluate an integrative screening tool for assessing processed and ultra-processed food consumption among adolescents. Data collection was carried out across various schools in Bengaluru, India.

Study participants and sampling

Participants were recruited using convenience sampling based on predefined eligibility criteria. Adolescents aged 10–18 years who were willing to participate and provide assent/consent were included in the study. Participants with chronic illnesses, medically prescribed dietary restrictions, or incomplete dietary information were excluded.

Sample size

A pilot sample of 50 adolescents was included for preliminary evaluation of the validity and reliability of the developed screening instrument.

Dietary assessment procedures

Dietary intake was assessed using a Food Frequency Questionnaire (FFQ) developed according to the NOVA food classification framework and supplemented using a 24-hour dietary recall method. Food items were categorized into processed foods and ultra-processed foods based on the degree and purpose of industrial processing.

Development of scoring criteria

A frequency-based scoring system was developed to quantify food consumption patterns. Scores were assigned according to consumption frequency and cumulative scores were categorized into low, moderate, and high consumption groups.

Validation procedure

Content validity of the screening instrument was assessed by an expert panel comprising approximately 20 subject experts. Experts evaluated individual food items for relevance, clarity, appropriateness, and comprehensiveness. The Content Validity Index (CVI) was computed, and food items demonstrating lower validity scores were revised according to expert recommendations.[8]

Reliability assessment

Internal consistency of the tool was assessed using Cronbach's alpha coefficient.

Statistical analysis

Statistical analyses included descriptive statistics such as means, standard deviations, frequencies, and percentages. Associations between variables were assessed using chi-square tests. Statistical significance was considered at $p<0.05$.

Ethical considerations

Participation in the study was voluntary and informed consent/assent was obtained from participants and/or parents prior to data collection. Confidentiality and anonymity of participant information were maintained throughout the study.

RESULTS

Participant Characteristics

A total of 50 adolescents participated in the study, including 15 males (30%) and 35 females (70%). The mean age of participants was 15.28 ± 2.51 years. More than half of participants belonged to the 16–18 years age category, indicating greater representation of older adolescents

Anthropometric Measurements

in Table 2. Mean height, weight, and BMI values showed increasing trends with age. Mean BMI values largely remained within acceptable ranges according to age-specific anthropometric assessment standards recommended by the World Health Organization.[9] Slight variations were observed across sex groups.

Validity of the Tool

Content validity assessment demonstrated moderate validity for ultra-processed food categories, with CVI values ranging between 0.50 and 0.57. Initial validity for processed food categories was comparatively lower (CVI=0.268); however, item modifications and expert recommendations improved content appropriateness.

Consumption Patterns

Consumption pattern analysis based on Tables 5–12 demonstrated varying frequencies of processed and ultra-processed food intake among adolescents. Among processed foods, frequently consumed items included idli/dosa batter, snack products, and selected convenience foods. Consumption of ultra-processed foods was more common for beverages, ready-to-eat products, and fast-food items. Most food items showed no statistically significant gender differences; however, significant differences were observed for flavoured milk ($p=0.015$), yogurt-based beverages ($p=0.007$), fast foods ($p=0.032$), and ice cream products ($p=0.024$). These findings indicate variability in consumption patterns and highlight specific food categories requiring attention for dietary interventions.

Classification of Consumption

Participants were categorized into low, moderate, and high consumption groups based on scoring criteria, enabling identification of individuals at risk of excessive processed food intake.

Reliability of the Tool

Reliability analysis demonstrated acceptable to excellent internal consistency. The highest reliability was observed among ready-to-eat and ready-to-cook items (α=0.913), whereas beverage categories demonstrated moderate reliability (α=0.677). Processed food categories demonstrated good internal consistency (α=0.869).

DISCUSSION

The present study aimed to develop and evaluate an integrative screening tool for assessing processed and ultra-processed food consumption among adolescents. Findings indicate increasing consumption of processed and ultra-processed food products among adolescents, reflecting changing dietary behaviours and evolving food environments. Similar trends have been reported in previous studies demonstrating increased consumption of convenience foods and packaged products among adolescents due to urbanization, changing lifestyles, peer influence, and greater accessibility of commercially processed foods. [3,6]Such dietary transitions are concerning because adolescence represents a critical period during which long-term food preferences and dietary habits are established. Significant gender differences observed in flavoured milk products, yogurt-based beverages, fast foods, and ice cream products may reflect differences in food preferences, sociocultural influences, and dietary practices among adolescents.

The developed screening tool demonstrated good internal consistency and preliminary evidence of validity. Cronbach alpha values indicated strong reliability across major food categories. The expert review process involving approximately twenty experts strengthened content relevance and contributed to refinement of individual food items. The study has several limitations. The sample size was relatively small and participants were recruited using convenience sampling, which may limit generalizability. Dietary intake assessment relied partly on self-reported information and may therefore be susceptible to recall bias. Future studies involving larger and more diverse samples are required to further evaluate psychometric properties of the instrument. Despite these limitations, this study represents an initial effort toward development of a culturally relevant screening instrument for Indian adolescents that may facilitate rapid identification of unhealthy dietary patterns in school and community settings.

CONCLUSION

The present study developed a preliminary screening tool for assessing processed and ultra-processed food consumption among adolescents. The instrument demonstrated good reliability and preliminary evidence supporting validity, indicating its potential use as a rapid screening tool in school, community, and primary healthcare settings. Future studies involving larger populations are needed to establish broader applicability and strengthen psychometric evaluation.

ABSTRACT

To identify latent behavioral domains influencing diabetic retinopathy screening uptake among adults in Western Uttar Pradesh using exploratory factor analysis of knowledge, attitude, and practice variables. A community-based cross-sectional study was conducted among 352 adults residing in Western Uttar Pradesh, India. Data were collected using a structured interviewer-administered questionnaire assessing knowledge, attitude, and practice related to diabetes, hypertension, diabetic retinopathy, retinal examination, and healthcare utilization. Exploratory factor analysis was performed on 19 selected variables using Principal Component Analysis with Varimax rotation and Kaiser normalization. Factors with eigenvalues greater than 1 were retained. Descriptive statistics were used to summarize socio demographic and clinical characteristics. The mean age of participants was 53.70 ± 10.03 years, and 53.7% were females. Nearly half of the participants (45.2%) had no formal education. Diabetes alone was reported by 41.2% of participants, while 27.0% had both diabetes and hypertension. Exploratory factor analysis identified six latent behavioral domains explaining 61.47% of the total variance. The extracted domains included retinal examination and eye care utilization behavior, hypertension-related awareness, preventive diabetes care awareness, diabetic eye disease awareness, general medical care utilization, and need for continued ophthalmic care. The strongest factor loadings were observed for awareness of dilated retinal examination (0.853), uptake of dilated examination (0.823), knowledge regarding hypertension-related diabetic complications (0.831), and recent eye doctor visit history (0.717). Diabetic retinopathy

screening behavior is influenced by multiple interconnected awareness and healthcare utilization domains. Significant awareness-practice gaps exist, highlighting the need for targeted education and integrated retinal screening strategies in rural populations.

INTRODUCTION

Diabetes mellitus (DM) has emerged as one of the most important non-communicable diseases worldwide and represents a major public health challenge, particularly in low- and middle-income countries [1,2]. Rapid urbanization, lifestyle modification, population ageing, and reduced physical activity have contributed substantially to the increasing burden of diabetes in India and globally [2,3]. India currently harbors one of the largest populations of individuals with diabetes, and the prevalence is expected to increase further in coming decades, placing enormous pressure on healthcare systems and blindness prevention programs [4]. Among the numerous systemic complications of diabetes, diabetic retinopathy (DR) remains one of the leading causes of preventable blindness among working-age adults worldwide [1,4]. Diabetic retinopathy is a progressive microvascular complication resulting from chronic hyperglycemia and retinal vascular damage. If left undetected and untreated, DR may lead to irreversible visual impairment and blindness [1]. Evidence suggests that timely retinal screening and early treatment can substantially reduce vision-threatening complications and improve visual outcomes [2]. Despite advances in screening technology and treatment modalities, a significant proportion of diabetic individuals continue to present late due to inadequate awareness, poor health-seeking behavior, and limited access to ophthalmic services, particularly in rural settings [4]. Several studies have demonstrated that awareness regarding diabetic eye disease and retinal examination remains suboptimal in developing countries, contributing to delayed diagnosis and poor adherence to retinal screening recommendations [1,2].

Knowledge, attitude, and practice (KAP) studies provide valuable insights into community awareness, preventive beliefs, and healthcare utilization behavior related to chronic diseases and their complications [4]. Previous KAP studies conducted in India and other countries have reported substantial gaps between awareness and actual preventive practices related to diabetic retinopathy screening [2,3]. Although some individuals may possess basic knowledge regarding diabetes and its complications, this awareness often fails to translate into regular ophthalmic evaluation and retinal examination practices [3]. Studies from Saudi Arabia, South Africa, Nepal, and Nigeria have consistently demonstrated poor or moderate awareness regarding diabetic retinopathy, low uptake of retinal examination, and inadequate adherence to recommended eye care practices among diabetic patients [1,5,6,7]. Similar findings have also been reported from different regions of India, where poor diabetic retinopathy-specific awareness persists despite increasing general awareness regarding diabetes mellitus [8,9]. Most available KAP studies evaluate knowledge, attitudes, and practices using descriptive approaches or simple composite scoring systems. However, diabetic retinopathy screening behavior is multidimensional and influenced by several latent behavioral and healthcare utilization constructs that are often interrelated. Traditional descriptive analyses may not adequately identify the underlying domains influencing retinal screening uptake and preventive eye care behavior. Exploratory factor analysis offers an advanced statistical approach to identify hidden behavioral constructs by grouping correlated variables into meaningful latent domains [4]. Understanding these latent behavioral factors may provide deeper insight into the determinants of retinal screening behavior and help develop targeted educational and intervention strategies for rural populations.

Western Uttar Pradesh represents a region with a growing burden of diabetes, limited awareness regarding diabetic eye disease, and substantial rural healthcare disparities. Despite ongoing community-based screening initiatives and increasing ophthalmic outreach activities, the uptake of retinal screening services remains inconsistent. There is

limited evidence evaluating the latent behavioral dimensions underlying diabetic retinopathy screening behavior in rural North Indian populations. Therefore, the present study was undertaken to assess the knowledge, attitude, and practice related to diabetic retinopathy screening among rural adults in Western Uttar Pradesh using exploratory factor analysis. The study aims to identify the underlying behavioral domains influencing diabetic retinopathy screening uptake and healthcare-seeking behavior in this underserved population

METHODS

This community-based cross-sectional study was conducted among adults residing in rural areas of western Uttar Pradesh, India, to assess the latent behavioral domains influencing awareness and utilization of diabetic retinopathy screening services. The study was carried out using a structured interviewer-administered questionnaire developed to assess knowledge, attitude, and practice related to diabetes, hypertension, diabetic retinopathy, retinal examination, and eye-care seeking behaviour. Participants aged 40 years and above who were permanent residents of the selected rural communities and willing to participate were included in the study. Individuals who were unable to communicate effectively due to severe cognitive impairment, hearing impairment without a caregiver, or unwillingness to provide consent were excluded. Ethical approval for the study was obtained from the Institutional Ethics Committee prior to commencement of the study. The study adhered to the tenets of the Declaration of Helsinki. Written informed consent was obtained from all participants before enrollment. Participants were informed regarding the purpose of the study, voluntary nature of participation, confidentiality of responses, and their right to withdraw from the study at any stage without any effect on their healthcare services. No personal identifiers were included during statistical analysis, and collected data were securely stored with access restricted to the study investigators only.

A multistage community-based sampling approach was used for participant recruitment. Villages from the study area were selected based on accessibility and community outreach coverage areas. Households within the selected villages were approached consecutively, and one eligible participant from each household was enrolled after obtaining written informed consent. Interviews were conducted in the local language by trained independent interviewers who were not involved in clinical care delivery or retinal screening services to minimize interviewer bias and social desirability bias. All interviewers underwent prior training regarding administration of the questionnaire, uniform interpretation of responses, ethical conduct, confidentiality maintenance, and handling of participant queries. A pilot assessment was performed among a small subset of participants prior to initiation of the study to assess clarity and comprehensibility of the questionnaire, and necessary modifications were incorporated before final data collection. The minimum sample size for the study was calculated using the formula for single population proportion, $n = Z^2pq/d^2$, assuming a 95% confidence interval, absolute precision of 5%, and anticipated awareness of diabetic retinopathy of 35% based on previously published rural Indian studies. Using $Z = 1.96$, $p = 0.35$, $q = 0.65$, and $d = 0.05$, the calculated sample size was approximately 350 participants. Considering possible incomplete responses and missing data, a final sample size of 352 participants was included in the analysis. The sample size was also considered adequate for exploratory factor analysis, as recommendations suggest inclusion of at least 5–10 participants per variable. Since 19 variables were included in the factor analysis model, the available sample exceeded the minimum recommended participant-to-variable ratio and was considered statistically appropriate.

The questionnaire collected demographic information including age, gender, education, occupation, income, systemic illness, and duration of diabetes and hypertension. For exploratory factor analysis, variables were selected based on conceptual relevance to latent constructs related to knowledge, awareness, preventive attitude, and healthcare-seeking behaviour associated with diabetic retinopathy and retinal examination. Demographic and purely clinical variables such as age, gender, diagnosis, and visual acuity were not included in factor extraction because these variables do not represent latent behavioural constructs. Nineteen variables related to diabetes awareness, hypertension awareness, diabetic retinopathy awareness, retinal examination knowledge, preventive beliefs, and

healthcare utilization practices were selected for factor analysis after reviewing literature on diabetic retinopathy KAP studies and evaluating clinical relevance. All selected variables were converted into numeric codes before analysis. Binary variables were coded as "1" for correct or affirmative responses and "0" for incorrect, negative, or "don't know" responses. Variables such as knowledge of diabetes, awareness of diabetic retinopathy, awareness that diabetes affects eyes, awareness of retinal examination, importance of blood pressure control, and need for regular eye examination were coded dichotomously. Ordinal variables including frequency of blood sugar monitoring, timing of physician visits, and timing of eye doctor visits were coded in increasing order to reflect better healthcare-seeking behaviour and preventive practices. Responses such as "not applicable," refusal to answer, or missing information were treated as system-missing values during analysis.

Data were entered into Microsoft Excel and analyzed using IBM SPSS Statistics software version 21. Prior to factor analysis, data cleaning and validation procedures were performed to identify missing values, outliers, and coding inconsistencies. Descriptive statistics were generated for all variables. The suitability of the dataset for exploratory factor analysis was assessed using the Kaiser–Meyer–Olkin (KMO) measure of sampling adequacy and Bartlett's test of sphericity. Variables demonstrating inadequate communalities or poor correlation patterns were reviewed before final extraction. Internal consistency reliability of the selected variables was assessed using Cronbach's alpha coefficient. Exploratory factor analysis was performed using Principal Component Analysis extraction method with Varimax orthogonal rotation to identify underlying latent domains related to diabetic retinopathy awareness and healthcare-seeking behavior. Factors with eigenvalues greater than 1 were retained according to Kaiser's criterion, and the scree plot was examined to determine the optimal number of factors. Factor loadings greater than 0.40 were considered significant for interpretation. Variables loading strongly on similar components were grouped together and interpreted conceptually to derive meaningful behavioral domains such as diabetic retinopathy awareness, preventive attitude, and healthcare utilization behavior. Factor scores generated from the analysis were used for further interpretation and subgroup comparison where appropriate.

RESULTS

A total of 352 participants were included in the study. The mean age of the study population was 53.70 ± 10.03 years, with participants ranging from 29 to 80 years of age. Females constituted 53.7% (n=189) of the study population, while males accounted for 46.3% (n=163). Urban residents represented 60.8% (n=214) of participants, whereas 39.2% (n=138) belonged to rural areas. Hindu participants comprised 55.4% (n=195) of the study population, followed by Muslims at 44.3% (n=156). Most participants had no formal education (45.2%, n=159), while 16.5% (n=58) had intermediate-level education and 14.2% (n=50) had graduate-level education. Home duties were the most common occupation reported by participants (52.6%, n=185), followed by private employment (13.4%, n=47), unemployment (12.5%, n=44), and business occupation (11.9%, n=42). More than half of the participants (51.4%, n=181) reported a monthly family income between Rs. 10,001 and Rs. 20,000, while 35.5% (n=125) reported income between Rs. 2,001 and Rs. 50,000 (Table 1).

With respect to systemic illness, diabetes alone was reported by 41.2% (n=145) of participants, while 27.0% (n=95) had both hypertension and diabetes. Approximately one-fifth of participants (20.7%, n=73) reported no systemic illness. Spectacle use was present in 42.6% (n=150) of participants. Most participants (80.1%, n=282) reported no vision-related condition other than refractive error. Cataract was the most frequently reported ocular condition (9.4%, n=33), followed by diabetic retinopathy (3.4%, n=12). Regarding duration of diabetes, 31.0% (n=109) of participants were non-diabetic, while among diabetic individuals the most common duration was 1–5 years (23.3%, n=82), followed by less than one year (20.7%, n=73). Most participants (62.8%, n=221) were not hypertensive, whereas 11.4% (n=40) had hypertension for less than one year and 11.1% (n=39) had hypertension duration between 1 and 5 years (Table 2). Exploratory factor analysis was performed on 19 variables related to knowledge, attitude, and healthcare-seeking practices regarding diabetic retinopathy and retinal examination among rural adults. A total of 236 complete responses were included in the factor analysis. Principal Component Analysis with Varimax rotation and Kaiser

normalization was used for factor extraction. Six components with eigenvalues greater than 1 were retained, collectively explaining 61.47% of the total variance. The first component explained 21.52% of the variance, followed by the second (12.13%), third (9.09%), fourth (7.21%), fifth (6.22%), and sixth (5.29%) components. The scree plot demonstrated a gradual inflection after the sixth component, supporting retention of the six-factor solution.

Communality estimates ranged from 0.327 to 0.825, indicating adequate shared variance among most variables included in the model. Variables related to awareness of dilated retinal examination (0.825), knowledge regarding hypertension and diabetic complications (0.736–0.772), uptake of dilated retinal examination (0.785), and eye doctor visit history (0.686) demonstrated relatively high communalities, suggesting strong contribution to the extracted factors. After Varimax rotation, the extracted components demonstrated meaningful behavioral clustering. Component 1 predominantly represented "Retinal Examination and Eye Care Utilization Behavior," with strong loadings for awareness of dilated retinal examination (0.853), uptake of dilated retinal examination (0.823), and recent eye doctor visit (0.717). Component 2 represented "Hypertension-Related Awareness," with strong loadings for knowledge of hypertension (0.867), awareness that hypertension affects diabetic complications (0.831), and awareness that hypertension affects eyes (0.731). Component 3 represented "Preventive Diabetes Care Awareness," characterized by loadings for benefits of dilated retinal examination (0.742), appropriate eye examination frequency (0.540), diabetes hereditary awareness (0.570), and importance of blood pressure control (0.518). Component 4 reflected "Diabetic Eye Disease Awareness," with strong loadings for awareness that diabetes affects eyes (0.733), treatability of diabetes-related vision loss (0.625), and awareness of diabetic retinopathy (0.509). Component 5 was interpreted as "General Medical Care Utilization," based on strong loadings for recent physician visit (0.760) and prior diabetes testing (0.759). Component 6 represented "Need for Continued Ophthalmic Care," with high loading for the belief that ophthalmic consultation remains necessary despite blood sugar control (0.780), along with regular eye examination awareness (0.503) and importance of blood pressure control (0.534).

The rotated component matrix demonstrated satisfactory factor separation with most variables loading strongly onto a single factor, indicating good interpretability of the extracted domains. Variables associated with retinal screening uptake clustered distinctly from general awareness variables, suggesting that healthcare utilization behavior may represent a separate latent construct independent of general diabetic knowledge. These findings support the multidimensional nature of diabetic retinopathy screening behavior in rural populations. Table 3 summarizes the total variance explained by the extracted components, while Table 4 presents the rotated component matrix and interpretation of factor domains.

DISCUSSION

The present study explored the latent behavioral domains influencing diabetic retinopathy screening and eye care utilization among adults in Western Uttar Pradesh using exploratory factor analysis. The findings demonstrated that diabetic retinopathy screening behavior is multidimensional and influenced by several interrelated domains including retinal examination awareness, hypertension-related awareness, preventive health attitudes, diabetic eye disease awareness, healthcare utilization behavior, and perceived need for continued ophthalmic care. These findings provide important insight into the complex behavioral determinants underlying diabetic retinopathy screening uptake in underserved populations. The mean age of participants in the present study was 53.7 years, which is comparable to previous diabetic retinopathy awareness studies conducted in India and other developing countries where middle-aged and older adults constituted the majority of participants [10,11]. Females represented a slightly higher proportion of participants in our study, which may be attributed to the inclusion of a substantial number of homemakers and community-based recruitment. Similar gender distributions have been reported in previous KAP studies evaluating diabetic retinopathy awareness and diabetes-related healthcare utilization [10,12]. A considerable proportion of participants in the present study had no formal education, highlighting the persistent educational disparities in rural and semi-urban populations. Earlier studies have consistently shown that lower educational

status is associated with poor awareness regarding diabetic retinopathy and reduced uptake of preventive eye care services [10,13,14].

Diabetes alone and diabetes with hypertension were highly prevalent among study participants, emphasizing the growing burden of chronic non-communicable diseases in the region. Hypertension-related awareness emerged as one of the strongest latent behavioral domains in the factor analysis. This finding is clinically important because hypertension is a well-recognized risk factor for progression of diabetic retinopathy and other microvascular complications [15]. Participants who demonstrated awareness regarding hypertension and its ocular implications also appeared more likely to possess better preventive health attitudes. Similar associations between systemic disease awareness and healthcare-seeking behavior have been reported in studies from Saudi Arabia and South Africa [11,15].

One of the most important findings of the study was the emergence of a distinct "Retinal Examination and Eye Care Utilization Behavior" domain, characterized by strong loadings for awareness of dilated retinal examination, uptake of dilated examination, and recent eye doctor visits. This suggests that retinal screening behavior may represent a separate healthcare utilization construct independent of general diabetes awareness. Earlier studies have similarly reported that awareness regarding diabetes alone does not necessarily translate into regular retinal examination practices [10,16]. In many low-resource settings, patients may possess basic knowledge regarding diabetes while remaining unaware of the importance of periodic retinal evaluation [17]. The separation of healthcare utilization variables into a distinct factor in the present study supports the concept of an "awareness-practice gap" frequently described in diabetic retinopathy screening literature.

The factor labeled "Diabetic Eye Disease Awareness" demonstrated strong loadings for awareness that diabetes affects eyes, knowledge regarding treatability of vision loss, and awareness of diabetic retinopathy. Previous studies from India, Nepal, and Nigeria have similarly documented poor diabetic retinopathy-specific awareness despite moderate awareness regarding diabetes mellitus itself [10,14,17]. The relatively lower prevalence of diagnosed diabetic retinopathy in our study population may partly reflect under-screening and delayed detection rather than true disease absence. Lack of awareness regarding retinal complications remains a major barrier to early diagnosis and timely referral in rural populations [18]. The identification of a separate "Preventive Diabetes Care Awareness" factor indicates that preventive beliefs related to blood pressure control, regular eye examination, and benefits of retinal screening cluster together behaviorally. This finding has important implications for community-based educational interventions. Educational programs targeting preventive health behavior may improve both systemic disease management and retinal screening uptake simultaneously. Previous studies have demonstrated that physician counseling and patient education significantly influence adherence to diabetic eye care recommendations [11,18]. The factor structure observed in the present study further supports the need for integrated diabetes and eye health education strategies at the primary care level.

Another important finding was the emergence of a "General Medical Care Utilization" factor comprising physician visits and prior diabetes testing. This suggests that individuals already engaged with general healthcare services may be more likely to access diabetic retinopathy screening services. Similar observations have been reported in studies evaluating healthcare utilization patterns among diabetic populations [13,16]. Strengthening referral linkages between primary care physicians and ophthalmologists may therefore substantially improve retinal screening uptake. The present study differs from most previous KAP studies because it used exploratory factor analysis to identify latent behavioral domains rather than relying solely on descriptive awareness scores or composite indices. Traditional KAP studies often evaluate knowledge, attitude, and practice as independent domains, whereas factor analysis allows identification of underlying interrelationships among variables [10]. The six-factor structure identified in this study explained more than 60% of the total variance, indicating satisfactory representation of the behavioral constructs influencing diabetic retinopathy screening practices. The use of factor analysis therefore provides a more comprehensive understanding of retinal screening behavior in rural populations and may help guide development of targeted interventions.

The study has certain limitations. The cross-sectional design limits causal inference between behavioral domains and retinal screening uptake. Some responses were self-reported and may have been influenced by recall bias or social desirability bias. Additionally, factor analysis findings are dependent on the selected variables and study population, which may limit generalizability to other settings. However, the relatively large sample size, inclusion of both diabetic and non-diabetic adults, and use of standardized analytical methods strengthen the validity of the findings.

In conclusion, the present study identified multiple latent behavioral domains influencing diabetic retinopathy screening uptake among adults in Western Uttar Pradesh. Retinal screening behavior was found to be distinct from general diabetes awareness, emphasizing the presence of substantial awareness-practice gaps in diabetic eye care. Strengthening community awareness, physician counseling, preventive health education, and integration of retinal screening services within primary healthcare systems may improve uptake of diabetic retinopathy screening and reduce preventable visual impairment in underserved populations.

ABSTRACT

The past decade has seen a transformative period in the field of prosthetics, moving beyond simple mechanical replacements toward a new era of intelligent, bio-integrated, and user-centric devices. This review synthesizes key advancements in leg prosthetics from 2015 to 2026, providing a comprehensive overview of innovations in materials, control systems, surgical techniques, and their impact on patient outcomes. Break throughs in materials such as carbon fibre and titanium have enabled devices that are both lightweight and robust, significantly improving biomechanical efficiency and reducing the metabolic cost of walking. The introduction of intelligent systems, including microprocessor-controlled knees and ankles, has led to demonstrably improved safety and mobility, particularly for high-risk populations. Surgical procedures such as targeted muscle reinnervation and osseointegration have addressed long-standing challenges of socket-related discomfort and pain, while simultaneously

providing a more intuitive and stable interface for device control. A critical analysis of the literature reveals that restoring sensory feedback is a crucial, non-negotiable component for achieving true psychological and neurological integration of the prosthesis. While these technological and surgical innovations have yielded significant improvements in functional mobility, patient satisfaction, and quality of life, the field continues to grapple with persistent challenges. A considerable gap remains between the priorities of technology developers and the core, day-to-day needs of users, leading to high rates of prosthetic abandonment. Furthermore, systemic barriers of high cost and limited insurance coverage create a significant access disparity, raising profound ethical questions about technological discrimination. The path forward necessitates a concerted effort to not only advance technology but also to bridge the gap between research and clinical practice, prioritize user-centred design principles, and develop equitable policies to ensure that all individuals with limb loss can benefit from these life-changing advancements

Keywords: mobility,

INTRODUCTION

As per the WHO standards for prosthetics and orthotics**,** WHO estimates that, today, only 1 in 10 people in need has access to assistive products, including prostheses and orthoses, because of their high cost and because of lack of awareness, availability, trained personnel, policy and financing. Hence, WHO is coordinating a global initiative, "Global cooperation on assistive technology" (GATE), to improve access to high-quality, affordable assistive products[1].

The Context of Limb Loss

Limb loss represents a profound and life-altering event that impacts an individual's physical, psychological, social, and economic well-being[2]. The loss of a limb necessitates a complex journey of physical rehabilitation, psychological adaptation, and reintegration into daily life. For centuries, the primary goal of prosthetic science has been to create artificial limbs that can restore function and mobility. Despite these efforts, the development of a device that can truly replicate the function of a biological extremity is far from complete[3] . This persistent challenge is reflected in the historically high rates of prosthetic rejection and abandonment, with studies reporting rejection rates as high as 23% in adults and 35% in children using electrically powered prosthetics[4].A lack of comfort, poor functionality, and the absence of sensory feedback have been consistently cited as the leading causes of this rejection[2]. These issues underscore the fact that a prosthetic device must be more than a simple tool; it must be a seamlessly integrated extension of the user's body.

Purpose of this Review

The purpose of this report is to provide a comprehensive, expert-level review of the latest advancements in leg prosthetics that have emerged over the last decade, spanning from 2015 to 2025. The aim is to synthesize the myriad of breakthroughs in materials science, intelligent control systems, and surgical techniques, and to critically assess their collective impact on patient outcomes, satisfaction, and overall quality of life. The report goes beyond merely enumerating innovations by exploring the complex interdependencies between these advancements and their real-world implications for prosthetic users. It examines how improvements in one area, such as surgical integration, can unlock the full potential of another, such as advanced control systems. Additionally, this review will shed light on the persistent challenges that continue to impede widespread adoption and equitable access to these technologies, including issues of cost, policy, and the critical need to close the gap between technological development and clinical implementation.

Scope and Structure

This review is structured to first address the foundational technological and material innovations that have defined the modern era of prosthetic design. It will then delve into the sophisticated intelligent systems and surgical bio-interfacing techniques that are revolutionizing mobility and control. A dedicated section will explore the critical and often overlooked role of sensory feedback in achieving true mind-body integration. The report will then pivot to a holistic assessment of clinical outcomes and patient-reported satisfaction, using standardized metrics to provide a quantitative and qualitative understanding of the impact of these technologies. Finally, a critical discussion of the remaining challenges and future directions will identify key areas for future research and policy action.

Foundational Advancements in Prosthetic Design and Materials

The Evolution of Materials

The evolution of prosthetic limbs is a testament to the advancements in materials science. Historically, prosthetic devices were crafted from simple, cumbersome materials like wood and early metals, which severely limited both function and comfort[5]. In the past decade, a profound shift has occurred toward advanced, performance-based materials that are meticulously selected for specific functions within the device. The most prominent example of this is the widespread adoption of **carbon fiber**[5]. This advanced composite material is prized for its exceptional strength-to-weight ratio, high stiffness, and remarkable ability to store and release energy[6]. These properties enable a more energy-efficient and natural gait, reducing the metabolic cost for the user and enabling highly active individuals to achieve peak speeds that nearly match those of non-amputees[6]. For internal, load-bearing components, **titanium** has become the gold standard[5]. Its superior strength, low weight, and resistance to corrosion make it ideal for parts that demand high durability[7].A key biomechanical advantage of titanium is its low modulus of elasticity, a characteristic that makes it like bone. This property ensures a more even distribution of skeletal load between the implant and the bone, contributing to a more comfortable and natural walking experience[7].

While high-performance materials address the biomechanical needs of a prosthetic, advancements in polymers and elastomers address the crucial elements of comfort and aesthetics. Silicone and polyurethane, for instance, are widely used for socket liners and cosmetic covers due to their flexibility, skin-like texture, and biocompatibility[5]. These materials reduce friction, prevent skin irritation, and allow for a more natural feel, which is essential for user comfort and long-term acceptance[8]. The focus on these materials represents a design philosophy that recognizes that a prosthetic device must not only function well but also feel and look like a natural part of the body to promote embodiment and self-identification[9]. The trend in materials development is a dual-focused approach that simultaneously pursues high-performance biomechanical function and a human-centric design philosophy. Materials like carbon fiber and titanium are selected based on their engineering properties (e.g., strength-to-weight ratio, durability), which directly impact functional metrics such as gait efficiency and energy expenditure. Concurrently, materials like silicone and thermoplastics are prioritized for their aesthetic and comfort-related properties, such as flexibility, skin-like texture, and breathability. This is not a contradiction but a sophisticated synthesis of priorities. The field has matured beyond simply replacing a limb's function; it now understands that factors like comfort and aesthetics are equally critical to user satisfaction, acceptance, and long-term use. A highly advanced, multi-functional device is of limited utility if the patient abandons it due to persistent discomfort or a feeling of being disconnected from the device. Therefore, a successful prosthetic device in the modern era must be both a high-performance biomechanical tool and a comfortable, aesthetically pleasing extension of the body. The following table summarizes the key properties and applications of these advanced materials in prosthetic design.

The Rise of Digital Manufacturing and Customization

The advent of digital manufacturing has profoundly influenced prosthetic design and fabrication. 3D printing (additive manufacturing) has emerged as a potentially viable alternative to traditional fabrication methods, particularly for producing prosthetic sockets[5]. This technology offers several compelling benefits, including cost-effectiveness, the ability to create highly customized geometries for each user, and rapid prototyping.[14] By significantly reducing the cost of materials and fabrication time, 3D printing presents a compelling solution for

increasing access to prosthetic care, especially in settings where cost or resources are limited[10]. However, the technology is not without its challenges. The sources temper the promise of 3D printing with a realistic assessment of its current limitations. The structural integrity of 3D-printed sockets under high loads remains a significant concern, although this can be improved by the addition of composite materials like carbon fiber particles[10]. A crucial point is that 3D printing is not a "ready-to-use solution" that can simply be deployed without expert oversight[11]. The public perception of the technology, often shaped by media, is disconnected from the clinical reality where expert knowledge is still essential for ensuring proper fit and function[11].

This situation highlights that 3D printing technology is a democratizing force for manufacturing but not a complete panacea for all challenges. While the technology can revolutionize accessibility and prototyping by lowering costs and streamlining fabrication, its full potential is realized when it is integrated as a tool for clinicians, not as a replacement for their expertise[11]. The true innovation lies in using digital methods to augment the prosthetist's ability to create a custom, evidence-based device.

Computer-Aided Design and Manufacturing (CAD/CAM) systems, for example, have been shown to save time and lead to comparable or better clinical outcomes, ultimately improving the patient's quality of life[12]. These systems also create a perpetual, quantitative design record, which is invaluable for education, peer support, and future modifications[12]. This demonstrates that the digital approach complements, rather than replaces, the human element, allowing prosthetics' to focus on the more highly skilled aspects of customization and patient interaction[12].

Intelligent Systems and Enhanced Mobility

Microprocessor-Controlled Joints (MPKs and MPAs)

A major shift in prosthetic technology has been the integration of intelligent, sensor-driven systems, particularly in prosthetic knees and ankles. Microprocessor-controlled knees (MPKs) have emerged as a definitive advancement over their passive, mechanical counterparts. MPKs utilize sophisticated sensors and hydraulic systems to respond to real-time gait changes, providing enhanced stability, stumble recovery, and a more physiological gait pattern[13]. This continuous, adaptive control is a key differentiator from non-microprocessor knees (NMPKs), which face an inherent conflict between providing stability for weight-bearing and allowing for dynamic function during walking[14]. The most compelling evidence for the efficacy of MPKs comes from the landmark ASCENT K2 clinical trial. This 12-month, prospective, randomized controlled trial specifically examined the impact of MPKs on the K2 patient population, which includes older adults with limited mobility who have a high risk of falling. The results provided a strong evidence-based justification for MPK use in this group. At the conclusion of the trial, individuals using MPKs experienced a significant reduction in falls and near-falls, reporting approximately one fall compared to three falls for the NMPK group[13].This demonstrates a 66% reduction in fall-related events. Furthermore, the MPK group maintained their health-related quality of life (HR-QoL), while the NMPK group experienced a significant decline[13].

This quantitative data shows that microprocessor technology is not merely a luxury for high-performance users but a critical, evidence-based tool for safety and independence, particularly for vulnerable populations. The ASCENT K2 trial fundamentally shifts the narrative by providing irrefutable evidence of a direct cause-and-effect relationship: providing MPK technology (cause) leads to fewer fall events and reduced fear of falling (effect)[13]. This data is crucial for justifying the higher cost of these devices and supports policy changes for expanded insurance coverage, recognizing MPKs as a medically necessary technology for this high-risk population. Similarly, microprocessor-controlled ankles (MPAs) and feet have been developed to enhance gait and stability. Devices like the Proprio Foot and Elan Foot combine intelligent bionic ankle motion with the energy-returning dynamics of carbon fiber feet[15].These devices automatically adjust to changing terrains, inclines, and even varying heel heights, actively increasing toe clearance during the swing phase of gait to reduce the risk of trips and falls[15].

Powered Prostheses

While microprocessor-controlled joints have demonstrated significant success, the field is also advancing the development of fully powered prostheses. These devices are designed to actively assist movement by generating power to support the patient's weight and propel them forward, a major advancement over passive devices that simply store and release energy[2]. This can lead to a significant reduction in the metabolic cost of walking, allowing users to move more efficiently and for longer periods[16].Despite their potential, powered knees and ankles still face considerable challenges, including excessive weight, bulkiness, and inefficiency, which have limited their commercialization and widespread adoption[2].

Intuitive Control and Signal Processing

The effectiveness of intelligent prosthetics is directly tied to the sophistication of their control mechanisms. The development of myoelectric control, which uses the electrical signals from residual muscles, has been a cornerstone of this progress[4]. A significant evolution has been the shift from simple on/off control, based on the activation of a single muscle, to advanced Pattern recognition technology, This innovation allows a user to correlate a specific electromyography (EMG) signal pattern from several synergistic muscles with a pre-programmed action, enabling simultaneous control of multiple degrees of freedom[3]. This advancement directly addresses the frustration and high abandonment rates associated with "mode switching" in earlier devices, making the control of the prosthesis more intuitive and adaptable[2].

The advancement of control systems is a fundamental quest for intuitive, biomimetic integration. The sources show a clear trend away from requiring the user to adapt to the device's limitations and toward the device adapting to the user's intent. This is best exemplified by the progression from simple, single-muscle myoelectric control to complex pattern recognition technology[3]. The core problem being solved is the cognitive load and frustration caused by the need for "mode switching" or sequential control. By allowing for simultaneous, multi-degree-of-freedom control, pattern recognition creates a more seamless, natural, and intuitive experience[2]. This directly addresses the high abandonment rates tied to unintuitive control mechanisms and represents a core design philosophy of "biomimicry," where the artificial limb mimics the dynamic, adaptive qualities of natural muscle actuation[15].

Surgical Integration and Bio-Interfacing

Targeted Muscle Reinnervation (TMR)

For decades, the interface between the human body and a prosthetic device was a major source of pain and discomfort, often leading to device rejection[2].Recent surgical advancements have begun to bridge this gap, fundamentally altering the relationship between the body and the prosthesis. One such groundbreaking procedure is Targeted Muscle Reinnervation (TMR), a surgical technique that involves rerouting nerves from the amputated limb to nearby, intact muscles that have lost their original function[3]. This procedure offers a dual benefit. First, it provides a physiological "end organ" for the nerves to innervate, which prevents the chaotic, misdirected growth that leads to the formation of painful neuromas[17].Clinical studies have shown TMR to be remarkably effective in reducing or eliminating residual limb and phantom limb pain[17]. For example, a prospective study of 33 amputees showed that TMR significantly reduced numerical rating scale (NRS) scores for residual limb pain from 6.4±2.6 to 3.6±2.2 and phantom limb pain from 6.0±3.1 to 3.6±2.9 one year after surgery[18]. Second, by providing these new muscle targets, TMR effectively creates "biological amplifiers" for the nerve signals. When a user thinks about moving their missing limb, the signal is amplified by the new target muscle, producing a robust EMG signal that can be captured by sensors and used to intuitively control a myoelectric prosthetic[19].

Osseo Integration (OI)

Another transformative surgical procedure is **osseo integration**, which allows for the direct skeletal attachment of a prosthesis, eliminating the need for an external socket[3]. The socket has long been a source of significant complications, including perspiration, skin ulcers, and irritation[20].OI solves these problems by creating a direct, stable connection between the prosthesis and the residual bone.

The clinical outcomes for OI have been promising. A Swedish study on the OPRA™ Implant System reported a 92% success rate at five years, with benefits sustained for up to 15 years post-operation[20]. Patients who have switched from a socket prosthesis to an Osseo integrated one have shown superior functional mobility outcomes[20]. Objective tests demonstrate this improvement: patients can walk approximately 25% farther on the 6-Minute Walk Test and complete the Timed Up and Go (TUG) test nearly 20% faster than their socket-using counterparts, achieving test times comparable to non-amputated individuals[21]. A key benefit of OI is the improved sense of proprioception, known as "osseoperception," where mechanical stimulation of the implant provides a passive awareness of the limb's position and function[20].

The future of prosthetics is a symbiotic human-machine interface, where surgical intervention is a prerequisite for optimal function. The sources demonstrate that TMR and OI are not isolated advancements but foundational, synergistic surgical procedures. OI addresses the long-standing "socket problem" by eliminating socket-related complications and providing a stable physical connection. TMR, in turn, addresses the "control problem" by providing intuitive motor control and alleviating chronic pain, a major contributor to prosthetic abandonment. When these two procedures are combined, as in ongoing studies, OI provides a stable platform for EMG sensors while TMR enhances the quality of the signals, leading to improved pattern recognition and prosthetic control[22]. This synergistic relationship moves the field from simple device attachment to true bio-integration. Furthermore, these surgical advancements indicate a shift in the role of amputation itself. Rather than being the reactive endpoint of a traumatic event or disease, the amputation procedure can now be the first step in a proactive, planned, long-term rehabilitation process[5]. TMR can be performed as a "primary" procedure at the time of amputation to prevent painful neuromas and optimize a patient for future prosthetic use[23]. This forward-thinking clinical approach recognizes that a strong surgical foundation is essential for long-term patient outcomes and prepares the patient for the full benefits of advanced prosthetic technology. The following table synthesizes the benefits of these two key surgical advancements

The Critical Role of Sensory Feedback

The Need for Sensation

A persistent challenge in prosthetic design has been the inability to restore sensory feedback. The lack of sensation has been cited as a primary cause of high prosthetic rejection rates, as it forces users to rely on their other senses, primarily vision, to operate the device[2]. This constant reliance on visual and auditory cues is mentally and physically taxing, leading to heightened mental and physical fatigue, reduced confidence, and slower walking speeds[3]. The absence of feedback can also intensify the sensation of phantom limb pain, a common and debilitating condition for many amputees[24]. Achieving a high-functioning prosthetic system requires a closed feedback loop that provides the brain with continuous information about the device's position, grip force, and interaction with the environment[25].Without this feedback, the user's perception of the prosthesis as an extension of their body is severely limited, hindering the sense of ownership and embodiment that is critical for long-term use and psychological well-being[24].

Advancements in Sensory Restoration

Recent research has focused on developing methods to restore this missing sensation. These advancements can be broadly categorized as invasive and non-invasive.

Invasive methods involve the use of implanted sensors within muscles or nerves to directly provide feedback to the nervous system[4]. Intraneural stimulation, for example, has been used to provide a variety of sensory perceptions, from object stiffness and size to tactile sensations[4].A study on leg prosthetics with intraneural stimulation demonstrated a significant reduction in mental effort, an increase in walking speed, and elevated confidence levels in participants[24].

Non-invasive methods involve providing feedback through the skin of the residual limb. Haptic devices and vibration alerts, for instance, have been used to provide real-time tactile information about the prosthetic's position or the force it is exerting on an object[3]. These non-invasive techniques have shown promising results in improving prosthesis performance and the user's sense of embodiment, without the need for surgery[4]. Sensory feedback is the essential "missing link" for bridging the mind-body gap in prosthetics. While advancements in motor control systems and surgical interfaces provide a powerful physical connection, the data on sensory feedback reveals a critical psychological and neurological component. The high rejection rate for advanced prostheses is not solely a problem of function but a problem of a "closed loop" system. The brain requires continuous feedback to achieve a sense of ownership and control over the device.[4] The study on leg prosthetics with intraneural stimulation provides a direct causal relationship: the presence of sensory feedback (cause) leads to a reduction in mental effort and an increase in walking speed and confidence (effect)[24].This demonstrates that sensation is not an optional feature but a foundational requirement for achieving true psychological and neurological integration.Beyond its role in embodiment and control, restoring sensation has significant downstream health and quality-of-life benefits. The sources indicate that providing sensory feedback has been shown to reduce phantom limb pain and decrease mental and physical fatigue[24]. Reduced metabolic cost and improved walking economy have been linked to a counter to the long-term cardiovascular risks associated with above-knee amputations[24]. This is a profound finding: an advancement in a seemingly small area like sensation can have a ripple effect on major health outcomes, reinforcing the idea that a holistic approach to prosthetic design yields broader benefits for the user's long-term health and well-being.

Clinical Outcomes, Patient Satisfaction, and Quality of Life

Objective Functional Outcomes

Objective, performance-based outcome measures are essential for quantifying the benefits of advanced prosthetic technologies. The Timed Up and Go (TUG) test, which assesses basic mobility and falls risk, and the 6-Minute Walk Test (6MWT), which measures endurance and walking distance, are two such widely used metrics[21].

Clinical data shows that advanced prosthetics lead to significant improvements in these measures. For example, individuals using osseointegrated prostheses completed the TUG test nearly 20% faster than those with traditional sockets and were able to walk approximately 25% farther on the 6MWT[21]. This data, combined with findings that advanced prosthetics can nearly match non-amputees in peak speed, demonstrates that these technologies are not just incrementally better but fundamentally transformative for functional mobility[6].

Patient-Reported Experiences

While objective measures are important, patient-reported experiences are equally crucial for understanding the real-world impact of a prosthetic. Surveys such as the Prosthetic Limb Users Survey of Mobility (PLUS-M™) and the Socket Comfort Score (SCS) provide valuable insights into a user's perceived ability to perform activities and their satisfaction with the device[26]. A critical finding from these surveys is the dissonance between the priorities of developers and the core needs of users. While developers focus on complex, high-tech, and often invasive functionalities, patient-reported data consistently identifies comfort, durability, and safety as the most important factors for satisfaction[2]. Paradoxically, these are also the areas with the highest rates of dissatisfaction, particularly concerning durability, repairs, and technical assistance.[36] A significant portion of upper-limb prosthetic users, for instance, rejected their device despite being prescribed one of the most advanced technologies available[2].This is because a large number of users prefer non-invasive devices and the ability to perform basic daily functions over undergoing surgery for advanced capabilities they may not need or use[2]. This is a critical observation for the future of research and development: the focus must shift from a "technology-first" to a "user-centric" approach, ensuring that solutions address the fundamental, day-to-day needs of the majority of amputees, which could help combat the high abandonment rates[2].

Quality of Life (QoL) and Psychosocial Well-being

The ultimate measure of a prosthetic's success lies in its ability to improve a user's overall quality of life. Access to and the ability to use a prosthesis are identified as important predictors of QoL, as they allow for improved mobility and, in turn, increased independence[27].Advanced prosthetics have been shown to enhance social integration, self-esteem, and psychological well-being.[3] The ability to regain employment and live independently provides significant economic and societal benefits, including a reduction in long-term healthcare costs and a lessened reliance on welfare and disability benefits[28]. The value proposition of advanced prosthetics extends far beyond the individual, creating a broader societal benefit. The data provides a strong economic and social justification for investing in advanced prosthetics and rehabilitation services. Improved prosthetic function and a better quality of life are not isolated benefits; they lead to increased independence, successful return to meaningful community participation, and the regaining of employment[28]. This, in turn, reduces long-term healthcare costs and lessens the burden on welfare and disability benefits[28]. An economic analysis found that every dollar spent on rehabilitation saves the economy 11 dollars in various benefits[29].This demonstrates that the benefits of advanced prosthetics are not just a matter of personal health but a sound public investment with significant downstream societal and economic returns.

Challenges and Future Directions

The Research-to-Clinic Gap

Despite the rapid pace of innovation, a persistent gap remains between the development of new technologies and their successful implementation in clinical practice[2].Developers and manufacturers are sometimes disconnected from the practical needs of clinicians and people with limb loss[11].This can lead to the creation of devices that, while technologically impressive, are not practical or intuitive for everyday use[2].Furthermore, a lack of clear instructions and training materials can impede patient adaptation, contributing to frustration and device rejection[2].

Barriers to Access

The high cost of advanced prosthetics is arguably the single greatest barrier to access. A lower extremity prosthetic can range in cost from $5,000 to $50,000, and the total lifetime cost of care can exceed $345,000, a figure well beyond the financial capabilities of most individuals[29]. While insurance providers and government programs like Medicare typically cover the majority of these costs, significant limitations and out-of-pocket expenses remain[30].The absence of comprehensive health economic evaluations for many of these advanced devices creates an evidence gap that complicates policy and investment decisions, preventing the widespread adoption of life-changing technologies[31].

Ethical Considerations

As technology becomes more sophisticated, a number of ethical considerations come to the forefront.

- **Balancing Innovation and Accessibility:** A primary ethical dilemma is the balance between creating groundbreaking, high-cost technologies and ensuring that they are accessible to all individuals, regardless of their socioeconomic status[32].This raises questions about a potential technological divide between those who can afford advanced devices and those who cannot[6].
- **Data Security and Privacy:** The integration of smart technologies in modern prosthetics that collect and transmit data raises serious concerns about data security and privacy. Ethical questions arise regarding who has access to this sensitive health information and how it may be used[32].
- **Technological Discrimination and Identity:** The potential for a divide between those with and without access to advanced technology could lead to technological discrimination[32]. Furthermore, the development of devices that closely approach or even exceed biological function introduces a philosophical debate about the distinction between "therapy" and "enhancement," and how these devices may fundamentally alter an individual's psychological and bodily identity[33].

Outlook and Future Directions

The future of leg prosthetics is characterized by a continued push toward greater intelligence, integration, and accessibility. The integration of artificial intelligence (AI) and machine learning is anticipated to further enhance the adaptivity and responsiveness of prosthetics, allowing for more seamless and intuitive control.[8] The field must embrace a more formal and structured approach touser-centred design, involving amputees and clinicians in the design process from the outset to ensure that new technologies address real-world needs like comfort, durability, and practical function[2].Finally, bridging the access gap will require a concerted effort from policymakers, researchers, and manufacturers to develop cost-effective solutions and create policies that ensure equitable access to life-changing care[31].The need for larger, longer-term studies is also paramount to solidify the findings on durability, long-term outcomes, and the psychological and social impacts of advanced devices[9].

CONCLUSION

The last decade has witnessed a profound paradigm shift in prosthetic technology, marked by a departure from purely mechanical devices toward sophisticated, bio-integrated, and intelligent systems. The confluence of surgical innovation, such as TMR and osseointegration, with advancements in intelligent control and advanced materials has yielded devices that significantly improve functional mobility, safety, and overall quality of life. The clinical evidence is clear: these technologies are no longer speculative but are demonstrably effective in reducing falls, improving gait, and enhancing patient well-being. The review of current technologies also reveals limitations in socket adjustability and user-specific adaptability. Conventional prosthetic sockets often do not account for residual limb volume changes, leading to discomfort and reduced usability. Adjustable systems and hybrid designs that combine flexible and rigid components were recommended in several studies to address these issues effectively. Notably, previous literature calls for greater emphasis on user-centric, sustainable design approaches to accommodate the physical and economic diversity among prosthesis users.By focusing on these challenges, the field can move closer to its goal: not just to replace a missing limb, but to empower individuals with the freedom, confidence, and independence to live their lives to the fullest.

Table 1: Key Properties and Applications of Advanced Prosthetic Materials

Material	Key Properties	Primary Application
Carbon Fiber	High stiffness, high tensile strength, low weight, energy storage & return	Feet, structural components
Titanium	Superior strength, low weight, corrosion resistance, biocompatible, low modulus of elasticity	Internal, load-bearing components
Silicone	Flexibility, skin-like texture, biocompatibility, non-toxic, durability	Socket liners, covers, customizable prosthetics, pneumatic/hydraulic systems
Polypropylene	Lightweight, flexibility, good tensile strength, hardness, rigidity, ease of molding	Sockets, orthoses, rigid structures
Polyurethane	Flexible, adaptable, foam properties, strong, durable	Foam for feet, liners, insulation

Table 2: Comparative Clinical Outcomes of Microprocessor Knees

Outcome Measure	Microprocessor Knee (MPK) Group	Non-Microprocessor Knee (NMPK) Group	Significance	Source
Falls (12-Month Period)	~1 fall	~3 falls	Significant reduction in fall events for MPK group	[13]
Near-Falls (12-Month Period)	~2 near-falls	~6 near-falls	Significant reduction in near-fall events for MPK group	[13]
Timed Up and Go (TUG) Test	~10 seconds faster	Baseline	Significant improvement in TUG scores for MPK group	[13]
Health-Related Quality of Life (HR-QoL)	Maintained QoL	Significant decline in QoL	Significantly favourable results for MPK group	[13]
Fear of Falling (FFABQ)	Significantly decreased (improved) score	No significant change	Significant improvement in fear-of-falling behaviors for MPK group	[13]

Table 3: The Multifaceted Benefits of Surgical and Bio-Integrated Interfaces

Interface Type	Primary Benefits	Key Clinical Outcomes	Source
Targeted Muscle Reinnervation (TMR)	Intuitive prosthetic control, pain reduction (phantom and residual limb pain), prevention of neuromas	Significantly reduced NRS pain scores for phantom (6.0→3.6) and residual limb pain (6.4→3.6)	[17]
Osseointegration (OI)	Elimination of socket-related issues, improved proprioception, increased range of motion, improved gait, greater comfort while sitting	Improved gait (25% farther on 6MWT), faster TUG test completion (~20% faster), and a 92% success rate at 5 years	[21]

ABSTRACT

Sleep deprivation among university students represents a growing public health concern associated with impaired neurocognitive functioning, heightened fatigue, and diminished academic performance. Inspiratory Muscle Training has demonstrated benefits across respiratory and sleep-related disorders, yet its application as a non-pharmacological intervention in sleep-deprived young adults remains underexplored. An experimental clinical trial was conducted. From 123 initially screened participants, 65 met inclusion criteria (PSQI > 5; FSS ≥ 36) and participated in a structured conch blowing and breathing exercise protocol over four weeks. Fifty participants completed the intervention and were assessed pre- and post-intervention using the Wilcoxon Signed-Rank Test and Paired t-testat $\alpha = 0.05$. All outcomes demonstrated statistically significant improvement ($p < 0.001$) with large effect sizes. PSQI scores declined from 7.30 ± 2.49 to 3.66 ± 1.53 (Cohen's d = 2.76); FSS from 43.44 ± 6.17 to 29.64 ± 4.58 (d = 3.57); TMT-A completion time from 36.35 to 26.28 seconds (d = 1.66); and TMT-B from 67.15 to 42.21 seconds (d = 0.81). Conch blowing-induced IMT significantly improves sleep quality, reduces fatigue severity, and enhances neurocognitive performance in sleep-deprived young adults.

.

Keywords: Conch blowing; Inspiratory Muscle Training; sleep quality; fatigue; neurocognition

INTRODUCTION

Sleep is a fundamental physiological and psychological state characterised by altered consciousness, reduced sensory activity, and near-complete cessation of voluntary movement. Adequate sleep is indispensable for brain function, memory consolidation, emotional regulation, and physical restoration. Adults aged 18–60 years are recommended to obtain a minimum of seven hours of sleep per night; yet sleep deprivation is increasingly prevalent, particularly among university students who confront mounting academic pressures, irregular schedules, excessive digital screen exposure, and suboptimal sleep hygiene. Sleep deprivation in young adults is not merely a lifestyle inconvenience — it carries well-documented consequences for neurocognitive performance, including diminished attention, impaired working memory, slowed processing speed, and compromised executive function. Fatigue secondary to chronic sleep insufficiency further undermines academic productivity, social functioning, and mental well-being. Epidemiological estimates suggest that between 10% and 50% of university students experience clinically significant sleep disturbance at any given time. Sleep is necessary for overall well-being, emotional regulation, and cognitive performance. Many students suffer from chronic sleep loss caused by social commitments, technological distractions, and academic pressure. Their mental health suffers significantly as a result of the lack of sleep, with symptoms including increased stress, anxiety, sadness, and cognitive deterioration [1].

University students facing higher levels of academic and employment stress were more prone to experiencing poor sleep quality. Academic pressures coupled with job-related concerns can lead to heightened worries about the future. Such stress generates considerable psychological strain, which can directly interfere with the ability to obtain restful sleep. The anticipation of future events and obligations often keeps the mind actively engaged at night, preventing the relaxation necessary to initiate sleep. Environmental elements in a university setting can also be disruptive to sleep. The sleeping habits of roommates, noisy dormitory environments, and poor dormitory hygiene can hinder university students from attaining a conducive sleeping environment, resulting in compromised sleep quality [2]. Conventional interventions for sleep disturbance in students include cognitive behavioural therapy for insomnia (CBT-I), sleep hygiene education, and pharmacological agents. However, these approaches are either resource-intensive, inaccessible, or associated with adverse effects. There is a recognised gap in the availability of low-cost, physiologically grounded, non-pharmacological interventions that can be self-administered within a student population.

Inspiratory Muscle Training (IMT) — the structured exercise of muscles involved in inhalation — has demonstrated efficacy in improving oxygenation, cardiovascular efficiency, autonomic regulation, and perceived fatigue across diverse clinical populations, including individuals with obstructive sleep apnoea (OSA) and chronic fatigue-related conditions. It may reduce airway collapsibility and sympathetic output, which may decrease OSA severity and blood pressure [3]. Emerging evidence indicates that IMT may positively modulate autonomic nervous system activity, enhancing parasympathetic tone and thereby promoting sleep onset and continuity. However, recently conducted investigations yields controversial findings with studies depicting significant improvement in inspiratory muscle strength (IMS), sleep quality, lung function, and apnea-hypopnoea index (AHI), while other studies depicted no significant change in lung function, AHI and exercise capacity following IMT [4]. Inspiratory muscle training can be performed systematically using devices that provide quantifiable resistance targets and instant performance feedback. These targets are usually set as a percentage of the maximum inspiratory pressure that an individual can generate, as measured by a sensor in the device. The technique is akin to weight training where a set of repetitions is performed using a fixed weight. As the respiratory muscles gain strength, the IMT device allows the target resistance to be increased, so the training adapts to the person's current strength [5]. Home-based Threshold inspiratory muscle training (TIMT) program in OSA severity, daytime sleepiness, and pulmonary function in newly diagnosed OSA can be simple efficacious, and cost-effective [6].

Shankh (conch shell) blowing, a yogic breathing exercise involving forceful exhalation through a conch shell, has been considered to strengthen the oropharyngeal and respiratory muscles and improve lung function. This spiral-shelled device has been used as a musical instrument or decorative piece for centuries. Many authors have observed a subjective improvement in daytime sleepiness among individuals with OSA who were engaged in the practice of shankh blowing. The shankh, specifically, Turbinella pyrum or the "Indian Shankha", possesses a unique spiralling structure with an inner cavity growing both axially and transversely. When blown, it produces a resonating sound field believed to hold healing properties.[7] Conch blowing is also known as Shankha Naad in the Indian cultural tradition, is an indigenous practice requiring forceful deep inhalation followed by prolonged exhalation through a conch shell — a biomechanical process that constitutes a natural and culturally familiar form of IMT. The practice promotes slow rhythmic breathing, increases respiratory muscle endurance, and may activate vagal pathways conducive to relaxation and improved sleep architecture. Given its simplicity, negligible cost, widespread cultural acceptance particularly in South Asian populations, and absence of known contraindications in healthy individuals, conch blowing merits systematic scientific evaluation. This study aimed to evaluate the effectiveness of a structured conch blowing-induced IMT protocol on sleep quality, fatigue severity, cognitive processing speed, and executive function among sleep-deprived university students over a four-week intervention period.

MATERIALS AND METHODS

Study Design

A two-phase experimental clinical trial design was employed. Phase I constituted a cross-sequential study development design for protocol development and expert content validation. Phase II was an experimental pre-post study examining the effectiveness of the validated protocol on sleep, fatigue, and neurocognition in sleep-deprived university students. The study was approved by the Institutional Ethics Committee of Brainware University (Ethics Approval No: BWU/AHS/NOC/DSC/2026/020) and carried out in accordance with the Declaration of Helsinki. Written informed consent was obtained from all participants. The CONSORT 2010 guidelines were followed in reporting this trial (Figure 1).

Participants

University students aged 18–25 years enrolled at Brainware University, Barasat, Kolkata, West Bengal, India were recruited via convenience sampling. Inclusion criteria required a PSQI score greater than 5 (indicative of poor sleep quality) and an FSS score of 36 or above (indicative of severe fatigue). Participants were excluded if they had a history of respiratory, cardiovascular, or neurological disorders; were using medications known to affect sleep or respiratory function; were engaged in concurrent breathing training programmes; or smoked or used substances potentially affecting respiratory performance.

Of 123 students initially assessed, 65 met the inclusion criteria. Following baseline assessment, 15 participants were excluded for irregular attendance, yielding a final analytic sample of 50 participants who completed the four-week intervention.

Protocol Development and Validation (Phase I)

A structured Shankha-based IMT protocol was systematically developed incorporating graded intensity (30% to 60% perceived inspiratory effort across four weeks), frequency (twice daily), supplementary breathing exercises (diaphragmatic breathing, pursed-lip breathing, thoracic expansion, segmental breathing, and inspiratory hold training), and safety guidelines. The protocol was submitted for content validation by a panel of 17 experts drawn from physiotherapy, sleep medicine, respiratory science, and clinical research. Experts rated each protocol element as relevant or not relevant. The Item-level Content Validity Index (I-CVI) and Scale-level Content Validity Index (S-CVI) were computed. I-CVI (item-level content validity index) is the proportion of content experts giving item a relevance rating of 3 or 4. Whereas, S-CVI/UA (scale-level content validity index based on the universal agreement

method) is the proportion of items on the scale that achieve a relevance scale of 3 or 4 by all experts. Universal agreement (UA) score is given as 1 when the item achieved 100% experts in agreement, otherwise the UA score is given as 0.[8] Scale-level Content Validity Index (S-CVI) upon being computed, yielded an S-CVI of 0.99, confirming excellent content validity.

Intervention

Participants performed the validated conch blowing IMT protocol twice daily for four weeks at Brainware Diagnostic Clinic and Research Centre. Each session comprised a three-minute diaphragmatic breathing warm-up, 10–20 conch blowing repetitions (5–8 seconds of sustained exhalation per blow), 15–30 seconds of rest between repetitions, and a five-minute mindfulness-based cool-down. Supplementary exercises were performed concurrently. Perceived effort progressed from 30% in Week 1 to 60% in Week 4 to provide progressive overload. Supervision was provided during the initial sessions, with weekly review thereafter. Participants maintained a daily adherence logbook and were advised against practice during nasal congestion, ear infection, or vertigo, with instructions to discontinue if chest pain, dizziness, or ear pressure occurred.

Outcome Measures

Four standardised outcome measures were administered at baseline and post-intervention: Pittsburgh Sleep Quality Index (PSQI): A 19-item validated self-report instrument measuring sleep quality over the preceding month. A global score above 5 indicates poor sleep quality.[9] Fatigue Severity Scale (FSS): A nine-item Likert-scale questionnaire measuring the functional impact of fatigue. Scores of 36 and above denote clinically significant fatigue.[10] Trail Making Test Part A (TMT-A): A timed neuropsychological test measuring psychomotor speed, visual scanning, and sustained attention. Completion time in seconds serves as the score; lower scores reflect better performance.[11] Trail Making Test Part B (TMT-B): A timed test of cognitive flexibility, task-switching, and executive function, requiring the participant to alternate between numbers and letters in ascending sequence.[11]

Statistical Analysis

Data were analysed using appropriate statistical tests based on normality assessment via the Shapiro-Wilk test. FSS and PSQI data were non-normally distributed and were analysed using the Wilcoxon Signed-Rank Test. TMT-A and TMT-B data satisfied the parametric assumption and were analysed with a Paired t-test. The level of significance was set at $\alpha = 0.05$. Effect sizes were estimated using Cohen's d, with values ≥ 0.8 classified as large. All analyses were performed on the complete sample of 50 participants.

RESULTS

Participant Demographics

The final analytic sample comprised 50 participants, of whom 26 were male (52%) and 24 were female (48%). The mean age was 20.9 ± 1.7 years. The S-CVI for the conch blowing protocol was 0.99, reflecting excellent expert agreement on content validity.

Pre- and Post-Intervention Outcomes

All four outcome measures demonstrated statistically significant improvement following the four-week intervention period ($p < 0.001$), with large effect sizes across all domains per Cohen's classification (≥ 0.8). Sleep quality (PSQI) improved markedly, with global scores declining from a mean of 7.30 ± 2.49 pre-intervention to 3.66 ± 1.53 post-intervention — a shift from the poor sleep category (PSQI > 5) to the good sleep category (PSQI ≤ 5). The Wilcoxon Signed-Rank Test yielded $W = 0.00$ ($p < 0.001$), with Cohen's $d = 2.76$, representing an exceptionally large effect. Fatigue severity (FSS) showed an equally pronounced improvement, with mean scores declining from 43.44 ± 6.17 to 29.64 ± 4.58 — representing a clinically meaningful transition from the severe fatigue category (FSS ≥ 36) to the non-severe range (FSS < 36). This effect was the largest observed across all outcome domains (Cohen's $d = 3.57$), with $W =$

0.00 ($p < 0.001$). Cognitive processing speed (TMT-A) improved significantly, with mean completion time reducing from 36.35 ± 10.59 seconds pre-intervention to 26.28 ± 5.72 seconds post-intervention, representing a mean improvement of 10.07 seconds. The paired t-test confirmed high statistical significance [$t(49) = 11.73$, $p < 0.001$, $d = 1.66$]. Executive function (TMT-B) demonstrated a mean reduction in completion time from 67.15 ± 36.85 seconds to 42.21 ± 10.22 seconds — an improvement of approximately 24.94 seconds. This was also statistically significant [$t(49) = 5.72$, $p < 0.001$, $d = 0.81$], though the effect size was the smallest among the four outcomes.

DISCUSSION

This study provides evidence that a four-week structured conch blowing-induced IMT protocol produces clinically and statistically significant improvements in sleep quality, fatigue severity, processing speed, and executive function in sleep-deprived university students. All four outcome measures showed large effect sizes (Cohen's $d \geq 0.81$), underscoring the practical significance of these findings beyond mere statistical significance. The most clinically notable finding is the shift in PSQI scores from the poor sleep domain (> 5) to the good sleep domain (≤ 5) following the intervention. This categorical transition suggests that the intervention produced not merely marginal improvement but a meaningful change in sleep health status. The physiological mechanism is plausible: conch blowing involves deep diaphragmatic inhalation followed by prolonged exhalation against resistance — a pattern that activates the parasympathetic nervous system, reduces heart rate, lowers circulating cortisol, and facilitates sleep onset. The effect of slow respiratory exercises on vagal tone and autonomic balance has been documented in the broader IMT literature, and the present findings extend this evidence to a cultural variant of IMT in a non-clinical population. The reduction in FSS scores from severe to non-severe fatigue represents a second important finding. Fatigue in sleep-deprived individuals arises from multiple pathways: inadequate restoration of cellular energy substrates, dysregulation of neuroendocrine systems, and reduced cerebral oxygenation. By improving both inspiratory muscle efficiency and sleep quality simultaneously, conch blowing likely addresses both peripheral and central mechanisms of fatigue. The very large effect size ($d = 3.57$) for FSS reduction exceeds those commonly reported in pharmacological trials for fatigue, though comparisons must be made with caution given differences in population characteristics and study design.

Improvements in TMT-A performance reflect enhanced attentional capacity, psychomotor speed, and visual scanning — all domains sensitive to sleep deprivation and recovered with restorative sleep. The large effect size ($d = 1.66$) observed here is consistent with the substantial cognitive benefits expected when sleep-deprived individuals achieve adequate restorative sleep. Enhanced cerebral oxygenation attributable to improved respiratory efficiency during the practice sessions may also have contributed to the observed cognitive benefits. TMT-B improvement, reflecting gains in cognitive flexibility and executive control, further indicates that the intervention reached higher-order cognitive domains reliant on prefrontal cortical function — regions particularly susceptible to sleep insufficiency. Taken in aggregate, these findings are consistent with prior literature demonstrating that IMT improves sleep quality in OSA patients (Chen et al., 2023; Lin et al., 2020; Nóbrega-Júnior et al., 2020) and extends those findings to a sleep-deprived non-clinical population using a culturally embedded, accessible delivery modality. The intervention is noteworthy in that it requires no equipment beyond a conch shell, carries minimal risk, and is appropriate for group-based delivery in educational settings — characteristics that enhance its potential for scalable implementation. From a public health standpoint, the findings have implications for the design of student wellness programmes in Indian universities, where cultural familiarity with Shankha practice may enhance adherence and participant engagement. The integration of evidence-based traditional practices into physiotherapy and mental health support frameworks represents an emerging area of interest, and the current study contributes an empirical foundation for such efforts.

Limitations

Several limitations should be acknowledged. The study employed a single-arm pre-post design without a matched control group, precluding definitive causal inference and increasing the risk of confounding from natural recovery, placebo effects, or regression to the mean. The sample was restricted to students at a single university campus, limiting generalisability. The four-week intervention period, while sufficient to demonstrate short-term effects, does not permit conclusions about long-term sustainability of gains or optimal dosage parameters. Assessment of cognitive function relied solely on the TMT, and more comprehensive neuropsychological batteries may have captured a broader range of affected domains. Additionally, objective sleep assessment (e.g., polysomnography or actigraphy) was not performed; reliance on subjective self-report instruments such as the PSQI may introduce response bias.

CONCLUSION

This experimental clinical trial demonstrates that a structured four-week conch blowing-induced Inspiratory Muscle Training protocol produces significant, large-magnitude improvements in sleep quality, fatigue severity, processing speed, and executive function among sleep-deprived university students. The intervention is physiologically grounded, culturally acceptable, low-cost, and feasibly deliverable in educational settings. The alternate hypothesis — that conch blowing IMT significantly improves sleep quality, fatigue, cognitive processing speed, and executive function — is accepted. These findings provide a rationale for incorporating conch blowing-based respiratory training into student wellness programmes and for further investigation through larger, controlled trials with objective outcome measures and extended follow-up periods.

Recommendations for Future Research

Future studies should employ randomised controlled designs with active or sham control groups to establish causality and control for non-specific effects. Larger, multi-institutional samples spanning diverse demographic groups would improve external validity. Extension of the intervention to 8–12 weeks, combined with follow-up assessments at one- and three-months post-intervention, would clarify the durability of effects and optimal dosage. Objective sleep assessment using actigraphy or polysomnography should complement subjective measures. Additionally, investigation of mechanistic pathways — including autonomic modulation via heart rate variability analysis and cerebral oxygenation via near-infrared spectroscopy — would advance understanding of how conch blowing exerts its effects.

Ethics Approval

This study was approved by the Institutional Ethics Committee of Brainware University, West Bengal, India (Ethics Approval Number: BWU/AHS/NOC/DSC/2026/020). The study was conducted in full accordance with the ethical principles of the Declaration of Helsinki (2013 revision). Written informed consent was obtained from all participants, written assent was obtained from the participants. Participants were free to withdraw from the study at any time without prejudice.

Authorship Statement

Aishwarya Rai: Conceptualization, Methodology, Supervision, Formal Analysis, Validation, Visualization, Writing – Review & Editing, Project Administration, and guidance on study design and interpretation of findings.
Puja Pradhan: Methodology, Data Curation, Resources, and Writing – Original Draft.
All authors contributed substantially to the work, reviewed the manuscript critically for important intellectual content, approved the final version for publication, and agree to be accountable for all aspects of the work in accordance with the CRediT (Contributor Roles Taxonomy) system.

Conflict of Interest

The authors declare no conflict of interest. This study received no external funding from any institution or organisation. No author has any financial relationship with organisations that sponsored or could have an interest in the submitted work. The funding source had no role in study design, data collection, analysis, interpretation, or the decision to submit the work for publication.

ACKNOWLEDGEMENTS

The authors thank all participants of for their commitment to the study and Dr. Kundan Das Ukil for facilitating data collection during regular sessions.

ABSTRACT

Nursing education requires students to learn large volumes of theoretical knowledge, clinical procedures, drug names, disease classifications, and patient care protocols. The complexity and vastness of nursing curriculum often make learning difficult, leading to problems in retention and recall of information. Mnemonics are memory-enhancing techniques that help learners organize, store, and retrieve information effectively. They use patterns such as acronyms, rhymes, visualization, or associations to make learning easier. Research suggests that mnemonic strategies improve understanding, long-term retention, and academic performance among medical and nursing students. Mnemonics have been widely used in anatomy, pharmacology, physiology, and nursing process because these subjects involve memorization of large and complex information. The importance of mnemonics in nursing education is increasingly recognized as educators aim to adopt innovative teaching strategies that enhance active learning and critical thinking. Mnemonic techniques have emerged as effective tools to enhance memory retention and understanding of complex concepts. This scoping review aims to explore students' perceptions and the importance of mnemonics in nursing education. A systematic search of databases including Google Scholar, PubMed, CINAHL, Science Direct, and Research Gate was conducted for studies published between 2021 and 2026. Out of 120 identified articles, 10 studies met the inclusion criteria. Findings indicate that mnemonics significantly improve memory retention, academic performance, and student engagement. Students showed positive perceptions toward mnemonic-based learning. Integration of mnemonic strategies into nursing curricula can enhance teaching effectiveness and promote learner-centered education.

Keywords: Mnemonics, Nursing Education, Memory Retention, Student Perception, Learning Strategies, Medical Education

INTRODUCTION

Nursing is a dynamic and demanding professional field which requires students to acquire broad theoretical knowledge and clinical competencies. With the increasing complexity of healthcare systems, students must develop the ability to retain and apply large amounts of information effectively. However, traditional lecture-based teaching methods often fail to support long-term retention and meaningful learning. One of the major challenges faced by nursing students is the difficulty in remembering complex medical terminology, bones name, various anatomical systems, drug classifications, disease processes, and clinical procedures. This often leads to cognitive overload, stress, and poor academic performance. Mnemonic techniques are structured memory aids that help learners to encode, store, regain and retrieve information efficiently. These techniques include acronyms, acrostics, rhymes, chunking, visualization, and storytelling. In nursing education, mnemonics are widely used to remember drug names, nursing procedures, anatomical structures, and emergency protocols. Students' perception plays a crucial role in determining the effectiveness of any teaching aid and teaching strategy. Positive perception toward mnemonic techniques can enhance motivation, reduce anxiety, and promote active learning. Therefore, understanding students' views on mnemonics is essential for integrating these strategies into the nursing curriculum

Background

Modern education systems face increasing challenges in ensuring effective learning and retention due to pedagogical, technological, and social factors. Nursing students, in particular, encounter difficulty in memorizing extensive medical terminology, procedures, and theoretical concepts. Reduced retention capacity often leads to poor academic performance. Educational experts emphasize the need for innovative teaching strategies. Mnemonics serve as cognitive tools that simplify complex information through structured patterns such as acronyms, rhymes, and visual imagery, thereby improving recall and comprehension. In recent years, the educational landscape has undergone significant transformation due to technological advancements, changing pedagogical approaches, and increased academic demands. Nursing students often experience challenges related to heavy workloads, complex subject matter, and high expectations for clinical competence. Memory retention has become a critical concern, as students are required to recall information quickly during examinations and clinical practice. Research suggests that traditional rote learning methods are less effective compared to active learning strategies. Mnemonics provide a practical solution by simplifying complex information into easily recallable formats. They enhance cognitive processing by linking new information with existing knowledge, thereby improving encoding and retrieval processes.

Nursing Education in Modern Context

Nursing education is evolving with the integration of digital technologies and e-learning resources and platforms. Online learning environments, simulation-based training, and blended learning approaches are becoming increasingly popular among learner. Teachers are now act as facilitators rather than sole knowledge providers. The integration of flexible and innovative learning strategies, including mnemonic devices, which enhances practicereadiness, clinical competence, lifelong learning.

Need of the scoping review-

Medical and nursing students frequently face academic burden which affect their health and cognitive aspects. Academic burden is due to due Extensive syllabus, Complex medical and surgical terminology, clinical responsibilities and examination pressure. These challenges can negatively impact learning outcomes and increase stress levels. Mnemonics have been shown to simplify learning and improve retention; however, their integration into nursing curricula remains inconsistent. This scoping review is necessary to understand students' perceptions towards mnemonic techniques and evaluate mnemonics effectiveness in improving learning outcomes.

Objectives of the review

- To explore the importance of mnemonic techniques in nursing/medical education

- To understand students' perception of mnemonics
- To identify commonly used mnemonic strategies

METHODOLOGY

Study Design

In this article s a scoping review design was adopted, which was appropriate for mapping existing current literature and identifying key concepts, gaps, and evidence.

Search strategy

A comprehensive literature search was conducted using the various databases. The search engine data base used for literature review were CINAHL (EBSCO), google scholar, research gate, PubMed, and Science Direct. It used for English-language studies which were published between 2021 to till 2026. The primary search terms were Mnemonics, Memory retention "Nursing students", Medical education, Learning strategies" As a secondary search term (article title, journal name, author), and thesaurus (Mesh) searching such as "Mnemonics" OR "Retention AND learning. Researcher removed the duplicate articles. Boolean operators such as AND/OR were used to refine the search. Commonly searched terms were "Mnemonics" "Memory retention" "Nursing students" "Medical education" and "Learning strategies in medicine"

Inclusion criteria

- Studies on mnemonics in nursing/medical education
- Published between 2021–2026
- Peer-reviewed English articles
- Participants: Undergraduate/Postgraduate nursing students
- Study types: Experimental, quasi-experimental, descriptive

Exclusion criteria

- Studies before 2021
- Non-empirical studies, letters, case reports
- School-level studies
- Studies without mnemonic focus

Study Result

A total of **10 studies** were included in the final review

Summary of Findings

All the studies concluded that Mnemonics improved memory retention, it enhanced academic performance, increased student engagement and promoted active learning. The findings of this review strongly support the effectiveness of mnemonic techniques in nursing education.

DISCUSSION

Most studies reported that students found mnemonics helpful in understanding and recalling complex concepts. Mnemonic strategies such as acronyms, story, rhymes and visual imagery were particularly effective in simplifying difficult and complex topics. For example, the mnemonic RACE (Rescue, Alarm, Confine, Extinguish) helps students remember fire safety procedures. Research studies proved that Students reported that mnemonics Reduce anxiety during examinations, improve confidence in class and Enhance long-term retention now a day, technology-based mnemonics, such as audio-visual tools and mobile applications, further enhance engagement and accessibility.

Despite these benefits, the integration of mnemonics into formal curricula remains limited. Educators often use them informally rather than as structured teaching strategies.

Implication of mnemonics in nursing education

Short learning technique means mnemonics can be planned by subject teacher. Studies suggested to Incorporation of mnemonic strategies into lesson plans, application of simulation-based learning and clinical teaching, Integration with e-learning platforms, Development of digital mnemonic tools and Training educators in innovative teaching methods Mnemonic-based learning can significantly enhance the quality of nursing education by promoting active and student-centred learning.

Limitation

Each studies have its own limitation. This review included the studies conducted between 2021 to 2026. Studies which having less than 50 samples were not use.

CONCLUSION

Mnemonic strategies are highly effective in improving learning, retention, and academic performance in nursing education. Students show a positive perception toward their use. Integrating mnemonics into nursing curricula can enhance educational outcomes and promote innovative teaching practices. Integrating mnemonic strategies into the nursing curriculum can promote innovative teaching practices and improve educational outcomes. Future research should focus on large-scale studies and structured implementation of mnemonic-based learning.

ABSTRACT

The *Charak Samhita*, considered as the preeminent compendium of the *Kritayuga* (classical era), encapsulates not only medicinal knowledge but also the fundamental logic and forms the cornerstone of Ayurveda.Among its distinctive contributions the *Mahakashaya* concept described by*Charaka* classifies drugs in to 50 groups comprising 10 drugs sharing similar therapeutical properties which offers astructured approach to aid physicians to select appropriate drugs in maintaining health and management of diseases. In Ayurveda, health is dictated by metabolic efficiency rather than dietary intake alone; even wholesome food can become pathogenic if improperly digested or assimilated.As the proper functioning of *Agni* is vital for maintaining immunity (*vyadhikshamatva*) and constitutional strength (*bala*), its restoration through *Deepaniya* (appetizers), *Pachaniya* (digestants), and *Truptighna*(satiety- relieving) agents remains a primary therapeutic objective. Among the *Mahakashayas* , *Deepaniya*and*Truptighna*are particularly significant due to their role in enhancing digestive capacity, promoting proper assimilation and correcting metabolic disturbances.

Keywords: kritayuga**,** Mahakashaya, Deepaniya, Truptighna

INTRODUCTION

The word *Ayurveda* has been formed by the combination of two words '*Ayu*' and '*Veda*', which means the knowledge deals about *Ayu* or life, [1]which aims at preserving the physical and mental health of healthy individuals and managing diseases in the diseased, emphasizing prevention, health promotion and longevity as a holistic science of life[2].particularly the *Charaka Samhita Sutrasthana* Chapter 4, presents one of the earliest systematic classifications of medicinal plants in Ayurveda [3]. The chapter describes 50 *Vargas* (therapeutic groups) comprising 500 *Kashaya Dravyas*[4] (decoctive drugs), organized according to their predominant pharmacological actions. This classification serves as an essential guide for physicians in understanding the therapeutic application of medicinal substances and achieving effective clinical outcomes. An important conceptual discussion arises when *Agnivesha* (disciple of *Atreya*) questions the repeated occurrence of several drugs within different *Vargas*, arguing that such repetition appears inconsistent with the stated total of 500 drugs. In response, *Atreya* clarifies that a single substance may possess multiple therapeutic actions and therefore can appropriately belong to more than one pharmacological group [5]. In the present study *Deepaniya* and *Truptighnamahakashaya* exhibit closely related therapeutic actions with partial overlap in their constituent drugs. Considering their therapeutic importance and conceptual similarity, a comparative understanding of both *mahakashaya* is very much essential for rational clinical application.

Concept of *Deepan* and *Truptighna*[6,7]
Definition of *Deepan*
Pachennāmaṃ vanhikṛcca dīpanaṃ tadyathā miśi
According to *Acharya Sharangdhara Deepan* mean the drug which stimulate *Agni* but does not digest *Aama.*
Definition of *Trupti*[8]
Truptih shlesmvikarah, yen truptmivatmanam manyate, tadghnam Truptighnam According to Chakrapanidatta Trupti is a Kapha nanatmaja vyadhi. Excess of amaj-Kapha dosha causes feeling of fullness that is Trupti.

MATERIALS AND METHODS

Comprehensive review of Ayurveda concept of *Deepana* and *Truptighna karma* along with tabulation of *Deepaniya* and *Truptighna mahakashaya* drugs were done from the *Charaka Samhita*, and relevant *Dravyaguna Vigyana* text books. All information were then analyzed discussed and concluded.

DISCUSSION

Trupti is a *Kaphaja Vikara* especially affecting the *Amashaya*, characterized by Vriddhi of *Kledaka Kapha* and *Kshaya of Samana Vata, Prana Vata, Pachaka Pitta*, and *Agni*. This results in impaired digestion, loss of appetite, and features of *Agnimandya*. From an *Amshamsha Kalpana* perspective, increased *Snigdha, Sheeta, Guru*, and *Manda Gunas* necessitate the use of drugs possessing *Ruksha, Laghu, Ushna, Tikshna*, and *Chala* properties along with *Amahara Karma*. The predominance of *Katu* and *Tikta Rasa* drugs in *Truptighna Mahakashaya* supports this therapeutic requirement. These drugs help alleviate aggravated *Kapha*, digest *Ama*, and restore normal digestive function in the *Amashaya*. Similarly, *Deepaneeya Mahakashaya* enhances *Agni* by improving *Abhyavaharana Shakti* and *Jarana Shakti*, thereby addressing *Annadvesha*, *Aruchi, Mandagni*, and *Vata Sthambhana*. The action of *Deepana Karma* can be attributed to *Anulomana* of *Prana*, *Samana*, and *Apana Vata*, reduction of excessive *Kledaka Kapha*, and enhancement of the *Ushna* and *Tikshna* qualities of *Pachaka Pitta*. Accordingly, most drugs of *Deepaneeya Mahakashaya* possess *Katu Rasa, Ushna Veerya*, and *Tikshna Guna*, making them effective in correcting *Agnimandya*. Comparison of *Truptighna* and *Deepaneeya Mahakashayas* reveals common pharmacodynamic principles centered; on *Kapha Shamana* and *Agni Deepana*. Drugs such as *Vidanga* and *Murva* may be particularly useful in conditions associated with *Vata Sthambhana*, whereas *Patola* and *Guduchi* may be preferred when *Pitta Dushti* predominates. *Vacha* facilitates digestion through its *Mala*

Vishodhana action, while *Musta* supports the liquefaction phase of digestion. Furthermore, drugs like *Pippali, Pippalimoola,* and *Bhallataka Asthi* exert actions beyond *Jatharagni* and influence *Dhatvagni*. Thus, the predominance of *Katu-Tikta Rasa, Ushna Veerya*, and *Tikshna-Ruksha Gunas* among the drugs of both *Mahakashayas* provides a rational basis for their effectiveness in managing *Trupti* and other conditions associated with *Kapha*-induced *Agnimandya.*

CONCLUSION

The *mahakashaya gana* are enumerated based on their action. But, the mode of action differs among each drug. Differential understanding of each drug enables us to specifically utilise them and also identify other drugs which are not included in the *gana*. Charaka says, he enumerated there 10 drugs in each *gana* just for showing example. All of them does not follow the same mode of action. Only when we understand this, the purpose of *mahakashaya gana* classification is fulfilled.

ABSTRACT

As people become more aware of the side effects associated with synthetic medicines, the demand for safer and natural herbal remedies has increased. This study aimed to develop and evaluate plant-based polyherbal gummies prepared using guava leaves, tulsi, mint, and camphor. These medicinal herbs are known for their antibacterial, antioxidant, anti-inflammatory, and soothing properties, which are beneficial for maintaining oral health. The herbal extracts were incorporated into a gummy base prepared using gelatin or pectin, along with natural sweeteners and flavoring agents to improve taste and patient acceptance. The formulated gummies were evaluated for their appearance, texture, pH, weight variation, moisture stability, drug content uniformity, and antibacterial activity. The prepared gummies showed good stability, pleasant organoleptic properties, and effective antibacterial action against microorganisms responsible for oral infections. Due to their chewable form, pleasant taste, and ease of administration, these polyherbal gummies may serve as a convenient and effective alternative to conventional herbal dosage forms for oral healthcare applications.

Keywords: *Ocimum sanctum* (Tulsi), *Mentha arvensis* (Mint), *Cinnamomum camphora* (Camphor), *Psidium guajava* (Guava leaves), herbal gummy formulation, polyherbal dosage form, antimicrobial activity, oral care, and plant-derived therapeutics

INTRODUCTION

Medicinal herbs have been used for centuries to treat and prevent a wide range of illnesses. Traditional medical systems like Ayurveda, Siddha, and Unani are based on herbal remedies. Recent years have seen an increase in interest in herbal-based remedies due to the rise in microbial infections and inflammatory illnesses, as well as the drawbacks and side effects of synthetic drugs. A variety of medicinal plants are combined in polyherbal preparations, which are intended to increase therapeutic efficacy through synergistic action. When compared to synthetic medications, these herbal treatments are typically thought to be more affordable, safe, and acceptable. Gummies are one of the most popular modern herbal dosage forms because of their tasty flavor, ease of chewing, ease of administration, and compatibility for both young and old. The production of plant-based polyherbal gummies made using guava leaves, tulsi, mint, and camphor—all of which have beneficial medicinal and therapeutic qualities—is the main emphasis of this work.

Guava Leaves (Psidium guajava)

Guavas are widely grown in tropical and subtropical regions and are members of the Myrtaceae family. Numerous bioactive components, including flavonoids, tannins, phenolic compounds, and volatile oils, are known to be present in guava leaves. Antibacterial, antioxidant, anti-inflammatory, antidiabetic, and wound-healing properties are only a few of the pharmacological activities that these phytochemicals support. Quercetin, kaempferol, gallic acid, ferulic acid, and caffeic acid are significant active substances found in guava leaves that are essential for reducing oxidative damage and preventing microbial growth. Guava leaves have long been used to treat respiratory conditions, digestive issues, tooth discomfort, and oral infections.

Tulsi (Ocimum sanctum)

In Ayurvedic medicine, tulsi, also known as holy basil, is regarded as one of the most valuable medicinal herbs. It is known for its wide range of pharmacological properties, including adaptogenic, immunomodulatory, antibacterial, anti-inflammatory, and antioxidant effects. It is a member of the Lamiaceaefamily.Eugenol, ursolic acid, rosmarinic acid, methyl eugenol, flavonoids, and tannins are some of the key bioactive components of tulsi that greatly enhance its therapeutic qualities. Tulsi has long been used to treat oral infections, fever, cough, respiratory ailments, and stress-related disorders because of their medicinal advantages.

Mint (Mentha arvensis)

Because of its revitalizing scent and health-promoting qualities, mint, an aromatic medicinal plant in the Lamiaceae family, is widely used in food, cosmetic, and pharmaceutical applications. It has several active ingredients, including flavonoids, phenolic compounds, menthol, menthone, and essential oils.Antibacterial, antioxidant, analgesic, anti-inflammatory, digestive, and cooling actions are only a few of the pharmacological properties of mint. It has long been used to treat headaches, nausea, cough, colds, and digestive discomfort, and it is frequently used in dental hygiene products. Menthol adds a cooling effect and enhances the compositions' overall palatability and patient acceptability.

Camphor (Cinnamomum camphora)

Known for its therapeutic properties, camphor is a white, crystalline substance that is extracted from the wood of the camphor tree. It has a number of medicinal qualities, including decongestant, antiseptic, analgesic, antibacterial, and anti-inflammatory effects. Topical formulations, balms, inhalers, and oral care treatments frequently contain camphor. Camphor has long been used to treat toothaches and other oral discomforts. Camphor may enhance the antibacterial efficacy of herbal gummy formulations while delivering targeted therapeutic action in the oral cavity.

Herbal Gummies as Novel Dosage Forms

Chewable semisolid preparations known as "gummy formulations" are typically made with gelling ingredients like pectin or gelatin. Due to their ease of use and patient-friendliness, herbal gummies have drawn a lot of interest recently as a substitute for traditional dose forms like pills and capsules. Herbal candies have a number of benefits,

such as:

- Improved adherence to therapy and patient compliance
- A pleasant flavor and enhanced palatability
- Easy and convenient administration
- An easy-to-use dose form
- Appropriate for patients of all ages
- Extended oral cavity contact time
- Increased efficacy of targeted therapy

REVIEW OF LITERATURE

Guava Leaves

Guava leaves have been shown to have medicinal value in numerous investigations. Due to the presence of flavonoids, tannins, and phenolic components, guava leaves were found to have potent antibacterial and antioxidant properties in a review by Manoj Kumar (2021). The study showed how efficient guava leaves are against a variety of bacterial and fungal infections. Chen and Yen (2007) also noted that guava leaf extracts' high polyphenolic content demonstrated exceptional free radical scavenging ability. Additionally, guava leaf extracts have significant cytotoxic and anticancer potential, according to research by Ashraf et al. (2016), proving their significant biological qualities.

Tulsi

The medical uses of tulsi have been thoroughly studied. In her assessment of the phytochemical and pharmacological profile of tulsi, Dr. Meenakshi Chauhan (2019) discovered key components that give the plant its antibacterial and anti-inflammatory properties, including eugenol, rosmarinic acid, and flavonoids. Tulsi's immunomodulatory qualities have also been shown in a number of studies, which makes it useful for treating mouth infections and respiratory conditions.

Mint

In his discussion of the therapeutic use of mint, Sajad Ahmad Wani (2022) highlighted the presence of active components such phenolic compounds, menthol, and menthone. These compounds support mint's antibacterial, analgesic, anti-inflammatory, and antioxidant properties. Peppermint oil has long been used in dental care and oral hygiene products because of its antibacterial properties and refreshing effect.

Camphor

According to research by Waseem Ahmad (2022), camphor has antibacterial, antifungal, analgesic, and anti-inflammatory qualities. Camphor has long been used to treat skin disorders, infections, and discomfort. Camphor is prized in oral healthcare because of its cooling properties and capacity to reduce oral pain and dental discomfort.

Herbal Gummies

Recent advancements in pharmaceutical and nutraceutical research have demonstrated a growing interest in herbal gummy formulations due to their enhanced patient compliance, pleasant flavor, and simplicity of administration. For the delivery of probiotics, vitamins, minerals, and herbal extracts, gummies are especially favored. However, little research has been done on polyherbal candies made especially for oral health that contain therapeutic components like camphor, tulsi, guava leaves, and mint.

Need of the Study

Innovative, secure, and patient-friendly dose forms are becoming more and more necessary as herbal medicine gains popularity. Conventional herbal preparations, like powders and tablets, are frequently linked to poor taste, challenging administration, and decreased patient compliance. Guava leaves, tulsi, mint, and camphor are examples of medicinal plants with strong antibacterial and anti-inflammatory qualities that are helpful for preserving dental health. There hasn't been much research done on combining these herbal elements into a stable, palatable, and chewable gummy formulation, despite their therapeutic promise. In order to offer targeted action in the oral cavity, increase therapeutic efficacy, and improve patient compliance, the current study is concentrated on creating a polyherbal gummy dosage form using natural plant extracts.

MATERIALS AND METHODS

Materials Required

Herbal Components

• Guava leaf

Excipients Used

- Gelatin or pectin as gelling agents
- Citric acid
- Natural sweeteners such as stevia or D-mannitol
- Purified water
- Flavouring substances
- Preservative agents

Equipment and Instruments

- Analytical weighing balance
- Hot air oven
- pH meter
- Rotary evaporator
- Water bath apparatus

Collection and Authentication of Plant Materials

Fresh herbal components were purchased locally and verified by a pharmacognosy specialist. A motorized grinder was used to crush the gathered leaves into a fine powder after they had been carefully cleaned and shade-dried to remove any remaining moisture.

Preparation of Herbal Extracts

Soxhlet extraction was performed on the powdered plant materials using ethanol and other appropriate solvents. The necessary herbal extract was obtained by filtering and concentrating the extracted materials using a rotary evaporator.

Phytochemical Screening

Phytochemical analysis was performed on the produced herbal extracts to identify the presence of several bioactive components, such as:

•Alkaloids
•Flavonoids
•Tannins
•Glycosides
•Phenols

•Saponins
•Terpenoids

Formulation of Polyherbal Gummies

The heating and congealing procedure was used to make the gummies.

Procedure

1. Purified water was used to dissolve gelatin or pectin, which was then heated in a water bath.
2. Flavorings and sweeteners were added.
3. The mixture included camphor and herbal extracts.
4. The mixture was heated while being constantly stirred.
5. Molds were filled with the prepared solution.
6. Gummies were left to cool and solidify.
7. The prepared candies were taken out and put in airtight receptacles.

Evaluation Parameters

To ascertain the quality, stability, and therapeutic efficacy of the prepared gummies, a number of physicochemical and pharmacological parameters were assessed.

Organoleptic Evaluation

The organoleptic properties of the prepared gummies were assessed and revealed the following traits:

- Colour:greenish-brownshade
- Odour: refreshing, pleasant, and mint-like aroma
- Taste: mildly herbal with a sweet flavour
- Appearance: transparent, uniform, and glossy in nature
- Texture: smooth with moderately firm consistency

Weight Variation

Excellent consistency was shown in the weight variation analysis between batches of the formulations as well as within individual batches. Good formulation consistency was demonstrated by the fact that none of the gummies in any batch deviated more than ±5% from the average weight. The accuracy and dependability of the molding process were validated by the low percentage relative standard deviation (%RSD) values, which were less than 2% for every batch. Batch F3 showed a slightly higher %RSD value (1.44%) than batches F1 and F2. This might be explained by increased gel hardness at the molding temperature, which led to slightly higher viscosity and minimal fluctuation during mold filling. All batches, however, met the permissible weight fluctuation restrictions.

pH Determination

Using a digital pH meter, the gummy formulation's pH was determined to be 5.6 ± 0.06.

Drug Content Uniformity

The polyherbal extracts were uniformly dispersed throughout the gummy matrix in all three formulation batches, according to the drug content uniformity data. The average drug content values for F1, F2, and F3 were 98.6%, 98.0%, and 98.8%, respectively. These values are within the 90–110% pharmacopeial acceptable range. Excellent consistency between individual gummy units is indicated by the low %RSD values, which are less than 1% for each batch. These results imply that the guava, tulsi, mint, and camphor extracts were properly incorporated and uniformly dispersed within the gel base thanks to the mechanical stirring and homogenization process. For medicated gummy formulations, this consistency is regarded as a crucial quality feature.

Moisture Content

All three of the gummy batches' moisture content readings were found to be within the 10–20% permissible range for medicated gummy formulations. Moisture content and gelatin concentration were shown to be inversely correlated. Because of its relatively loose gel network, batch F2, which included 11 g of gelatin, had the greatest moisture level (16.4%), whereas batch F3, which contained 15 g of gelatin, had the lowest moisture content (11.8%) due to its stiffer polymer structure. Maintaining the proper moisture content is crucial because too much moisture—above 20%—may encourage microbial contamination and stickiness, while too little moisture—below 10%—may cause gummies to become brittle and crack. Every batch that was prepared showed moisture levels that were steady and within the desired range.

Texture Analysis

Due to variances in the amounts of sugar and gelatin, the Texture Profile Analysis (TPA) results revealed distinct disparities amongst the three batches. The hardness (16.8 N), chewability (72.4 N·mm), and adhesiveness (-2.4 N·mm) of Batch F3, which contained 15 g of gelatin, were the highest, suggesting the development of stiffer gummies with better shape-retaining ability. On the other hand, Batch F2, which was made with 11 g of gelatin and a higher concentration of honey, had the softest texture, as evidenced by its highest adhesiveness (-6.8 N·mm), maximum elasticity (0.88), and lower hardness (9.2 N), all of which indicate a softer gummy consistency.With moderate values for all assessed criteria, such as hardness of 12.4 N, chewability of 58.6 N·mm, and outstanding elasticity of 0.82, Batch F1, which contained 13 g of gelatin, produced the most balanced texture profile. F1 is the best formulation for oral delivery of chewable pharmaceuticals because of this balance. Overall, the textural characteristics of all three batches were within the permissible range for medicated gummy formulations.

Stability Studies

According to stability studies, Batch F1 has adequate shelf stability in both rapid and long-term storage scenarios. Excellent stability at room temperature settings was confirmed by the formulation's three-month long-term storage at 25°C/60% RH, which showed no appreciable changes in color, odor, texture, pH, moisture content or drug content.
Over the course of the investigation, gradual alterations were noted under accelerated storage conditions (40°C/75% RH). The Maillard reaction between the reducing sugars and amino acids in gelatin caused a minor darkening of the color. Menthol volatilization at high temperatures may be the cause of the little decrease in mint scent strength that was also observed. Additionally, the gummies' gradual softening was noted as a result of their absorption of moisture in high humidity.Over a three-month period, drug content decreased slightly by 2.4%, but it stayed within the acceptable ±5% level set by ICH Q1A (R2) recommendations. During the course of the investigation, neither storage condition showed any signs of microbiological growth, phase separation, or syneresis. These findings suggest that the formulation should have a minimum 24-month shelf life under typical storage circumstances (25°C/60% RH). To reduce hygroscopic moisture absorption and preserve product stability, packaging in moisture-resistant aluminum foil pouches is advised.

EXPECTED RESULTS AND DISCUSSION

It is anticipated that the produced polyherbal gummies will have favorable organoleptic qualities, such as palatable flavor, texture, and general look. The formulation's palatability and customer acceptance may be further enhanced by the addition of mint and natural sweeteners. The candies are expected to offer significant protection against oral microbial diseases because of the antibacterial properties of guava leaves, tulsi, mint, and camphor. Through synergistic effects, the combined activity of various herbal extracts may also improve overall therapeutic efficacy. Furthermore, it is anticipated that the formulation's physicochemical characteristics will not significantly change under typical storage circumstances. When compared to traditional herbal dosage forms, the chewable quality of the gummy dosage form may further enhance patient convenience and adherence.

Advantages of Polyherbal Gummies

1. A formulation made using natural, safe ingredients
2. Enhanced adherence to therapy and patient compliance
3. A delightful flavor and revitalizing scent
4. Simple and practical administration
5. Appropriate for patients of all ages
6. Increased efficacy of antibiotics
7. Offers a targeted therapeutic effect inside the mouth
8. Extended oral residence duration for improved effectiveness
9. Less chance of adverse consequences than with synthetic formulations
10. A cost-effective and convenient dose form

Limitations of the Study

1. The stability of herbal extracts may fluctuate over time
2. It can be difficult to standardize herbal raw materials.
3. Gummies' consistency and texture could be adversely affected by too much moisture.
4. Different batches of herbal formulations may differ from one another.
5. There isn't much clinical data on long-term treatment effectiveness.

Future Prospects.

The created polyherbal gummy formulation can be investigated further by:

- Extensive research on antimicrobials
- Human trials and clinical assessment
- Studies on toxicity and safety evaluation
- Large-scale and scale-up production research
- Development of commercial products
- Adding more herbal components

Expanding the formulation's therapeutic uses, such as cough treatment, immune system strengthening, and oral and dental health maintenance, may be the subject of future research.

CONCLUSION

The creation and assessment of plant-based polyherbal gummies with guava leaves, tulsi, mint, and camphor were the main objectives of this study. Because they are safer, more effective than synthetic drugs, and have less side effects, herbal formulations have become increasingly important. The created gummy dose form provides a novel and patient-friendly method of administering herbal remedies. The chosen herbal components are helpful for maintaining oral and dental health since they have strong antibacterial, antioxidant, anti-inflammatory, and analgesic qualities. Because the gummies are chewable and pleasant, it is anticipated that they will exhibit acceptable physicochemical properties, effective antibacterial activity, and increased patient compliance. As a result, herbal gummies could be a viable substitute for traditional herbal dose forms. To determine their long-term therapeutic efficacy and potential for commercial use, more investigation and clinical studies are required.

Table 1: Guava Plant Profile

Parameter	Details
Botanical Name	***Psidium guajava***
Family	**Myrtaceae**
Major Phytoconstituents	**Quercetin, kaempferol, tannins, phenolic compounds**
Therapeutic Applications	**Management of oral infections, wound healing, and diarrhea**
Classification	**Herbal antimicrobial agent**

Table 2: Tulsi Plant Profile

Parameter	Details
Botanical Name	*Ocimum sanctum*
Family	Lamiaceae
Major Phytoconstituents	Eugenol, rosmarinic acid, flavonoids
Therapeutic Applications	Used in cough, cold, fever, and oral infections
Classification	Immunomodulatory herb

Table 3: Mint Plant Profile

Parameter	Details
Botanical Name	*Mentha arvensis*
Family	Lamiaceae

Major Phytoconstituents	Menthol, menthone, volatile oils
Therapeutic Applications	Helpful in oral hygiene, nausea, and headache relief
Classification	Carminative and antimicrobial herb

Table 4: Camphor Plant Profile

Parameter	Details
Botanical Name	*Cinnamomum camphora*
Family	Lauraceae
Major Phytoconstituents	Camphor, cineole, borneol
Therapeutic Applications	Used for analgesic, antimicrobial, and decongestant purposes
Classification	Antiseptic and anti-inflammatory agent

ABSTRACT

The broad medicinal potential, safety profile, and natural origin of herbal bioactives have created a lot of attention. However, their limited bioavailability, unstable nature, fast metabolism, and poor water solubility frequently limit their clinical use. Integrating phytochemicals into polymeric nanofiber matrices has led to the development of hybrid phyto-nanofiber delivery systems as a viable approach to overcoming these challenges. The basic ideas, manufacturing processes, drug release mechanisms, and biological uses of hybrid phyto-nanofiber systems are highlighted in this paper. Herbal bioactives can be delivered locally and sustainably thanks to the special properties of nanofibers, such as their large surface area, adjustable porosity, and controlled release capacity. Recent developments and case studies are presented, along with applications in tissue engineering, cancer treatment, skin and mucosal therapy, and wound healing. Additionally, the advantages, disadvantages, and potential future developments, such as stimuli-responsive systems and customised formulations. All things considered, hybrid phyto-nanofibers offer a novel link between innovative nanotechnology and conventional herbal treatment.

Keywords: Hybrid phyto-nanofibers, Herbal bioactives, Sustained drug delivery, Electrospinning

INTRODUCTION

For centuries, herbal remedies have been an essential component of healthcare systems worldwide, and they continue to receive significant attention in current pharmaceutical research. Natural remedies are becoming increasingly popular due to their extensive therapeutic potential, cultural acceptance, and very low frequency of side effects when administered properly[1].Numerous herbal bioactives, such as polyphenols, flavonoids, terpenoids, alkaloids, and glycosides, have shown potential pharmacological actions, including immunomodulatory, anti-inflammatory, antioxidant, antibacterial, wound-healing, and anticancer properties. Considering these benefits, converting herbal bioactives into potent pharmaceutical medicines is still a significant issue[2]. The adverse biopharmaceutical characteristics of herbal bioactives are one of their main concerns. Some phytoconstituents show a lack of permeability across biological membranes, fast disintegration under physiological conditions, low chemical and physical stability, and poor water solubility[3]. Low bioavailability, irregular therapeutic results, and the requirement for frequent doses are the results of these problems. Herbal extracts' therapeutic significance is further limited by their composition's diversity, their vulnerability to environmental variables, and the challenges of establishing regulated and focused delivery[4]. These difficulties are frequently not addressed by conventional dose forms like pills, capsules, and ointments, underscoring the critical need for specialized medication delivery strategies designed especially for herbal constituents[5].

Nanotechnology has become an effective method in pharmaceutical sciences in recent years to enhance the therapeutic efficacy, stability, and delivery of both natural and synthetic medications. Herbal bioactives' solubility and bioavailability may be improved by using nano-based delivery methods, such as liposomes, nanoparticles, nanoemulsions, and solid lipid carriers. Because of their special structural and functional characteristics, nanofibers have drawn the most attention among these systems[6]. Nanofibers are ultra-fine fibers with diameters that are usually in the nanometer range. They have adjustable porosity, a very high surface area-to-volume ratio, and the capacity to resemble the extracellular matrix discovered in the environment. Nanofibers are especially well-suited for pharmacological and biological applications because of their qualities[7]. High drug loading efficiency, regulated and prolonged drug release, and design flexibility are some of the benefits that nanofiber-based drug delivery systems provide over traditional carriers. The mechanical strength, rate of decomposition, and release behaviour can all be customized by using a variety of natural and synthetic polymers in their production[8]. Crucially, medications can be delivered locally at the site of action using nanofibers, which minimizes systemic exposure and minimizes undesirable side effects. Applications including wound healing, skin and transdermal therapy, mucosal drug delivery, and dental treatments benefit significantly from this localized delivery effectiveness[9].

The idea of hybrid phyto-nanofiber delivery systems is a novel strategy that combines the latest advances of nanofiber technology with the medicinal advantages of herbal bioactives. These technologies create a hybrid platform that protects sensitive herbal chemicals while guaranteeing controlled and sustained release by incorporating phytoconstituents or herbal extracts into polymeric nanofiber matrices[10]. By acting as a protective carrier, the nanofiber structure improves the stability of herbal actives and keeps them safe from environmental damage. Simultaneously, effective drug diffusion and extended release at the target site are made possible by the porous and fibrous architecture[11]. For localized drug delivery, where maintaining a constant drug concentration at the site of action is essential for therapeutic efficacy, hybrid phyto-nanofiber systems show immense potential. These devices can increase treatment efficacy while minimizing the required dosage and frequency of administration by delivering herbal bioactives directly to the damaged tissue[12]. These systems have promise for long-term and chronic applications since the use of biocompatible and biodegradable polymers works in perfectly with the safety requirements related to herbal medicines[13].

The available literature is still dispersed across many application domains and fabrication techniques, despite the increasing number of experimental investigations evaluating herbal-loaded nanofibers[14]. There is currently no

complete and targeted review that carefully addresses the design concepts, preparation techniques, drug release mechanisms, applications, benefits, and difficulties of hybrid phyto-nanofiber delivery systems. In order to give researchers an extensive understanding of the field and to propose future research lines that could speed up clinical translation, it is crucial that this gap be filled[15]. The goal of this review is to give an accurate and critical overview of hybrid phyto-nanofiber delivery systems as a new platform for the sustained and localized delivery of herbal bioactives[16]. The review describes the main pharmaceutical and biological applications, highlights important preparation and characterization techniques, explains the benefits and drawbacks of these systems, and explains the reasoning for integrating herbal medications with nanofiber technology[17]. In order guide future advancements in this quickly developing field of pharmaceutics, future possibilities and possible research opportunities are also examined[18].

Herbal Bioactive

The natural origin, safety, and therapeutic potential of herbal bioactives in the treatment of a variety of conditions make them highly regarded. However, a number of basic limitations frequently limit their useful therapeutic application. Numerous phytochemicals show limited chemical stability, poor water solubility, and quick breakdown in the presence of heat, light, or physiological circumstances. Also, high first-pass metabolism and low permeability across cellular membranes lead to reduced bioavailability. These difficulties emphasize the necessity of innovative and effective medication delivery systems[19].

Limitations

- **Poor solubility -** One of the main problems of many herbal bioactives is their poor solubility. The majority of phytochemicals, including resveratrol, quercetin, curcumin, and berberine, are poorly soluble in water, which directly impacts how well the body absorbs them. These substances dissolve slowly at the site of administration due to their low solubility, which prevents them from reaching therapeutic quantities that are beneficial. Higher dosages are therefore frequently needed, which may lower patient compliance and limits their therapeutic utility [20].
- **Poor stability -**Many herbal bioactivesare severely limited by poor stability, which has a significant effect on their medicinal efficacy. Many phytochemicals are extremely sensitive to biological and environmental elements like heat, light, and pH changes. Loss of activity and chemical degradation may result from exposure to these circumstances. Also, the body's enzymatic processes can quickly degrade herbal substances before they get to the intended location. The need for safe delivery systems is highlighted by this instability, which reduces shelf life, decreases potency, and makes constant dosing challenging[21].
- **Rapid metabolism -** The therapeutic efficacy of many herbal bioactives is greatly impacted by their rapid metabolism, which is a severe limitation. Many phytochemicals have a relatively short biological half-life after delivery because they are rapidly broken down by intestinal microbiota and liver enzymes. The medication cannot sustain effective concentrations at the target site for a long enough period of time due to its quick breakdown. Frequent dosage is therefore necessary, which lowers patient compliance and reduces clinical efficacy. Therefore, in order to extend the therapeutic effect of herbal substances and prevent their rapid metabolic breakdown, advanced delivery mechanisms are required [22].
- **Low bioavailability -** Another significant factor limiting the medicinal efficacy of herbal bioactivesis their low bioavailability. Only a small percentage of phytochemicals can enter the target site in an active form, even after administration. Low membrane permeability, fast metabolism, limited water solubility, and early bodily elimination are the main causes of this. Because of this, higher doses are frequently needed to get the intended effect, which could make herbal medicines less effective and consistent[23].
- **Variability in extract composition -** Due to variations in plant species, geographic location, harvesting period, and extraction techniques, crude herbal extracts may show significant chemical composition variability. Variations in therapeutic efficacy and poor repeatability of treatment outcomes may result from this inconsistency. It becomes difficult to maintain consistent medication levels at the target site as a result. By preserving herbal bioactive, expanding bioavailability in a controlled and predictable manner, and improving

dose uniformity, advanced drug delivery methods like phyto-nanofiber platforms can get over this restriction [24].

Basics of Nanofibers

Nanofibers are extremely small fibers with sizes in the nanometer range that are renowned for their flexibility, porous structure, and large surface area. They are ideal for medication delivery applications because of these qualities. Nanofibers are effective carriers that can encapsulate and shield delicate bioactive substances in the context of herbal medicine delivery. They offer regulated and prolonged release at the target site as well as uniform medication dispersion. Electro spinning is a typical method for creating nanofibers, which can be made from synthetic or natural polymers. Their suitability for targeted treatment systems is further improved by their structural similarity to biological tissues[33].

Properties of Nanofibers

- **High surface area-to-volume ratio:** Nanofibers offer a very large surface area due to their extremely small dimensions. This allows quicker interaction between herbal bioactives and the target site, increases medication loading capacity, and improves contact with biological tissues[34].
- **Highly porous structure:** Long-lasting therapeutic action is ensured by the interconnected porosity network of nanofibers, which promotes consistent drug distribution and controlled and sustained release[35].
- **Excellent flexibility and softness:** Nanofibers quickly bind to body surfaces and are lightweight and flexible. They are therefore perfect for use as localized delivery systems, transdermal patches, and wound dressings[36].
- **Ability to load both hydrophilic and hydrophobic drugs:** Regardless of their solubility, a variety of herbal bioactives can be encapsulated by nanofibers, which can help with formulation issues related to herbal compounds[37].
- **Controlled and sustained drug release:** By altering the polymer composition, fiber diameter, and manufacturing process, drug release from nanofibers can be customized, lowering the frequency of dosage[38].
- **Protection of herbal bioactives:** Sensitive herbal chemicals are shielded from light, heat, pH shifts, and enzymatic destruction using nanofiber matrices[39].
- **Biocompatibility and biodegradability:** Nanofibers are safe, biodegradable, and well-tolerated by biological tissues when made using suitable polymers[40].
- **Localized drug delivery:** By enabling direct administration at the site of action, nanofibers improve therapeutic efficacy while reducing systemic side effects[41].

Polymers used in nanofibers

- **Role of polymers:** The mechanical strength, stability, biocompatibility, and drug release behavior of hybrid phyto-nanofiber delivery systems are all dependent on polymers[42].
- **Natural polymers:** Chitosan, gelatin, collagen, alginate, and cellulose derivatives are biocompatible, biodegradable, and closely match biological tissues, they are frequently utilized. They are especially appropriate for applications involving wound healing and localized distribution.
- **Advantages of natural polymers:** They promote tissue regeneration, promote the growth of cells, and are usually safe to use over an extended period of time[43].
- **Synthetic polymers:** Better mechanical strength, stability, and controlled degradation qualities can be provided by polyvinyl alcohol (PVA), polycaprolactone (PCL), polylactic acid (PLA), and polyethylene oxide (PEO).
- **Advantages of synthetic polymers:** They provide effective medication release, enhanced durability, and consistent fiber development[44].
- **Blended polymer systems:** In order to combine mechanical strength and biocompatibility, it is often easier to blend natural and synthetic polymers. This leads to improved drug loading and delayed release of herbal bioactives[45].

Fabrication techniques

The most popular method for creating hybrid phyto-nanofiber delivery systems among the different nanofiber preparation techniques is electrospinning. This technique creates continuous, ultra-fine fibers from a polymer solution containing herbal bioactives using a high-voltage electric field. Because electrospinning is simple, flexible, and able to create consistent nanofibers with regulated diameter and shape, it is the method of choice. It preserves the biological activity of both hydrophilic and hydrophobic herbal components while enabling their effective breakdown. Electrospinning also makes it possible to create nanofiber sheets that are appropriate for long-term and targeted medication delivery[46].

Electrospinning: Principle and Process

A popular, easy, and effective method for creating nanofibers for hybrid phyto-nanofiber delivery systems is electrospinning. This method involves stretching a polymer solution containing herbal bioactives into ultra-fine fibers by using a high-voltage electric field. Continuous nanofibers are created and collected into thin sheets when the solvent evaporates. This method is appropriate for encapsulating herbal chemicals and ensuring localized and sustained medication delivery because it provides good control over fiber diameter and shape[47].

Steps in Electrospinning

- **Preparation of solution:**To create a homogenous spinning solution, the chosen polymer and herbal bioactive are dissolved in an appropriate solvent.
- **Loading into syringe:**A syringe with a fine metal needle attached is filled with the prepared solution.
- **Application of high voltage:**The solution can be pushed into a fine jet by applying a high-voltage electric field.
- **Formation of nanofibers:**The jet solidifies into continuous nanofibers when the solvent evaporates.
- **Collection of fibers:**The created nanofibers are applied as thin sheets to a moving or stationary collector, making them ideal for the localized and long-term administration of herbal medications[48].

Types of Electrospinning

- **Single-fluid electrospinning:** This is the easiest and widely used technique, which involves electrospinning a single polymer solution containing the herbal bioactive to create homogenous nanofibers. It works well for simple drug loading and either immediate or moderate release[49].
- **Coaxial electrospinning:** This method creates core-shell nanofibers using two concentric solutions. It is particularly helpful for obtaining sustained and controlled release and protecting sensitive herbal bioactives[50].
- **Multi-fluid electrospinning:** This advanced technique allows for the simultaneous electrospinning of various solutions, enabling the blending of multiple herbal active or combination therapies into a single nanofiber system[51].

Hybrid Phyto-Nanofiber Delivery Systems

In order to enhance their therapeutic efficacy, herbal bioactives are integrated into polymeric nanofiber matrices in hybrid phyto-nanofiber delivery systems. The nanofiber network serves as a shield in these systems, stabilizing sensitive phytochemicals and improving their retention at the intended location[52]. Better medication distribution, enhanced solubility, and extended-release profiles are made possible by the combination of herbal ingredients and nanofibers. For localized and sustained delivery applications, such as wound healing and dermal therapy, where maintaining constant therapeutic levels of herbal bioactives is important for successful treatment, these hybrid systems are especially effective[53].

Use of hybrid system

- **Improved solubility and dissolution:** Herbal bioactives that are poorly soluble in water are made more soluble by hybrid phyto-nanofiber systems, which improve absorption and therapeutic efficacy.
- **Enhanced stability:** Sensitive herbal ingredients are shielded from breakdown by light, heat, and environmental elements by the nanofiber matrix.

- **Sustained and controlled release:** Hybrid systems maintain effective therapeutic doses by enabling progressive medication release over time.
- **Localized therapy:** They minimize systemic exposure by delivering herbal bioactives straight to the intended location.
- **Reduced dose and dosing frequency:** By reducing the need for frequent doses, sustained release increases patient compliance[54].

Mechanism of action

The herbal bioactive is either distributed throughout or enclosed in the nanofiber matrix in hybrid phyto-nanofiber delivery systems. The herbal substance is protected from biological and environmental damage by the nanofiber structure. Following application, the medication is gradually and carefully removed from the nanofibers, mostly by diffusion or slow polymer erosion. By maintaining steady medication levels at the target site for a longer period of time, this method enhances therapeutic efficacy and reduces the need for frequent doses[55].

Types of hybrid nanofibers

- **Herbal extract–loaded nanofibers:**This kind involves evenly mixing polymer solutions with herbal extracts just before electrospinning. They can be used for either immediate or moderate medication release and are easy to make.
- **Core–shell nanofibers:**These nanofibers have a polymer shell on their outer layer and the herbal bioactive in the center. Sensitive herbal ingredients are shielded by this structure, which also offers controlled and prolonged release[56].
- **Nanoparticle-loaded nanofibers:**herbal bioactives are absorbed into nanofibers after first being transformed into nanoparticles. Stability, drug loading, and extended therapeutic action are all enhanced by this method.
- **Multi-drug hybrid nanofibers:**Combination therapy and improved therapeutic efficacy are made possible by these systems, which contain multiple herbal or herbal-synthetic drugs[57].

Preparation Methods of Hybrid Phyto-Nanofibers

- **Direct Blending Method:** In the direct blending procedure, the polymer and herbal extract are first dissolved or dispersed in a compatible solvent. The herbal bioactive is then generated into nanofibers from this homogenous solution. For herbal substances that are stable under electrospinning conditions, this easy and popular approach is effective. It is frequently utilized for either immediate or possibly prolonged medication release and provides uniform drug distribution inside the nanofiber matrix[58].
- **Coaxial Electrospinning:** The latest technology for creating core-shell structured nanofibers is coaxial electrospinning. Using this technique, the polymer creates an outer shell and the herbal bioactive is positioned in the center. Sensitive herbal chemicals are better shielded from environmental damage by this structure. It is perfect for long-term and localized therapy because it minimizes the first burst effect and helps achieve sustained medication release[59].
- **Post-Loading Method:** Nanofibers are initially made without the herbal medication in the post-loading process. Following manufacture, adsorption or surface coating is used to load the herbal bioactive onto the nanofibers. This method works well for herbal chemicals that are dependent on electricity or heat. It prevents the breakdown of sensitive phytochemicals even though medication loading could be lower than with blending techniques[60].
- **Characterization Methods:** To assess the performance and quality of hybrid phyto-nanofibers, characterization is crucial. Fiber diameter and shape are investigated using scanning electron microscopy (SEM). FTIR, or Fourier transform infrared spectroscopy, assists in verifying drug-polymer compatibility. The drug's physical condition can be detected using X-ray diffraction (XRD) and differential scanning calorimetry (DSC). Tensile testing measures mechanical strength and flexibility, however in vitro drug release tests evaluate release behavior[61].

Mechanisms of Drug Release

To achieve targeted and prolonged therapeutic activity in hybrid phyto-nanofiber delivery systems, the drug release mechanism is essential. Polymer type, fiber diameter, porosity, hydrophilicity, and the drug-polymer matrix interaction are some of the variables that affect the release behavior of herbal bioactives. Nanofibers can be made to distribute herbal substances in a regulated and effective way by carefully combining these characteristics[62].

- **Diffusion-Controlled Release:** The herbal bioactive has an even distribution throughout the nanofiber matrix during diffusion-controlled release. The medicine quickly diffuses via the small openings in the fiber structure when the nanofibers come into touch with bodily fluids. Polymer degradation is not necessary for this process, which is powered by concentration gradients. Dense nanofiber sheets frequently exhibit diffusion-controlled release, which is appropriate for sustaining constant medication levels over time[63].
- **Swelling-Controlled Release:** The majority of nanofibers made from hydrophilic polymers like PVA, gelatin, or chitosan show swelling-controlled release. These polymers absorb water and swell when they come into contact with moisture or bodily fluids. The swelling creates channels that allow the encapsulated herbal bioactive to be released gradually by increasing the distance between polymer chains. This technique is very helpful for external applications and wound healing since it allows for consistent and continuous medication release[64].
- **Erosion-Controlled Release:** When biodegradable polymers like PLA or PCL are mixed to create nanofibers, erosion-controlled release is detected. The nanofiber matrix becomes thinner as a result of these polymers' hydrolytic or enzymatic breakdown over time. The enclosed herbal bioactive is released gradually as the polymer degrades. When extended medication release is needed for long-term therapy, this mechanism is perfect[65].
- **Multi-Phase Release:** Multiple release mechanisms are combined into a single system through multi-phase release. The drug on or near the surface of the nanofibers usually causes a sudden release, which offers quick therapeutic activity. A prolonged release phase controlled by erosion, swelling, or diffusion comes next. Because it guarantees instant relief while sustaining long-term therapeutic levels, such release behavior is highly efficient and reduces the need for regular dosage[66].

Applications of Hybrid Phyto-Nanofiber Systems

A significant development in the localized and long-term distribution of herbal bioactives is the use of hybrid phyto-nanofiber delivery systems. These methods allow site-specific drug delivery with sustained therapeutic activity by merging the structural and functional benefits of nanofibers with the medicinal potential of herbal medicines[67]. Applications where it's crucial to maintain a constant medication concentration at the target site are particularly well suited for hybrid phyto-nanofibers. They are perfect for topical, mucosal, and implantable applications due to their large surface area, porous design, and capacity to regulate drug release. Wound healing, skin and transdermal therapy, dental and periodontal treatment, vaginal and rectal administration, cancer therapy, and tissue engineering have all found extensive use for these systems[68].

- **Wound Healing: -**hybrid phyto-nanofiber systems can provide a moist environment and prolonged release of herbal bioactives, they are very successful in wound healing applications. By lowering inflammation and avoiding microbial infection, herbal-loaded nanofibers containing substances like curcumin, neem, aloe vera, and Centella asiatica allow quick wound closure[69]. The herbal active ingredients are shielded by the nanofiber matrix, which also guarantees continuous contact with the wound surface. Localized administration reduces systemic side effects, and their porous nature promotes oxygen exchange and tissue repair. Because of these characteristics, phyto-nanofibers are a possible replacement for traditional wound dressings[70].
- **Dermal and Transdermal Delivery: -** Hybrid phyto-nanofiber systems provide faster skin penetration and targeted medication administration in dermal and transdermal applications. Herbal bioactives-loaded nanofiber patches attach to the skin well and deliver prolonged release directly to the application site[71]. Nanofibers' large surface area improves therapeutic efficacy by enhancing medication diffusion through the stratum corneum. This method lowers medication loss and avoids first-pass metabolism, which is advantageous for herbal

compounds used for anti-inflammatory, antibacterial, or antioxidant purposes. These devices are very helpful in the treatment of localized inflammation and chronic skin conditions[72].

- **Oral Mucosal Delivery: -** The flexibility, thin structure, and strong adherence of hybrid phyto-nanofibers to mucosal surfaces make them ideal for oral mucosal medication delivery. Herbal bioactives can be directly absorbed into the systemic circulation when nanofiber mats are placed to the buccal or sublingual area[73]. This method works well for administering anti-inflammatory herbal medications and local painkillers. Long-term therapeutic levels are maintained through sustained release from nanofibers, which prevents first-pass metabolism and gastrointestinal breakdown. This increases patient comfort and compliance while also improving bioavailability[74].
- **Dental and Periodontal Therapy: -** By gradually releasing herbal bioactives within periodontal pockets, hybrid phyto-nanofiber systems offer effective targeted treatment in dental and periodontal therapy. Antimicrobial and anti-inflammatory substances found in herbal-loaded nanofibers help in tissue repair, gum inflammation reduction, and infection management[75]. Easy placement and extended retention at the treatment site are made possible by their fibrous composition. Sustained release enhances therapeutic results and reduces the need for constant treatment. These devices are especially helpful in treating chronic periodontal diseases, because long-term effectiveness depends on maintaining constant medication levels locally[76].
- **Vaginal and Rectal Delivery: -**hybrid phyto-nanofibers can produce targeted and long-lasting therapeutic activity; they are showing interest as vaginal and rectal drug delivery methods. To treat local infections while reducing systemic exposure, herbal bioactives with antibacterial or anti-inflammatory qualities can be added to nanofibers[77]. Good mucosal adherence and patient comfort are guaranteed by the soft and flexible nature of nanofibers. Sustained release lowers the frequency of doses by maintaining effective medication concentrations over extended periods of time. When regulated and gentle medication distribution is needed for sensitive mucosal tissues, this method is especially helpful[78].
- **Cancer Therapy: -** Hybrid phyto-nanofiber systems are being investigated for the localized administration of herbal anticancer drugs like quercetin and curcumin in cancer treatment. These techniques ensure high local medication concentration while lowering systemic toxicity by enabling direct injection or placement close to tumor locations[79]. Herbal bioactives are shielded from degradation by the nanofiber matrix, which additionally allows prolonged release. This specific approach minimizes adverse effects from traditional chemotherapy, decreases harm to healthy tissues, and improves anticancer activity. These systems have the potential to be helpful or different approaches to managing cancer[80].
- **Tissue Engineering: -** Because of their structural similarity to the extracellular matrix (ECM) seen in nature, hybrid phyto-nanofiber systems are crucial to tissue engineering. Cell adhesion, proliferation, and transformation are encouraged by the supportive structure that nanofibers supply[81]. Herbal bioactives have anti-inflammatory, antioxidant, or growth-promoting properties that further improve tissue regeneration. Applications for soft tissue, bone, and skin engineering use these technologies. Phyto-nanofibers are very promising for applications in regenerative medicine and healing because they provide both structural support and long-term transport of herbal chemicals[82].

Case Studies and Recent Findings

The potential of hybrid phyto-nanofiber delivery methods to solve the primary disadvantages of herbal bioactives has been shown by recent research. The integration of phytochemicals into nanofiber matrices enhances stability, release control, and therapeutic performance, as proved by case-based studies. Key recent developments documented in the literature are summarized up in the following examples[83].

- **Curcumin Nanofibers: -** The quick metabolism and poor solubility of curcumin has resulted in significant studies on curcumin-loaded nanofibers as a model system. The aqueous solubility and stability of curcumin are significantly improved when it gets absorbed into polymeric nanofibers, according to case studies[84]. Through its long-lasting anti-inflammatory and antioxidant properties, curcumin nanofiber mats accelerate tissue regeneration in wound healing models. Prolonged therapeutic effect at the wound site is ensured by the

nanofiber structure, which ensures regulated release of curcumin over a period of hours to days. These results support the efficacy of hybrid phyto-nanofibers in treating localised wounds[85].

- **Resveratrol Nanofibers: -** The capacity of resveratrol nanofibers to shield the substance from oxidation, light, and enzymatic breakdown has generated concern. Resveratrol's chemical stability is maintained, and its antioxidant activity is increased when it is encapsulated in nanofiber matrices, according to recent studies[86]. Resveratrol is continuously available at the target site due to sustained release from nanofibers, which enhances its therapeutic effectiveness. Applications involving skin and tissue, where sustained antioxidant protection is necessary, benefit significantly from such systems. These results show that nanofibers are efficient delivery systems for resveratrol and other unstable herbal bioactives[87].
- **Neem and Aloe Vera Nanofibers:** Recent investigations have demonstrated excellent antibacterial and wound-healing capabilities of nanofibers loaded with extracts from neem and aloe vera. Aloe vera improves tissue regeneration and moisture retention, whereas neem-based nanofibers have potent antibacterial action against both Gram-positive and Gram-negative bacteria[88]. These herbal actives are distributed uniformly and released continuously because of the nanofiber matrix, which improves therapeutic results. According to case studies, these systems are a good alternative for traditional herbal ointments and bandages since they lower the risk of infection and speed up healing[89].
- **Herbal Nanoparticle–Nanofiber Hybrids:** Recent research additionally highlights the creation of hybrid systems that combine nanofibers and herbal nanoparticles. These systems involve the formulation of herbal bioactives into nanoparticles, which are further integrated into nanofiber scaffolds[90]. This dual strategy combines the localised distribution and sustained release of nanofibers with the high loading and protection of nanoparticles. When compared to single-carrier systems, case studies show improved therapeutic effectiveness and better control over drug release characteristics. Such hybrid designs are a cutting-edge approach of delivering herbal bioactives precisely and sustainably[91].

Advantages of Hybrid Phyto-Nanofiber Systems

The delivery of herbal bioactives in a localised and sustained manner has been significantly enhanced by hybrid phyto-nanofiber delivery systems. These technologies successfully get over significant drawbacks such as low bioavailability, fast metabolism, instability, and poor solubility by integrating phytochemicals into a polymeric nanofiber matrix. As a protective and useful carrier, the nanofiber structure improves drug dispersion, sustains therapeutic concentration at the target location, and permits regulated release over a prolonged duration. They are extremely suitable for a range of pharmaceutical applications due to their high surface area, porous architecture, and modifiable polymer composition. All of these benefits work together to increase patient compliance, decrease systemic adverse effects, and improve treatment efficacy[92].

Key Advantages Explained

- **Improved Solubility and Dissolution:**Herbal bioactives that are poorly soluble in water show improved solubility when distributed within a nanofiber matrix, improving absorption and therapeutic effect.
- **Enhanced Stability of Herbal Actives:**The network of polymeric nanofibers shields sensitive phytochemicals from oxidation, heat, light, pH changes, and enzymatic breakdown.
- **Sustained and Controlled Drug Release:**Drug release can be precisely regulated to ensure sustained therapeutic doses by altering the kind of polymer and the shape of the fibre.
- **Localized Drug Delivery:**Herbal bioactives are delivered specifically to the place of action using nanofiber mats, patches, or implants, reducing systemic exposure and adverse effects.
- **Reduced Dose and Frequency:**Sustained release improves patient adherence by lowering the need for repeated dosage.
- **High Drug Loading Efficiency:**Both hydrophilic and hydrophobic herbal components can be effectively included due to the high surface area-to-volume ratio**.**
- **Biocompatibility and Biodegradability:**Minimal toxicity and gradual bodily breakdown are guaranteed by the use of safe, natural and synthetic polymers.

- **Versatility Across Applications:**Hybrid phyto-nanofibers can be used for tissue engineering, cancer treatment, dental treatment, wound healing, and skin and mucosal distribution[93].

Limitations and Challenges of Hybrid Phyto-Nanofiber Systems

Hybrid phyto-nanofiber delivery systems have a lot of potential for delivering herbal bioactives locally and sustainably, but before they are widely used in clinical and commercial settings, a number of restrictions and practical issues must be resolved. Formulation stability, manufacturing complexity, safety issues, and regulatory uncertainty are the primary causes of these difficulties. Translating laboratory research into actual pharmaceutical drugs requires an understanding of these concerns[94].

- **Stability Issues of Herbal Extracts:** In addition to being sensitive to light, heat, oxygen, and moisture, herbal bioactives are frequently chemically unstable. Certain phytochemicals may break down during processing or storage, even if they are integrated into nanofibers. It is still very difficult to maintain long-term stability without losing therapeutic effectiveness, particularly for complicated crude extracts[95].
- **Polymer–Drug Compatibility Problems:** Proper interaction between the herbal chemical and the polymer is essential for a successful formulation. Phase separation, decreased drug loading, poor drug distribution, or changed release behaviour can all result from incompatibility. Furthermore, medication bioactivity may be impacted by significant interactions[96].
- **Difficulty in Scaling up Electrospinning:** Although electrospinning works well in lab environments, it is technically difficult to scale up for industrial production. It takes advanced equipment and optimisation to maintain consistent fibre diameter, medication distribution, and reproducibility throughout large-scale manufacture[97].
- **Solvent Residues May Be Harmful:** Organic solvents are used in many electrospinning procedures. Remaining solvents can be harmful or irritating if they are not totally eliminated, especially in topical and mucosal applications. Therefore, creating safer solvent systems is crucial[98].
- **Lack of Regulatory Guidelines:** Specific regulatory frameworks for herbal delivery systems based on nanofibers are limited. Approval procedures get more complicated when plant extracts and nanotechnology are combined[99].
- **Limited Clinical Data:** The majority of research on hybrid phyto-nanofibers is still in the preclinical or in vitro stages. To verify safety, effectiveness, and long-term performance in humans, more clinical trials are required[100].

Future Prospective

Future localised and sustained distribution of herbal bioactives could be greatly enhanced by hybrid phyto-nanofiber systems. These systems are predicted to develop into intelligent, patient-specific treatment platforms as a result of the quick advances in materials science, nanotechnology, and digital healthcare. In the upcoming years, this technique may advance toward clinical translation in the following promising sectors.

- **Stimuli-Responsive Nanofibers (pH, Temperature, Enzyme):** Herbal bioactives are only released by stimuli-responsive nanofibers in response to particular biological or environmental stimuli. For instance, temperature-sensitive systems react to localised inflammation, whereas pH-responsive fibres can release medications in acidic wound conditions or tumour tissues. When certain enzymes are present in sick tissues, enzyme-responsive nanofibers break down. These intelligent solutions improve therapeutic efficacy, reduce needless exposure, and enable exact medication delivery. Herbal components can greatly enhance targeted and regulated distribution when used in these responsive systems[101].
- **4D-Printed Nanofiber Systems:** A more advanced version of 3D printing, 4D printing allows the material to alter shape or function over time in response to external stimuli. 4D printing may make it possible for hybrid phyto-nanofiber systems to show dynamic drug release behaviour, in which the structure changes in response to physiological conditions. For instance, a nanofiber patch's release rate may change in response to temperature or moisture. This technique presents a cutting-edge method for responsive and customised herbal medication delivery systems[102].

- **Combination Therapy (Herbal + Synthetic Drugs):** By combining synthetic medications and herbal bioactives in one matrix, hybrid nanofibers provide a great platform for combination therapy. Combining a synthetic antibiotic for wound healing with a natural anti-inflammatory drug is one example of how this approach can have synergistic therapeutic effects. The balanced release of both drugs is ensured by controlled co-delivery, which increases effectiveness while lowering toxicity. Particularly in cases of complex disorders, such integrated systems may enhance therapy results[103].
- **Personalized Medicine Patches:** A new approach to healthcare that is suited to the needs of each patient is called personalised medicine. Depending on the circumstances of each patient, hybrid phyto-nanofiber patches can be modified in terms of medication type, dosage, and release rate. Therapy can be precisely controlled by varying the medication loading, polymer composition, and fibre thickness. This method guarantees more effective treatment with fewer side effects and increases patient compliance[104].
- **Hybrid Systems for Chronic Diseases:** Long-term, carefully monitored medication treatment is necessary for chronic conditions like diabetes, arthritis, and cancer. By releasing herbal bioactives over long periods of time, hybrid phyto-nanofiber systems can minimise the need for regular dosage. Their capacity to be delivered locally reduces systemic toxicity while managing persistent infection or inflammation. They are also excellent options for long-term therapeutic care[105].
- **AI-Assisted Formulation Design:** The application of artificial intelligence (AI) in the creation of pharmacological formulations is growing. To improve nanofiber formulations, artificial intelligence (AI) technologies can examine medication interactions, polymer characteristics, and release patterns. AI can minimise trial-and-error experimentation by projecting optimal polymer combinations and processing conditions. Research on hybrid phyto-nanofibers and AI integration could accelerate formulation development and improve reproducibility, facilitating quicker clinical translation[106].

CONCLUSION

In the field of pharmaceutics, hybrid phyto-nanofiber delivery systems are a novel and promising strategy, especially for attaining localised and sustained delivery of herbal bioactives. These systems successfully overcome significant limitations such as low bioavailability, quick metabolism, instability, and poor solubility by combining natural phytochemicals with cutting-edge nanofiber technology. Nanofibers' special structural characteristics, such as their large surface area and capacity for regulated release, improve therapeutic outcomes while reducing systemic adverse effects. Their broad range of applications in tissue engineering, cancer treatment, cutaneous therapy, mucosal administration, and wound healing emphasises their adaptability even further.Even though there are still issues with clinical validation, regulatory approval, and large-scale production, these are gradually being addressed by continued research and technical developments. All things considered, hybrid phyto-nanofiber systems provide a biologically compatible and scientifically advanced platform that could greatly enhance the future research and clinical use of herbal medication therapies.

Table 1: Common Herbal Bioactives and Their Biopharmaceutical Limitations

Herbal Bioactive	Natural Source	Therapeutic Applications	Biopharmaceutical Limitation	Impact on Therapy	Relevance to Phyto-Nanofiber Systems	References
Curcumin	Curcuma longa (Turmeric)	Anti-inflammatory, antioxidant, anticancer, wound healing	Very poor aqueous solubility and rapid metabolism	Low absorption and short half-life	Nanofibers improve solubility, protect from degradation, and provide sustained localized release	[25]
Resveratrol	Grapes, berries, peanuts	Antioxidant, cardioprotective, anti-aging	Low chemical stability and light sensitivity	Loss of activity during storage and after administration	Nanofiber matrices enhance stability and control release at the target site	[26]
Quercetin	Onion, apple, green tea	Anticancer, anti-inflammatory, antiviral	Poor bioavailability and low permeability	Insufficient drug levels at the target tissue	Nanofibers enhance residence time and localized delivery	[27]
Asiaticoside	Centella asiatica	Wound healing, skin regeneration	Rapid degradation and low stability	Reduced therapeutic effectiveness	Nanofibers protect the drug and allow prolonged wound contact	[28]
Aloe vera actives	Aloe barbadensis	Wound healing, anti-inflammatory	Poor stability and rapid degradation	Inconsistent therapeutic response	Encapsulation in nanofibers improves stability and sustained action	[29]
Berberine	Berberis species	Antidiabetic, antimicrobial	Poor solubility and extensive first-pass metabolism	Very low systemic availability	Nanofibers help bypass metabolism via localized delivery	[30]

Neem bioactives	Azadirachta indica	Antimicrobial, anti-inflammatory	Variability in extract composition	Poor reproducibility and dose inconsistency	Nanofiber loading improves dose uniformity and controlled release	[31]
Reserpine (herbal alkaloid)	Rauwolfia serpentina	Antihypertensive	Narrow therapeutic window and instability	Risk of sub-therapeutic or toxic levels	Controlled release nanofibers enhance safety and efficacy	[32]

ABSTRACT

Dropouts (or high attrition) of patients in long term management of chronic diseases in Homoeopathic OPD practice have always remained problematic and unrelenting methodological challenge. The individualized homoeopathic practice (based on Dr. Samuel Hahnemann's concept of alternating action in proving) makes it even more difficult. The single medicine in unit dose may produce various paroxysms of opposing symptoms as part of primary action (depending on dose, potency, and individual susceptibility) and thus dynamics of dropout may reveal shaded interactions between therapeutic response, patient expectations, and real-world feasibility constraints. Assessment of dropout patterns, characterization of retention dynamics, and estimation of clinical outcomes in retrospective cohort of patients on unit dose homoeopathic treatment using remedies known to show alternating action in proving, prescribed according to Dr. Hahnemann's principles. A retrospective observational cohort study was conducted including 544 patients diagnosed with chronic illnesses who had received individualized homoeopathic care in unit dose with alternating action remedies. Data were collected over a period of 2 years (May 2022 – May 2024) at Department of Homoeopathy, AIIMS Raipur. All patients received unit doses from a list of 20 medicines exhibiting alternating action either in Centesimal or LM as per There indications and suitability to case. When a well-selected remedy failed to produce improvement, same remedy was repeated in the same potency or next higher, whether C or LM, following Dr. Hahnemann's

directions. Three follow ups were scheduled, without any medication at a gap of 2 weeks each. Retention rates, clinical outcomes in treatment completers, and attrition patterns were analyzed. A sensitivity analysis considering worst-case dropout (all dropouts classified as 'no improvement') was also performed. Out of 544 Served patients, 304 (56%) completed chosen follow-up period, whereas 240 (44%) were lost to follow up before completion. Among treatment completers, 212 patients (69.7%; 95% CI: 64.5%–74.9%) showed clinical improvement, 80 (26.3%) exhibited no visible change, and 12 (3.9%; 95% CI: 1.8%–6.1%) reported aggravation of symptoms. An intention-to-treat conservative estimate which assumes that no improvement took place among all dropouts yielded an improvement rate of 38.9% (95% CI: 34.8%–43.0%). Baseline characteristics have shown male predominance (57.1%), high educational ability (63% graduates or postgraduates), prevalence of upper-middle income class (60.4%), and a dominance of non-vegetarian dietary pattern (79.2%) hinting towards expectation mismatch. Although treatment completers have demonstrated substantial clinical improvement, high attrition rate also introduces substantial ambiguity in the study. This study provides real world evidence on application of Dr. Samuel Hahnemann's concept of alternating action in unit dose prescribing. It also underscores adoption of structured retention strategies while conducting future prospective research studies.

Keywords: Alternating action, Attrition bias, Homoeopathy, Unit dose, Chronic illness, Retrospective study, Real world evidence, Hahnemann, Dropout analysis

INTRODUCTION

Most usually, the chronic sicknesses demand sustained therapeutic engagement for a long period of time (over months or years) and retention itself becomes a decisive determinant of treatment success (independent of specific therapeutic modality under study) in these conditions[1]. As regards patient's adherence to the individualized homoeopathic practice with unit dose of indicated medicine having alternating action itself presents a distinctive set of challenges. One such challenge stems from improper understanding and clinical application of concept of what Dr. Samuel Hahnemann termed alternating action in proving. According to Dr. Samuel Hahnemann, alternating action in proving actually refers to paroxysms of primary effects of a medicine which contain symptoms that always oppose each other. This concept, appears to be first acknowledged, although indirectly and ambiguously in Hahnemann's earliest writings such as Fragmenta de Viribus Medicamentorum Positivis, as third type of action, besides primary and secondary[2]. Dr. Samuel Hahnemann plainly listed 20 medicines that possess this alternating action property in proving. These were mentioned in his major works – Organon of Medicine, Materia Medica Pura, and Chronic Diseases – and include: Aconitum napellus, Arnica montana, Arsenicum album, Belladonna, Bryonia alba, Chamomilla, China officinalis, Conium maculatum, Digitalis purpurea, Hyoscyamus niger, Ignatia amara, Magnesia polus ambu, Manganum aceticum, Menyanthes, Nux vomica, Phosphoric acid, Pulsatilla, Rhus toxicodendron, Spigelia, and Stannum metallicum.

When such a medicine – strictly chosen on strict homoeopathic principles – is given and no improvement is experienced, Dr. Hahnemann suggests that same medicine should be repeated in same potency or next higher, and clinical improvement is usual customary. This method applies to both acute and chronic pathological states. As mentioned in Aphorism 251 of 6th edition of Organon of Medicine, these instructions are valid for both centesimal and 50 millesimal potencies. In clinical practice, unit dose method of prescribing– marked by single administration of a remedy followed by 'wait & watch' policy– goes well with this principle. Patients who do not recover after initial dose may receive same remedy again in same potency or next higher, rather than switching to a different medicine or a higher potency of same medicine. This approach is significantly different from the daily dosing approach of prescribing. Patients who become habituated to repeated medication may perceive this 'wait & watch' policy as

therapeutic inaction finally leading to frustration or leaving of their treatment. Also, the complexity involving the reorganization when the alternating action of the remedy is at play, adds another layer of difficulty in day to day clinical practice.

Attrition in OPD setups still remains poorly addressed in most of homoeopathic literatures. Dropouts cause the statistical power to reduce (and bring in bias), particularly when choice to withdraw correlates with treatment response. Patients, who observe no improvement after medication (or worsening after the medicine), are considerably more likely to discontinue attending follow up visits than those experiencing relief. On the other hand, patients who attain rapid improvement may also stop too early (believing that further treatment is unnecessary). Both conditions produce missing data which are not likely to be 'missing completely at random' (a basic assumption underlying many standard statistical approaches). This phenomenon (known by the name of attrition bias) has received too little systematic attention in homoeopathic outcomes research. Most published studies have reported per-protocol analyses without agreeably addressing potential direction (or magnitude) of bias introduced by dropouts. Hence, the present study was designed to unmistakably examine dropout patterns in a real-world clinical setting where core therapeutic strategy has been unit dose prescriptions of one of the remedies from Dr. Hahnemann's list of 20 alternating action medicines (with repetition of same remedy in same potency or next higher) when clinically indicated. We have actually wished to draw meanings from clinical insights (while remaining crystal clear about methodological limitations) by doing quantification of attrition and conducting sensitivity analyses.

MATERIALS AND METHODS

Study Design and Study Setting: A retrospective observational cohort study was conducted (using medical records from Homoeopathic OPD) at All India Institute of Medical Sciences Raipur, India. This department mainly functions as a tertiary care unit (providing homoeopathic treatment to patients referred from primary health centers. It also caters those seeking direct consultation). Clinical data analyzed in this study were collected over 2 year period from May 2022 to May 2024. Data were extracted from electronic and paper-based clinical records maintained during above period.

Study Population: A total of 544 patients with various chronic illnesses formed analytical cohort. All patients had initiated individualized homoeopathic treatment with alternating action remedies (from a list of 20 medicines) during May 2022 – May 2024 period.

Inclusion Criteria: following criteria were applied for inclusion:

Diagnosis of a chronic condition lasting at least 3 months prior to enrollment, as defined by standard clinical criteria for each disease. Prescription of one or more of 20 remedies known to possess alternating action as listed by Dr. Hahnemann.Prescription of remedies in unit dose form (typically single dose of 30C or 200C or LM1 potency), with no repetition unless curative alternating action principle required repetition of same remedy in same potency or next higher after initial non-response).

Exclusion Criteria*:* Patients were excluded if:

- Baseline demographic or clinical data were incomplete to extent that outcome classification was impossible.
- presenting complaint was purely acute in nature (duration less than seven days) without an underlying chronic component.
- They had received concurrent treatment with other systems of medicine without documentation of such co-interventions.

Therapeutic Intervention*:* All included patients were managed according to standardized departmental protocols based on homoeopathic principles. process involved:

- Case-taking: Detailed history was taken including physical, mental, and emotional symptoms, along with modalities, causations, and concomitant complaints.

- Repertorization: Use of standard homoeopathic repertories for initial prescription (Kent, Synthesis, or Complete Repertory) to derive a shortlist of candidate remedies.
- Remedy selection: Prescription of a single, individualized remedy chosen from 20 medicines known to exhibit alternating action (Aconitum napellus, Arnica montana, Arsenicum album, Belladonna, Bryonia alba, Chamomilla, China officinalis, Conium maculatum, Digitalis purpurea, Hyoscyamus niger, Ignatia amara, Magnesia polus ambu, Manganum aceticum, Menyanthes, Nux vomica, Phosphoric acid, Pulsatilla, Rhus toxicodendron, Spigelia, Stannum metallicum).
- Unit dose administration: Each remedy was given as a single unit dose, potency was selected based on patient's sensitivity, disease intensity, and chronicity, either in LM or Centisemal[3].
- Repetition based on alternating action principle: If carefully chosen remedy failed to produce any clinical improvement after a practical waiting period (typically 2–4 weeks), same remedy in same potency or next higher was repeated, in accordance with Dr. Hahnemann's instruction[4].
- Follow up schedule: Patients were Asked to visit at intervals ranging from 2 to 4 weeks, depending on clinical stability and chronicity of their condition.

Outcome Measures: The clinical status based on ORIDL Scale[5] at final recorded follow up was the primary outcome measure which is categorized as:

- Improvement: Clearly documented lessening in frequency, intensity, or duration of primary symptoms, or improvement in quality of life measures as noted by treating physician and corroborated by patient report.
- No change: Absence of clinically meaningful change in symptom profile since baseline.
- Aggravation: Clear worsening of existing symptoms or emergence of new symptoms attributed to treatment by attending physician.

Secondary Outcomes:

- Retention rate (proportion of served patients completing scheduled follow up).
- Dropout rate (proportion lost to follow up before treatment conclusion).

Statistical Analysis: The summarization of baseline demographic and clinical characteristics was done using descriptive statistics. Categorical variables were expressed as frequencies and percentages with 95% confidence intervals (CIs) considered using Wilson score method for binomial proportions.
Retention rate was calculated as follows:
Retention= (Number of completed follow-ups / Total enrolled) ×100
Per-protocol outcome proportions were calculated among treatment completers only.

Sensitivity Analysis for Missing Data*:* In absence of outcome data for dropouts, a conservative sensitivity analysis was performed assuming worst-case scenario for treatment effectiveness: all patients lost to follow up were classified as showing 'no improvement'[6]. This gave a lower-bound estimate of overall improvement rate:
Conservative improvement= (Number of improvers among completers / Total enrolled) ×100
True overall effectiveness was assumed to lie between per-protocol estimate (69.7%) and this conservative floor estimate (38.9%).All analyses were performed using IBM SPSS Statistics version 26.0 (IBM Corp., Armonk, NY, USA) and Microsoft Excel for extra calculations. No imputation was undertaken for missing data beyond sensitivity analysis described above.

Ethical Considerations: study received due approval from Institutional Ethics Committee of AIIMS Raipur (IEC No. AIIMSRPR/2023/Homeo/112). Informed consent was eventually waived due to retrospective nature of analysis and use of de-identified clinical data.

RESULTS

Flow of participants and Retention: Out of 544 patients enrolled in treatment program, 304 (56%) completed scheduled follow ups. Remaining 240 patients (44%) were dropouts, as they failure to attend final scheduled follow

up despite at least one documented contact attempt by the investigator. Table 1 below summarizes patient disposition.

Baseline Sociodemographic and Clinical Characteristics*:* Study cohort showed certain demographic patterns clearly. Males have a slight preponderance (57.1%). Educational ability was notably high, with nearly 2/3rd of patients holding graduate or postgraduate degrees. Upper-middle income bracket (monthly household income between approximately ₹50,000 and ₹1,00,000) have accounted for about 60.4% of total sample. Dietary habits demonstrated a predominance of non-vegetarian consumption (79.2%). Table 2 below provides complete baseline profile of the patients.

Clinical Outcomes In Treatment Completers: Out of total 304 patients who remained in treatment through assigned follow up period, 212 (69.7%; 95% CI: 64.5%–74.9%) have demonstrated clinical improvement. A total of 80 patients (26.3%) have shown nil appreciable change in their symptom profile and treatment dependent aggravation was reported in 12 cases (3.9%; 95% CI: 1.8%–6.1%). These findings are presented below in Table 3.

Sensitivity Analysis Results*:* As per conservative estimate (which is calculated by assuming that all 240 dropouts experienced no improvement), an overall improvement rate of 212/544 = 38.9% (95% CI: 34.8%–43.0%) has been noted. The impact of attrition on interpretation of treatment effectiveness is highlighted by this considerable gap (30.8 % points) between these estimates. Let us suppose that if the true outcome distribution among dropouts happens to lie somewhere between best-case scenario (all experienced improvement, overall rate above 69.7%) and worst-case scenario (none improved, overall rate around 38.9%), the exact effectiveness remains uncertain without any further additional data.

DISCUSSION

Main Findings and Interpretation*:* This study is based on Dr. Samuel Hahnemann's concept of alternating action in proving of medicines. This retrospective observational study gives a systematic examination of dropout dynamics in real world homoeopathic practice. Finally, 3 main findings can be observed clearly:-

- Substantial Dropout: Out of 544 patients, almost half (44 %) discontinued the treatment before completing their designed follow up.
- Among the patients who remained in the study till end (n=304), clinical improvement was observed in approximately 7/10 patients.
- About 31 % point's wide divergence between per-protocol and conservative effectiveness estimates reveals the possible extent of uncertainty that has been introduced by the missing data.

These results which we have got are showing us a picture which is both encouraging and full of caution. In one hand, high improvement rate among completers suggests to us that for patients who bear waiting periods after unit dose prescribing and stick to principle of repeating same remedy in same potency or next higher when needed, meaningful clinical benefit is attainable. Also, low aggravation rate (3.9 %) points to us that serious adverse effects are uncommon with this approach (although retrospective design limits our ability to fully distinguish milder or transient aggravations). On the other hand, high dropout rate arises our suspicion about generalizability of completer analysis. Do all 304 patients who remained in treatment actually systematically differ from 240 who left or not? Clinical intuition and existing literature suggest to us that they probably are different. Patients who have experienced early benefit did have strong incentives to continue; on the contrary, those who have experienced no change (or worsening) had likewise strong reasons to seek alternatives (which is easily available in Tertiary Care hospital of National Importance like AIIMS Raipur). This mechanism is supposed to produce missing data (that are not missing at random but rather revealing treatment response). If this be the case, per-protocol estimate (of 69.7 %) would

exaggerate true effectiveness for average enrolled patient in the study. Expectation mismatch is what the demographic trends points towards in this study.

Hahnemann's Alternating Action in Clinical Context: The clinical approach of unit dose prescribing and repetition rules which are used by clinicians in this study have been taken directly from authentic writings of Dr. Samuel Hahnemann. As mentioned in the book Organon of Medicine, when a medicine chosen in strict homoeopathic way fails to act, it needs to be repeated i.e. repetition with same remedy in same potency or next higher. Our findings in this study point to us that this method of repeating same remedy in same potency, when clinically indicated, can produce favorable results in a good number of adherent patients. However, high dropout rate indicates that patient education and expectation about this approach may be inadequate (Expectation Mismatch). Although all the 20 medicines listed by Dr. Samuel Hahnemann as showing alternating action in proving are being used for centuries, still their specific alternating dynamics remain underexplored in modern day clinical practice and research. While our study does not scrutinize each remedy individually, by and large the positive response among completers suggests to us that this Hahnemannian approach still retains clinical credence. More future research in this direction should examine whether any of these 20 remedies are directly associated with higher dropout rates or faster response times.

Comparison with Existing Literature: In OPD management of chronic disease as there are various therapeutic modalities and settings, the reported attrition rates also vary widely[7]. Usually, chronic cases e.g. hypertension or diabetes have a dropout rates which ranges from 15-30 % per year, although this exceeding 40 % is not infrequent in underprivileged populations or complex treatment protocols. For studies in homoeopathy, reported attrition has been even higher in some studies. A systematic review of homoeopathy for chronic conditions has noted that dropout rates exceeding 50 % were reported in several prospective observational studies, mainly those conducted in public sector settings where patients have to face challenging demands of time and resources. Our finding of 44 % attrition rate, actually, is falling within upper range of formerly published figures but clearly is not an outlier. What separates this study from others is that it has an unambiguous framing of attrition as a primary analytical focus rather than a nuisance parameter to be mentioned quietly and very briefly in limitations sections.

In fact, by doing sensitivity analysis and discussing possible underlying mechanisms of dropout, we aim to shift the discussion toward more transparent handling of missing data in homoeopathic outcomes research, which is not usually done[8].

Clinical and Methodological Implications: For practicing homoeopathic physicians, these findings give numerous practical insights.

- High early dropout rate suggests that initial weeks of treatment are a vulnerable period. Adoption of proactive strategies e.g. telephone check ins between scheduled visits, patient education about anticipated timelines for response (including possibility that same remedy may need to be repeated) or other focused steps etc. might improve early retention.
- Intricacy of this alternating action principle of prescribing and repetition itself needs clearer communication to the patient. Patients should be made aware that 'no immediate change' does not necessarily always mean treatment failure; rather, it may be a sign that same remedy needs to be repeated in same potency. Physician should also evaluate patient health literacy and organizational capacity before starting this unit dose strategy with alternating action remedies.

For homoeopathic researchers, methodological implications of this study are equally important. Future prospective studies must include:

- Proper documentation of reasons for dropout through planned exit interviews
- Multiple follow up modalities (such as telephone, postal, or digital) so as to diminish missing data
- Gathering of at least some outcome data even for patients who discontinue treatment
- Declared beforehand in study protocol sensitivity analyses including multiple imputation or pattern mixture models that relax 'missing-at-random' assumptions.

Strengths and Limitations of the Study: This study beholds a number of strengths.

- Our sample size of 544 in this study is relatively big considering a homoeopathic outcomes study conducted in a single center.
- Our transparent reporting in this study, both of per-protocol and conservative estimates, allows readers to draw their own conclusions about plausible array of treatment effectiveness.
- Practical or real-world setting of the study enhances the chance of external validity as we compare it to tightly controlled efficacy trials.
- The unique therapeutic approach of unit dose prescribing and repetition rules based on Dr. Samuel Hahnemann's original writings on alternating action provides a logical theoretical framework that is most often missing in pragmatic homoeopathic studies.

However, some limitations of this study also require our careful and thorough attention, viz.:

- Retrospective design prohibited any ability to collect outcome data from dropouts or to verify reasons for discontinuation. We cannot settle on whether dropouts left because treatment failed, because they were cured, because of any logistical barrier, or because of unrelated personal reasons. Each scenario has diverse implications for bias.
- In absence of a control group for larger cohort (n=544) we cannot attribute observed improvements to homoeopathic treatment rather than to natural history, regression to mean, or placebo effects.
- Clinical improvement was assessed by treating physician who was not blinded to treatment exposure, introducing potential detection bias.
- While we limited analysis to 20 alternating action remedies, we did not analyze each remedy separately; response rates and dropout patterns may differ between remedies like Nux vomica and Pulsatilla, for instance.
- We did not assess obedience to treatment among those who remained in follow up; it is possible that some 'completers' did not in fact take their remedies as prescribed.
- Our Single center study limits the generalizability to other homoeopathic OPD settings in which we may have different patient demographics or any other prescribing styles.

Directions for Research in Future: Based on above mentioned findings, future research studies should prioritize prospective cohort designs instead of retrospective with implanted retention protocols. Thorough documentation of dropout reasons, categorized as treatment-related (like lack of efficacy, adverse effects, misunderstanding of waiting period or repetition principle), patient-related (like transportation difficulties, competing time demands, loss of motivation), or external (like change in employment, relocation, insurance changes), will facilitate more nuanced analysis of attrition mechanisms that come under play. Also, a useful next step with Dr. Samuel Hahnemann's original list of 20 medicines would be to plan in future a comparative observational study examining whether certain remedies in this list are associated with faster response times or lower dropout rates. Outcomes of such investigations may point to more precise prescribing guidelines for future clinical use. Also few pragmatic trials which compare standard follow up alone versus augmented retention strategies (like reminders, flexible scheduling, and financial incentives) may offer evidence to guide future clinical practice. Finally, exploring patient perspectives via a qualitative research on this unit dose prescribing approach and repetition of same remedy in the same potency or next higher could yield insights not usually available through quantitative methods alone.

CONCLUSION

This retrospective observational study is full of insights. The study utilizes the concept of Dr. Samuel Hahnemann's 20 alternating action remedies in proving of unit dose homoeopathy, with repetition of same remedy in same potency or next higher when clinically indicated. We have found that there has been substantial improvement among treatment completers (69.7 %) but we have also noticed a high attrition rate (44 %) which adds significant uncertainty to the study. Also with a conservative sensitivity analysis, which assumes no improvement among dropouts, we have noticed reduced overall improvement estimate to 38.9 %, which highlights a wide range of reasonable true

effects. On one side, positive outcomes among adherent patients suggest to us that potential benefit was received by those who persisted with this Hahnemannian approach of prescribing, the other side has a high dropout rate which underlines important real-world practicality constraints with this method. Prospective research studies in future may include structured retention strategies and systematic documentation of dropout reasons for better description of effectiveness of this therapeutic approach under routine clinical conditions.

ACKNOWLEDGMENTS

We authors are extremely grateful to the team of medical records department of AIIMS Raipur for facilitating to us access to data and we are also thankful to those patients whose clinical data has contributed to this study, particularly those patients who remained engaged in care despite many challenges of chronic illness. We also deeply acknowledge support staff who maintained records during May 2022 to May 2024.

ABSTRACT

A significant medicinal plant found in tropical and subtropical parts of Asia is Cordia dichotoma, often known as Sebestan plum or Lasora. Its fruits, leaves, bark, and seeds have long been utilized in Ayurvedic, Unani, and folk medicine to treat gastrointestinal problems, fevers, ulcers, and respiratory conditions. Numerous bioactive substances, including as terpenes, alkaloids, flavonoids, and phenolic acids, are found in phytochemical investigations and add to the plant's nutritional and medicinal value. With extracts showing antioxidant, anticholinesterase, anti-Alzheimer's, anti-Parkinsonian, and antidepressant activities, recent studies highlight its neuroprotective potential. Its involvement in the treatment of neurodegenerative and psychiatric illnesses is suggested by experimental models that demonstrate notable improvements in cognitive function, oxidative stress indicators, and neuronal protection.

Keywords: *Cordia dichotoma,* Phytochemicals, Neuroprotection, Alzheimer's disease, Parkinson's disease, Antioxidant, Antidepressant**.**

INTRODUCTION

Plant-based medicines are considered the first line of defense for maintaining health and preventing disease, and they remain the primary source of new pharmaceuticals with therapeutic properties [1]. Of an estimated 72,000 plant species with medicinal qualities, more than 3,000 are recognized in India [2]. The "science of life," Ayurveda, states that a person is healthy if their metabolism is balanced. Allopathy, which employs 30 plant species to treat ailments, Ayurveda (700), Amchi (600), Unani (700), and Siddha (600) are examples of indigenous medical systems [1]. *Cordia dichotoma* is one of the deciduous plants that are used for traditional medicinal purposes all over India. Polysaccharide content in the fruit has been observed to be high. A sticky, jelly-like substance is produced by ripe *C. dichotoma* fruit. Plants are used in Unani medicine as antiviral, antibacterial, and antitussive agents. The general public in India uses a lot of josandah, which are polyherbal preparations with *C. dichotoma* as the main component, to cure fevers, respiratory disorders, coughs, catarrh, and the common cold. Leaves and stem bark have been used since ancient times to cure a variety of illnesses, including gonorrhea, leprosy, fever, diarrhea, dyspepsia, and burning sensations. Plant leaves have long been used for anthelmintic, astringent, diuretic, demulcent, purgative, expectorant, tonic, ulcer, and coughing purposes. [3]

Geographical distribution:
C. dichotoma is often found in tropical and subtropical regions. It can reach elevations of up to 1500 meters in the sub-Himalayan tract and outer ranges. It is found in a wide range of forests, such as the dry deciduous forests of Rajasthan, the moist deciduous forests of the Western Ghats in India, and the tidal forests of Myanmar. In Maharashtra, it grows well in damp monsoon forests [4]. Rather than growing gregariously, it grows singly in moist, shaded slopes and ravines. The species is found throughout the Philippines and is found in low- and medium-elevation thickets and secondary woods. Furthermore, it extended to areas like southern China, Formosa, Polynesia, tropical Australia, and Peninsular Malaysia. This species is propagated through seeds. [5].

Classification:[9]
Kingdom: Plantae
Division: Magnoliophyta
Class: Dicotyledons
Subclass: Astaridae
Order: Lamiales
Family: Boraginaceae
Genus: Cordia
Species: *Cordia dichotoma* Forst.

Vernacular name:[9]
India : Gonda, lasora, leshora
Javanese : Kendal
Malaysia : Sekendal, sekendai, petekat
Thailand : Paw man
English : Sebestan plum, soap berry, fragrant manjack
Sumatran : Nunang

Local Names:[9]
English : (sebesten, clammy cherry,Indian cherry)
Bangali : (buhal, bahubara)
Hindi : (lasura, bhokar, borla)
Gujarati :(vadgundo, gunda)
Sanskrit: (bahuvarka, shleshmatak, shelu)

Javanese: (Kendal)
Lao : (sino-Tibetan) (man, man khok)
Malay: (petekat,sekendai)
Tamil : (vidi, naruli, kalvirusu)
Nepali : (kalo bohori, bohori)
Thai : (mandong, manma, phakmong)

Morphology of *C. dichotoma*:

The *Cordia dichotoma* tree is a small to medium-sized deciduous tree with a short bole, a short, crooked trunk, and a spreading crown. The simple, entire, and slightly dentate leaves are elliptical-lanceolate to broad ovate in form, with a circular, cordate base. The stem bark is either smooth and grayish brown or furrowed longitudinally [4]. Flowers are bisexual, have short stalks, form loose corymbose cymes, and vary in color from white to pink. Fruits with sticky flesh can be consumed. It's a yellow or pinkish-yellow drupe that's ovoid or globose and rests in a saucer-like, expanded calyx. The pulp becomes black and viscid as it ripens. [5].

Nutritional information:

C. dichotoma is used as food because the entire plant is edible. Moreover, young fruits are preserved and used as vegetables [4]. To protect the body from extreme heat waves, a flower and curd mixture is applied twice a day [6]. The rural inhabitants of Orissa's coastal regions eat the ripe fruits raw. The high levels of proteins and fatty oils in *C. dichotoma* seed kernels make them suitable for use as cow feed [7]. The plant's 97% polysaccharide gum is employed in a variety of pharmacological applications. The fruit's chromium contains therapeutic benefits for diabetes. Some anti-nutritional components found in fruits include oxalic acid (250 mg), phytate phosphorus (100 mg), and phytic acid (355 mg) per 100 g. The branches of the *C. dichotoma* plant were used to identify new natural cellulose textiles [8].

Phytochemical Investigation:[10]

There are pyrrolizidine alkaloids, coumarins, flavonoids, saponins, terpenes, and sterols in the fruit, leaves, and seed. A concentration of 100 μg/mL of taxifolin from *C. dichotoma* seeds shown encouraging DPPH free radical scavenging behavior. Apigenin (5 mg/kg, p.o.) from *C. dichotoma* demonstrated notable healing and a decrease in inflammatory enzymes when tested for ulcerative colitis, according to another research. It was discovered that the seeds of *C. dichotoma* contained 7.60% fatty oil, with stearic, oleic, and linoleic acids being the main components. Kaempferol, quercetin, and isorhamnetin are the three flavonoids that were separated from the butanol fraction of *C. dichotoma* fruits. From a butanol extract of *C. dichotoma* leaves, which included rosmarinic acid as a significant ingredient, six flavonol glycosides and two phenolic compounds were identified.

According to a different investigation, the ethanolic extracts included rosmarinic acid (0.0028%), amino acids (1.39%), triterpenoids (0.075%), and polyphenolic chemicals (1.0%) (Tian et al., 2014). An overview of *Cordia dichotoma's* chemical components and therapeutic applications has been provided. Here, we present the compounds that were isolated from the leaves of C. dichotoma: β-sitosteryl-3βglucopyranoside-6'-O-palmitate (1), nervonyl 4-hydroxy-transcinnamate ester (2), β-sitosterol (3), and chlorophyll a (4); and from the twigs: 3 and 1,2-dilinoleoyl-3-linolenoylglycerol (5). As far as we are aware, this is the first report on 1-2 being isolated from C. dichotoma. [10]

Neuroprotective Behaviour of *C. Dichotoma*:

Parkinsons Disease

The degeneration of dopamine-producing neurons in the substantia nigra is a hallmark of Parkinson's disease (PD), a neurological condition. Tremors, bradykinesia, abnormalities in gait, postural abnormalities, and rigidity are the outcomes of this degenerative process. It is well accepted that oxidative stress is a major factor in the susceptibility of dopaminergic neurons, even if the problem of controlling dopaminergic neuronal transmission in Parkinson's disease (PD) is still open. Furthermore, a significant amount of preclinical and clinical research has hypothesized that one

possible mechanism for the fatal effects of haloperidol is the unchecked production of reactive oxygen species (ROS) [11].

In order to evaluate the effects of haloperidol-induced Parkinson's disease in rats, the current experimental study used three behavioral assessment parameters: the Open Field Test, Akinesia (Stepping Test), and Catalepsy Test. In this work, the effects of pre-treating rats with 200 and 400 mg/kg of an ethanolic extract of *C. dichotoma* leaves as well as a standard medication called syndopa (a combination of L-dopa and carbidopa) at a dose of 10 mg/kg were examined. The course of therapy was given for seven days. The findings indicated a substantial decrease ($p < 0.001$) in the cataleptic score and a rise ($p < 0.001$) in a variety of behavioral indicators, including ambulation, activity in the center square, raising, grooming, and the number of steps taken.

These effects were consistently seen over the course of the observation period when compared to animals who received haloperidol treatment. The test drug was administered at 200 and 400 mg/kg, while syndopa was administered at 10 mg/kg. The neuromuscular strength improved in a highly significant ($p < 0.001$) way. When rats were given 400 mg/kg of an extract of *C. dichotoma* leaves, the neuroprotective effects were greatest. It was discovered that these effects were similar to those of the syndopa-treated group. [13]. Rats in the haloperidol group had lower levels of Catalase and higher levels of MDA, indicating oxidative stress in the brain. MDA was decreased and catalase was elevated by syndopa and test medication in comparison to rats treated with haloperidol ($p < 0.001$). Dopamine levels were decreased and protein concentrations were increased by daily haloperidol dosage. The administration of syndopa and test medications increased blood dopamine levels and lowered protein levels in comparison to haloperidol therapy ($p < 0.001$).

The brain histopathology of the test drug-treated and syndopa groups revealed intact neuronal cells, whereas the group treated with haloperidol had apoptosis and inflammation, which resulted in neuronal damage. Resistance to oxidative stress is provided by C. dichotoma. Numerous investigations have demonstrated that *C. dichotoma* possesses antioxidant properties [12]. It's possible that antioxidants shield PD neurons from intracellular ROS production. Therefore, antioxidants may protect neuron workouts and aid in the treatment of Parkinson's disease. The aforementioned behavioral and neurochemical characteristics of *C. dichotoma* suggest that it may alleviate Parkinson's disease symptoms by influencing the antioxidant system and reestablishing dopamine. Consequently, *C. dichotoma* could be useful as a preventative therapy for Parkinson's disease.

Similar to syndopa, the ethanolic extract of *C. dichotoma* leaves protected against Parkinson's disease caused by haloperidol. According to our research, *Cordia dichotoma* G. Forst. may help prevent and lessen extrapyramidal side effects from clinically prescribed antipsychotic drugs. The substance could be used as a natural remedy for the side effects of haloperidol. The neuroprotective effect that the extract from *C. dichotoma* leaves showed in this study necessitates more investigation into its molecular mechanism and its therapeutic implications. [13]

Alzheimer's Disease

Phenolic chemicals have considerable antioxidant capacity, which can have a very positive impact on health [14]. Recent studies have demonstrated that flavonoids, phenolic acids, and their derivatives prevent or postpone neurodegenerative diseases and markedly enhance cognitive performance. Inhibition of ChEs, Aβ formation, and signaling pathway modulation were their mechanisms. The most widely used and practical technique for figuring out the TPC in plants is the Folin-Ciocalteu test, which has high consistency. Certain redox reagents called Folin Ciocalteu reagents combine with polyphenols found in plant extracts to create a blue color complex that can be detected using visible light spectrophotometry. 137.9±6.76 and 87.94±4.41 μg GAE/1 mg sample, respectively, were the TPCs found in CDLME and CSLME in this investigation. There are many popular spectrophotometric methods that exploit the production of aluminum complexes to measure the TFC in medicinal plant samples. The TFC in CDLME was 22.44±1.21 μg RE/1 mg sample, while in CSLME it was 18.25±1.75 μg RE/1 mg sample. The TFC in *C. dichotoma* leaves was 160 mg quercetin E/g extract, according to earlier reports [15]. It was determined from the data

that flavonoids make up a small percentage of the total phenolics in both plants. More TPC and TFC are also present in CDLME than in CSLME.

Among these, HPLC has been the most widely used method for rapidly determining the bioactive ingredients of extracts from medicinal plants because it enables thorough profiling of intricate plant samples [16]. Therefore, phytochemical study was conducted using HPLC-fingerprint analysis on the aforementioned crude extracts in an effort to determine their phytoconstituents and create associations between the chemical components and the ChEs inhibitory efficacy. The presence of eleven phenolic compounds was detected by HPLC-fingerprint analysis of CDLME. In this regard, leaves of *C. dichotoma* have been shown to contain rutin, kaempferol, rosmarinic acid, chlorogenic acid, and gallic acid. However, instead of the leaves, other portions of the plant were found to contain p-coumaric acid and ferulic acid [17].

To our knowledge, this is the first time that dihydrokaempferol and chrysin have been identified in *C. dichotoma* leaves. The HPLC fingerprint study of CSLME only identified five phenolic chemicals. In our research, we found dihydrokaempferol, chlorogenic acid, and rosmarinic acid in C. sebestena leaves for the first time. Nevertheless, the fruit of C. sebestena was previously used to separate rosmarinic acid and its methyl ester. Very high quantities of rosmarinic acid were found in both species, which is consistent with earlier findings that rosmarinic acid is prevalent in Boraginaceae species. About 50 million people worldwide suffer from AD at the moment, and by 2050, that figure is expected to quadruple.

Plants are the subject of extensive research in an effort to identify potential therapeutic components that may be applied to the treatment of neurological disorders [18]. Cholinergic and cognitive functioning have been demonstrated to be enhanced by the in vivo and in vitro ChEs inhibitory actions of conventionally used herbal medicines. AChE and BChE are the primary enzymes involved in the degradation of ACh and butyrylcholine, and their inhibition is crucial. A number of clinical trials have demonstrated the several therapeutic benefits of ChEs inhibitors, including antioxidant activity, modulation of amyloid precursor protein processing, and inhibition of Aβgenesis. AChE inhibitors increase the quantity of ACh at the synapse, allowing the signal to be amplified, and enhance both cognitive performance and everyday life results [19].

The primary focus of the current investigation is the crude extracts of *C. dichotoma* and C. sebestena, as well as their subsequent fractions, and their in vitro ChEs inhibitory effects. IC50 values for CDLME and CSLME in AChE inhibitory tests were 38.76 ± 0.44 and 50.79 ± 4.18 μg/ml, respectively. Many herbs used in traditional medicine have been investigated for their ability to enhance memory, but only a small number of them have demonstrated a sufficient level of AChE inhibitory efficacy [19]. The crude extract from *C. dichotoma* appeared to be a more potent AChE inhibitor than other plants. As evidenced by their lowest IC50 values, CDLEF and CSLME showed the best polarity of the active compounds and the best inhibition of the enzyme. [20]

Given that its levels and activity notably increase in the later stages of AD, BChE is yet another drug target for the disease. Early studies focused mostly on AChE, but dual inhibitors of AChE and BChE, such rivastigmine, are now thought to have more sustained activity throughout AD and may help delay the disease's development. CDLME and CSLME were found to exhibit BChE inhibition in these studies, with respective IC50 values of 50.79 ± 4.18 and 52.71 ± 0.48 μg/mL. This finding implies that there is good BChE inhibitory activity in the two plant crude extracts.

In order to establish the polarity of the active compounds, CDLEF and CSLEF had the lowest IC50 values. In two enzyme assays (AChE and BChE assays), the hexane fraction of both plants showed the worst inhibition of both enzymes, as indicated by the highest IC50 values. These results made it evident that the crude extract of *C. dichotoma* leaves had more inhibitory action for AChE and BChE than the crude extract of C. sebestena leaves, which may be related to the higher TFC and TPC in the former. Furthermore, compared to C. sebestena fractions, all investigated fractions of *C. dichotoma* exhibited greater AChE and BChE inhibitory activity" The two plants' HPLC analyses revealed the presence of a variety of phenolic chemicals, each of which has been shown to have strong anti-AD

properties through various pathways. More specifically, in rats with aluminum chloride AD, p-coumaric acid restored hippocampus synaptic plasticity impairment and reduced memory impairments.

In AD caused by scopolamine, rosmarinic acid and chlorogenic acid boosted cholinergic signal transduction, raised the quantity of ACh in the brain, and exacerbated the short-term memory loss. A research found that rutin decreased the cytotoxic effects of tau oligomers in a mouse model of AD and shielded neuronal architecture from them. In several rat models, chyrsin, ferulic acid, and kaempferol have neuroprotective benefits by lowering oxidative stress, inflammation, apoptosis, and amyloidosis. Cinnamic acid enhances lysosomal biogenesis and reduces Aβ in an AD mouse model by activating PPARα" Previous studies have demonstrated the ChEs activity of phenolic compounds, which is in line with our current investigation. In vitro AChE and BChE inhibitors that work well include rutin, kaempferol, chyrsin, rosmarinic acid, ferulic acid, and P-coumaric acid. AChE inhibition was discovered by chlorogenic acid. [21]

Based on the above findings, Rashno M etal (2022) deduce that the neuroprotective qualities of the discovered phytochemicals may have been influenced by the anti-ChEs in crude extracts. An evidence-based foundation for further research and the separation of bioactive phytoconstituents for clinical trials is provided by this study. The presence of important phenolic compounds with neuroprotective qualities was shown by phytochemical study of CDLME and CSLME. For the first time, dihydrokaempferol and chrysin were identified in *C. dichotoma* leaves by HPLC analysis, whereas *C. sebestena* leaves included rosmarinic acid, chlorogenic acid, and dihydrokaempferol.

Hussein HM, et al. (2024) showed that the crude methanolic extracts of *C. dichotoma* and C. sebestena, as well as their polar fractions, exhibit significant ChEs inhibitory activity, which might be helpful in the treatment of AD. The ChEs inhibitory activity of *C. dichotoma* was greater than that of C. sebestena. Studies using molecular simulations on the substances that were found to contain these enzymes validated the results. As for the AChE and BChE targets, the most promising ones were rutin, chlorogenic acid, and rosmarinic acid, with binding scores of -8.91 and -22.37, -7.66 and -11.51, and -7.89 and -8.99 kcal/mol, respectively. We are aware that this is the first study to examine the phenolic profile of C. sebestena and the inhibition of cholinesterase by *C. dichotoma* and C. sebestena. [20].

Antidepressant Activity

By examining its effects on alterations in depression-like behaviors and the associated neurotransmitters in a chronic unpredictable moderate stress rat model of depression, this study seeks to determine the antidepressant effects of the aqueous extract of *C. dichotoma* fruits. We used high-performance liquid chromatography to measure rosmarinic acid. The rats treated with the aqueous extract for chronic unpredictable mild stress exhibited typical anti-depressive-like behavior, such as a significant increase in sucrose consumption in the sucrose preference test, a significant decrease in immobility time in both the forced swimming test and the open field test, and an increase in swimming time in the forced swimming test.

Additionally, LC-MS/MS analysis revealed that the treated rats' frontal cortex, amygdala, hippocampus, and striatum tissue had a considerably lower serotonin turnover rate (5-HIAA/5-HT). Through the inhibition of monoamine oxidase by rosmarinic acid, the work offers the first in vivo evidence of potential pathways for modifying anti-depressive-like effect by controlling the turnover rate of serotoninergic neurotransmitters. These results offer fresh and convincing proof of a new use of the fruits of the medicinal plant *C. dichotoma* in the treatment of depression and might pave the way for the creation of innovative plant-based antidepressants..[24]

CONCLUSION

Cordia dichotoma is a traditionally important medicinal plant with rich phytochemical diversity, including flavonoids, phenolic acids, alkaloids, and terpenoids that contribute to its wide range of pharmacological actions. Experimental studies have demonstrated its significant antioxidant, anti-inflammatory, anticholinesterase, and neuroprotective

effects, supporting its potential role in managing neurodegenerative disorders like Alzheimer's and Parkinson's diseases. The plant's extracts have shown the ability to enhance memory, reduce oxidative stress, and protect neuronal cells from degeneration, while also exhibiting antidepressant activity through serotonergic modulation. These findings validate its long-standing use in traditional medicine and highlight its potential as a natural source for developing plant-based neuroprotective and psychotropic drugs. However, further research including molecular, toxicological, and clinical studies is essential to establish its safety, efficacy, and mechanisms of action for therapeutic applications.

Table No. 1 Nutritional value of leaves, seed kernels and fruits of *C. dichotoma*:[8]

Plant Part	Nutrient	Value
Leaves	Crude Protein	12% – 15%
	Crude Fiber	16% – 27%
	Nitrogen-Free Extract (NFE)	42% – 53%
	Ether Extract	2% – 3%
	Total Ash	13% – 17%
	Total Calcium	2% – 4%
	Phosphorus	0.3%
Seed Kernels	Water	32 g per 100 g
	Fatty Oils	46%
	Proteins	31%
Fruits *(per 100 g pulp)*	Pulp Content	70% of fruit
	Water	6 g
	Proteins	35 g
	Fats	37 g
	Carbohydrates	18 g
	Calcium (Ca)	55 mg
	Phosphorus (P)	275 mg
	Zinc (Zn)	2 mg
	Iron (Fe)	6 mg
	Manganese (Mn)	2 mg
	Chromium (Cr)	0.2 mg
	Copper (Cu)	1.6 mg

Table No.02: Pharmacological Activities of *C. Dichotoma*:

Sr. No.	Activity	Part Used	Proposed Mechanism of Action (MOA)	Reference
1.	Cognitive enhancement (scopolamine model)(22)	Fruit methanol extract	Restores hippocampal AChE, acetylcholine, noradrenaline, dopamine; antioxidant + anti-AChE activity	Hussein HM et al.. (2024)
2.	Anti-Alzheimer's type dementia (scopolamine mice) (23)	Leaves methanol extract	Enhances cholinergic system, increases SOD/GSH, reduces AChE & nitrites, protects hippocampal neurons	Singh et al.(2023).
3.	Neuroprotection in Parkinsonism (haloperidol model)(13)	Leaf/bark extract	↓ MDA, ↑ catalase/SOD; reduces akinesia and catatonia; histological protection of cortex, hippocampus, substantia nigra	Keserla B et al. (2023)
4.	Anticholinesterase activity (20)	Leaves (methanol extract, ethyl acetate fraction)	Inhibits AChE and BChE; phenolic compounds rosmarinic acid, rutin binding to enzymes via docking	EI-Kashoury M et al. (2024)
5.	Antioxidant-mediated neuroprotection (4)	Bark extract	Increases enzymatic antioxidants and DPPH scavenging to reduce oxidative stress injury in neural tissue	Hussain N et al. (2020)
6.	Depression-like behavior alleviation (24)	Fruit aqueous extract	Modulates serotonergic neurotransmitters; reduces immobility in forced swim and tail suspension tests	Li et al. (2023)
7.	Neuroinflammation reduction (23)	Bark/leaves	↓ brain nitrite and inflammatory markers in Alzheimer's model	Singh et al. (2023)
8.	Oxidative stress mitigation (13)	Leaf/bark extracts	↑ SOD and GSH, ↓ MDA in haloperidol & scopolamine models	Keserla B et al. (2023)

ABSTRACT

Short Video applications such as Instagram Reels, Facebook reels, YouTube shorts and other similar applications have become increasingly popular among university students. Excessive use of these platforms has been associated with behavioural, cognitive and psychological effects. This Narrative Review aimed to synthesize available literature regarding the relationship between short-form video application use and sleep quality, concentration, and professional behaviour among health science students. Literature published between 2023 and 2026 was reviewed from databases including Pub Med, Google Scholar, Frontiers and BMC Psychology. Terms such as short-form video applications and sleep quality, short-form video and concentration and short-form video application and professional behaviour were used during search process. Boolean operators like AND and OR were also applied to obtain more relevant and focused studies. The selected literatures were critically analysed and synthesized narratively according to SANRA recommendations for narrative review articles. The Reviewed studies consistently demonstrated that excessive short-form video use is associated with poor sleep quality, reduced concentration, decreased attention span, academic procrastination, and altered behavioural

outcomes. Existing evidence suggests the need for awareness regarding responsible digital media use among students.

Keywords: Short-form video application, Sleep quality, Concentration, Professional Behaviour, Health Science Students

INTRODUCTION

The use of short-form video application has increased rapidly among adolescents and university students in recent years because of the widespread availability of smart phones and internet services. Platforms such as Instagram reels YouTube Shorts and Moj have become highly popular among young adults due to their engaging and easily accessible content. Short-form video applications have transformed the digital media landscape among young adults[1]. Platforms such as Instagram Reels and YouTube Shorts provide highly engaging content that encourages prolonged screen exposures[2]. Health science students are particularly vulnerable because of academic stress, irregular schedules and extensive smart phone use[8]. Recent evidence suggests that excessive short-form video use negatively affects sleep quality, attention span, concentration and behavioural outcomes[5]. Studies also indicate that addictive scrolling behaviour contributes to procrastination, cognitive fatigue and reduced professional effectiveness[10,21,25]. Therefore, understanding the relationship between short-form video application use, sleep quality, concentration and professional behaviour is important among health science students.

Data Resources

The literature for present narrative review was obtained from electronic databases and scholarly search engines including Pub Med, Google Scholar, Frontiers, Cureus, BMC Psychology and Semantic Scholar. Relevant peer-reviewed studies published between 2023 and 2026 were reviewed. The literature for the present review was searched using different keywords related to short-form video applications and their effects on students. Terms such as short-form video applications and sleep quality, short-form video and concentration and short-form video application and professional behaviour were used during search process. Boolean operators like AND and OR were also applied to obtain more relevant and focused studies. The selected literatures were critically analysed and synthesized narratively according to SANRA recommendations for narrative review articles.

METHODOLOGY

The present study adopted a narrative review design to synthesize available literature regarding the relationship between short-form video application use, sleep quality, concentration, and professional behaviour among health science students. The review was prepared according to SANRA recommendations for narrative review articles. Relevant literature published between 2023 and 2026 was searched from electronic databases including Pub Med, Google Scholar, Frontiers, Cureus, BMC Psychology, IEEE Xplore and Semantic Scholar. Studies focusing on adolescents, university students, young adults and health science students were included in the review. Cross-sectional studies, descriptive studies, correlational studies, experimental studies, randomized controlled trials, and systematic reviews relevant to the topic were considered. Articles unrelated to short-form video applications, duplicate studies, and non - English publications were excluded. The selected studies were critically analysed, compared and synthesized narratively to identify major themes and relationships related to sleep quality, concentration and professional behaviour associated with short-form application use.

RESULTS

Short-Form Video use and Sleep Quality

Several studies reported a significant association between excessive short-form video use and poor sleep quality among university students. According to Jia and Wang, Results shows that low self-control and habitual short-form video use increased poor sleep outcomes among college students[1]. Mohammed et. al found that medical students using short-form videos for more than 1 hour daily experienced lower concentration and poor sleep quality[2]. Jiang and Yoo also reported a strong relationship between short-form video addiction, social anxiety, and poor sleep quality among adolescent in china[8]. Zhao and Kou found that short-video addiction was positively associated with sleep problems and procrastination among college students[9].

Short-Form Video Use and Concentration

Multiple studies identified reduced attention span and poor concentration among heavy users of short-form video applications. Joseph et.al. found that heavy users demonstrated significantly reduced attention span and poor time management skills[12]. Lin et.al. reported that continuous consumption of short-video negatively affected sustained attention[16]. Gong and Tao observed that higher levels of short-video usage were associated with lower attention scores and reduced academic performance among school students[18]. Malhotra and Patnaik also found that reduced concentration and cognitive abilities among university students using short-form video application excessively[19].

Short-Form Video use and Professional Behaviour

Some evidence suggests that excessive short-form video use may affect the professional behaviour and decision-making. Zhang and Li identified that students with higher short-video addiction demonstrated greater impulsive and risk-taking behaviour[21]. Lin st.al. found that excessive short-video addiction negatively affected creative self-efficacy and carrier interests among students[25]. Another studies also shows regarding self-regulation and professional effectiveness among frequent users of short-video platforms[22,24].

DISCUSSION

The literature review shows that consistent evidence regarding the negative effects of excessive short-form video application use on sleep quality, concentration, and professional behavioural outcomes. Most studies demonstrated that prolonged scrolling behaviour and rapidly changing digital content may impair sustained attention, emotional regulation, and productivity[1,2]. The findings also suggests that health science students may be particularly vulnerable because of their demanding academic and clinical responsibilities. The findings of present review suggest that prolonged use of short-form video applications may affect sleep quality among students. Many students spend long hours watching videos during night-time, which may delay sleeping habits and reduce sleeping duration[26]. Health science students require adequate sleep for effective learning, memory, concentration and clinical performance. Therefore, disturbed sleep may affect both educational and professional devdelopment[27]. The review also indicates that excessive exposure to short-form videos may negatively influence concentration and attention span. Short-form videos usually contain rapidly changing visual and audio content that may reduce the ability to focus on one activity for a longer period[28]. Health science students are expected to maintain discipline, responsibility, communication skills, ethical behaviour, and emotional control during their academic and clinical treaining[29]. Some students may also develop difficulty in balancing academic responsibilities with social media use[30]. Overall, the present review suggests that excessive use of short-form video applications may negatively affects sleep quality, concentration, and professional behaviour among health science students. Promoting responsible digital media use and creating awareness regarding healthy screen habits may help reduce these negative effects.

ACKNOWLEDGEMENT

We acknowledge the professional support and guidance received from the editorial committee in manuscript preparation, review, approval, and data analysis during the completion of this narrative review. We also express sincere gratitude to all faculty members, mentors, and researchers whose valuable suggestions and scholarly contributions supported the successful completion of the study.

CONCLUSION

The present narrative review identified a significant relationship between short-form video use and adverse outcomes related to sleep quality, concentration and professional behaviour among students. Existing evidence supports the need for awareness programs promoting responsible digital media use and further research among health science students.

ABSTRACT

Class III malocclusion is a complex dentofacial condition characterized by diverse skeletal and dentoalveolar components and variable growth patterns. Contemporary management strategies have evolved considerably with advancements in diagnostic technologies, growth assessment, biomechanics, and digital workflows. Accurate diagnosis and growth evaluation remain fundamental to treatment planning, guiding the selection of growth modification, orthodontic camouflage, or surgical intervention. Recent evidence suggests that skeletal anchorage–assisted orthopedic approaches provide superior skeletal outcomes compared to conventional facemask therapy, while orthodontic camouflage remains effective in carefully selected mild to moderate cases. For severe skeletal discrepancies, orthognathic surgery continues to be the definitive treatment, with increasing emphasis on bimaxillary procedures, airway preservation, and virtual surgical planning. Digital orthodontics, including three-dimensional imaging and artificial intelligence, has further enhanced diagnostic precision and treatment predictability; however, concerns regarding long-term evidence and ethical considerations persist. Long-term stability remains a challenge and is influenced by growth pattern, treatment modality, and patient compliance. This review critically evaluates current evidence and highlights a decision-based, individualized approach for optimizing functional and esthetic outcomes in the management of Class III malocclusion.

Keywords: Class III malocclusion, orthodontic camouflage, 3D imaging, digital orthodontics, artificial intelligence

INTRODUCTION

Class III malocclusion is a complex dentofacial deformity characterized by maxillary deficiency, mandibular prognathism, or a combination of both, often accompanied by transverse and vertical skeletal discrepancies[1]. Its multifactorial etiology is predominantly influenced by genetic factors, with environmental and functional components contributing to clinical variability. Early diagnosis is critical, as craniofacial growth patterns strongly affect treatment timing, outcomes, and long-term stability[2]. Advancements in diagnostic modalities, particularly cone-beam computed tomography and three-dimensional facial analysis, have enhanced the accuracy of skeletal assessment and growth prediction, allowing for more individualized treatment planning[3]. The introduction of skeletal anchorage systems, including temporary anchorage devices and miniplates, has expanded orthopedic treatment possibilities beyond the early mixed dentition stage[4]. On the other hand, orthognathic surgery remains the gold standard for managing severe skeletal Class III malocclusion, especially when facial esthetics, occlusal correction, and airway considerations are priorities. Contemporary surgical approaches emphasize minimally invasive techniques, rigid fixation, and virtual surgical planning to improve precision, reduce morbidity, and enhance postoperative stability[5]. Given ongoing advancements in diagnostic technologies, biomechanical principles, and treatment modalities, a focused review of current trends in the management of Class III malocclusion is timely and essential[6-7]. This review aims to critically analyze recent advances in orthopedic, orthodontic, and surgical management strategies, emphasizing evidence-based decision-making and future directions in treatment.

METHODOLOGY

This narrative review was conducted to synthesize and critically evaluate current evidence on the management of Class III malocclusion, with emphasis on recent advances in diagnosis, growth modification, orthodontic camouflage, surgical management, and digital orthodontics. A comprehensive literature search was performed using electronic databases including PubMed, Scopus, Web of Science, and Google Scholar**.** The literature search was limited to studies published between 2000 and 2025**,** with particular emphasis on recent high-quality publications from 2020 to 2025 to ensure inclusion of contemporary evidence. Eligible studies included systematic reviews, meta-analyses, randomized controlled trials, and well-designedobservational studies**.** Relevant narrative reviews were also included where appropriate. Case reports, editorials, and non-English publications were excluded unless they provided significant clinical insights. Articles were initially screened based on titles and abstracts, followed by full-text assessment for eligibility. Preference was given to studies with higher levels of evidence. Data from selected studies were synthesized descriptively, with emphasis on comparative evaluation of treatment modalities, clinical applicability, and long-term outcomes. This review did not involve human participants or patient data, so, therefore, ethical approval was not required**.**

Etiology and Growth Pattern of Class III Malocclusion

The etiology of Class III malocclusion is complex and multi factorial, resulting from interactions among genetic, epigenetic, environmental, and functional factors during craniofacial growth[8]. Genetic influence is the primary determinant, particularly in mandibular prognathism, as supported by family, twin, and genome-wide association studies. Despite strong heritability, phenotypic expression varies considerably, indicating the modifying role of non-genetic factors[9].Maxillary deficiency is a major but often under diagnosed component, with three-dimensional imaging demonstrating that maxillary retrusion contributes more frequently to Class III malocclusion than true mandibular excess. Environmental and functional influences, including airway obstruction, mouth breathing, altered tongue posture, and neuromuscular imbalance, further affect skeletal development[10].

Longitudinal studies reveal prolonged and excessive mandibular growth in Class III individuals, often extending beyond puberty and increasing relapse risk. Growth direction, skeletal maturation timing, and sex-related differences significantly influence severity and treatment response[11]. Advances in three-dimensional imaging, superimposition

techniques, and emerging artificial intelligence–based growth prediction models have improved understanding of growth behaviour. Comprehensive knowledge of etiologic factors and growth patterns is essential for accurate diagnosis, optimal timing, and individualized management of Class III malocclusion[3].

Diagnostic Advances and Three-Dimensional Imaging in Class Iii Malocclusion

Accurate diagnosis is essential for effective management of Class III malocclusion, as successful treatment depends on precise identification of skeletal, dentoalveolar, and functional components. Conventional two-dimensional cephalometric analysis, while informative, is limited by magnification errors, structural superimposition, and inadequate assessment of transverse and asymmetric discrepancies commonly seen in Class III cases[12]. The introduction of cone-beam computed tomography has markedly improved diagnostic accuracy by enabling three-dimensional evaluation of maxillary deficiency, mandibular prognathism, craniofacial asymmetry, and airway dimensions. CBCT-based cranial base assessment has enhanced understanding of sagittal discrepancies and Class III etiology. Additionally, three-dimensional soft tissue analysis refines esthetic evaluation, while digital dental models and virtual simulations support treatment planning decisions[2]. Advances in superimposition and artificial intelligence-based tools further improve growth assessment. Nonetheless, integrating clinical examination with radiographic and digital data remains essential for evidence-based and patient-centered care[13].

Current Trends in Growth Modification of Class Iii Malocclusion

Growth modification remains a key treatment modality for Class III malocclusion in growing patients, aiming to correct skeletal discrepancies by enhancing maxillary growth, restraining mandibular growth, or both. Traditional approaches such as facemask therapy are most effective during early mixed dentition but are often associated with dentoalveolar side effects[14]. Recent advances focus on maximizing skeletal effects while minimizing dental compensation through improved appliance design and anchorage systems. Skeletal anchorage–assisted maxillary protraction using miniplates or miniscrews has demonstrated superior orthopedic outcomes, producing greater maxillary advancement, improved sagittal jaw relationships, and favorable mandibular rotation with enhanced patient compliance[15]. Combination protocols incorporating rapid maxillary expansion and protraction, including alternate expansion–constriction techniques, further enhance sutural response. In contrast, chin cup therapy has shown limited true skeletal effects and is now less favored. Emphasis on optimal force vectors, vertical control, and individualized case selection has improved predictability[16]. Despite advances, residual mandibular growth necessitates long-term monitoring. Overall, contemporary growth modification strategies reflect a shift toward biologically driven, minimally invasive, and patient-centeredorthopedic management[17].While conventional facemask therapy remains widely used, it is often associated with dentoalveolar compensation and limited skeletal effects, particularly in older patients. In contrast, skeletal anchorage–assisted maxillary protraction has demonstrated significantly greater skeletal advancement with minimal dental side effects, as supported by recent systematic reviews and clinical trials[10]. However, controversy exists regarding the optimal timing and long-term stability of these approaches. Although skeletal anchorage shows promising short-term outcomes, long-term data remain limited, and residual mandibular growth continues to pose a challenge[10].

Orthodontic Camouflage in the Management of Class III Malocclusion

Orthodontic camouflage remains an important treatment option for patients with mild to moderate Class III malocclusion who are unwilling or unsuitable for orthognathic surgery. This approach aims to mask skeletal discrepancies through controlled dentoalveolar compensation rather than correcting the skeletal bases. Successful camouflage relies heavily on appropriate case selection, with favorable facial esthetics, minimal skeletal discrepancy, and stable growth patterns being key determinants. Biomechanically, camouflage treatment involves proclination of maxillary incisors and retroclination of mandibular incisors, often facilitated by selective extraction strategies[18]. Anchorage control is critical, and the use of temporary anchorage devices has significantly improved treatment predictability by enabling greater incisor retraction with minimal unwanted tooth movement[19]. Advances in digital treatment planning and clear aligner therapy have further expanded camouflage possibilities in carefully selected cases[20]. Soft tissue response and vertical dimension control play crucial roles in determining esthetic outcomes.

Although camouflage can provide satisfactory occlusal results, long-term stability and facial esthetic limitations necessitate careful planning, retention, and shared decision-making with patients[17].

Surgical Management of Class III Malocclusion and Virtual Treatment Planning:

Orthognathic surgery is the definitive treatment for severe skeletal Class III malocclusion when orthodontic camouflage fails to provide functional or esthetic improvement. Patients with significant maxillary deficiency, pronounced mandibular prognathism, or facial asymmetry are typical candidates. Common procedures include Le Fort I maxillary advancement and bilateral sagittal split osteotomy of the mandible, performed individually or in combination, with bimaxillary surgery often preferred to enhance facial balance and distribute surgical movements[21]. Contemporary trends favour maxillary advancement over isolated mandibular setback to preserve airway function and reduce obstructive sleep apnea risk[22].

Presurgical orthodontics is essential to decompensate dentoalveolar adaptations, revealing true skeletal discrepancies, though it may temporarily compromise esthetics. Surgery-first and surgery-early protocols minimize presurgical orthodontics, shortening overall treatment duration while maintaining outcomes[18]. Virtual surgical planning using 3D imaging, computer-assisted simulations, and integrated digital workflows improves precision, predicts postoperative esthetics, and facilitates interdisciplinary communication. CAD/CAM-fabricated surgical splints and rigid internal fixation enhance surgical accuracy and stability. Postoperative orthodontics ensures occlusal refinement and long-term stability, with relapse influenced by residual growth, surgical magnitude, and neuromuscular adaptation. Bimaxillary procedures generally show superior stability[23]. Psychological benefits, including improved self-perception and quality of life, are significant, though realistic expectations remain critical. Modern surgical management prioritizes precision, collaboration, and evidence-based, patient-centered care for optimal outcomes[24].

Surgery First v/s Conventional Orthodontics

The surgery-first approach has gained popularity due to reduced overall treatment duration and early improvement in facial esthetics. However, compared to conventional protocols, it presents challenges in occlusal stability, case selection, and treatment planning complexity. Current evidence suggests that while outcomes are comparable in selected cases, the conventional approach remains more predictable in patients with significant dental compensation or complex skeletal discrepancies[25].

Clear Aligners, Digital Orthodontics, and Artificial Intelligence in the Management of Class III Malocclusion:

Digital orthodontics has revolutionized the diagnosis and management of Class III malocclusion through advances in three-dimensional imaging, computational modeling, and artificial intelligence (AI). These technologies allow precise visualization of skeletal and dental discrepancies, improving treatment planning accuracy. Clear aligner therapy has emerged as an effective option for selected mild to moderate. Class III elastics and skeletal anchorage, including miniscrew-assisted aligner mechanics, enhance tooth movement control and reduce reliance on patient compliance[20].

Despite its advantages, artificial intelligence in orthodontics presents several limitations, including lack of standardized validation, potential algorithm bias, data privacy concerns, and limited long-term clinical evidence. Over-reliance on automated decision-making may also reduce clinician judgment. Therefore, AI should be considered an adjunct rather than a replacement for clinical expertise, and further high-quality research is required to establish its reliability and clinical applicability[26,27].

Long-Term Stability, Retention, and Relapse in the Management of Class III Malocclusion:

Long-term stability remains a central challenge in managing Class III malocclusion due to skeletal growth patterns, neuromuscular influences, and behavioral factors. Residual mandibular growth, particularly in adolescent patients, can alter occlusal relationships post-treatment, contributing to relapse. Growth modification therapies and orthodontic camouflage offer variable stability, with excessive dental compensation—such as mandibular incisor

retroclination—being prone to instability[28]. Retention strategies, including fixed and removable appliances, are critical for maintaining dental alignment, with long-term or permanent retention often recommended in high-risk cases. Skeletal anchorage, occlusal settling, soft tissue adaptation, and patient compliance further influence stability. Emerging digital technologies enable remote monitoring, early detection of relapse, and timely intervention[29]. Achieving durable results requires individualized retention plans, careful case selection, patient education, and management of realistic expectations to optimize both functional and esthetic outcomes in Class III malocclusion[30].

CONCLUSION

Management of Class III malocclusion requires a comprehensive, evidence-based, and individualized approach guided by accurate diagnosis and growth assessment. Skeletal anchorage–assisted growth modification offers improved orthopaedic outcomes in growing patients, while orthodontic camouflage remains appropriate for carefully selected mild to moderate cases. Orthognathic surgery continues to be the most predictable option for severe skeletal discrepancies, with digital planning enhancing precision and outcomes. Emerging technologies, including artificial intelligence and digital orthodontics, show significant potential but require further validation. Long-term stability remains a critical concern, emphasizing the importance of appropriate case selection, retention strategies, and patient compliance. Future research should focus on high-quality comparative studies to strengthen clinical decision-making in Class III malocclusion management.

ABSTRACT

The COVID-19 pandemic has profoundly impacted global physical, social, and psychological wellbeing, leading to a search for holistic and sustainable coping mechanisms. Yoga, as an ancient Indian discipline, offers a multidimensional approach for managing stress, immunity, and mental health during such crises. This study aimed to develop and validate a *COVID-19 Yoga Scale* (CYS) that conceptualizes the relationship between Yoga and wellbeing amid the pandemic. Using exploratory and confirmatory factor analysis (EFA and CFA), data were collected from 738 participants aged 16–60 years across four Indian states. The 49-item scale identified four sub-domains: Conspiracy, Location, Health, and Social Factors. The reliability coefficient (Cronbach's $\alpha = 0.94$) confirmed strong internal consistency. CFA demonstrated acceptable fit indices ($\chi^2/df = 2.14$, RMSEA = 0.045, CFI = 0.96, TLI = 0.95, GFI = 0.93), establishing robust construct validity. The results indicate that the COVID-19 Yoga Scale is a valid and reliable tool for assessing Yoga's conceptual and behavioral influence on health and wellbeing during pandemic conditions.

Keywords: Yoga, COVID-19, Scale Development, EFA, CFA, Psychometrics

INTRODUCTION

According to the World Health Organization (2020), the corona virus (COVID-19) pandemic has been affecting us since the end of 2019 and has significantly altered our way of life. These adjustments appear to have contributed to an increase in psychological suffering connected to the epidemic, such as anxiety, stress, perceived threat, and stress (Nikcevic et al.,2020). This was the initial cluster of the condition that would eventually be known as corona virus

illness (COVID-19). A Public Health Emergency of International Concern (PHEIC) had been declared by the WHO by January 30th 2020 as a result of the disease's rapid expansion to 18 countries outside of China with documented cases of human-to-human transmission (Riad et al.,2020). COVID-19 has a significant impact on people's health and welfare globally and is a primary cause of fear, stress, and anxiety (Reznik et al.,2020). As a result of rapid viral infections over the world, the number of affected persons and deaths has risen dramatically. COVID-19 is more likely to affect the elderly and individuals with underlying medical issues. According to resent research, corona viruses likely SARS and MERS are capable of modulating the host immune detection system (Sharma et al.,2024). The coronavirus pandemic, declared a global health emergency by the World Health Organization (WHO, 2020), has altered lifestyles and health perceptions worldwide. Alongside physical health risks, it triggered widespread psychological distress, including anxiety, fear, and social isolation (Nikčević&Spada, 2020; Reznik et al., 2021). Traditional Indian health systems such as Yoga and Ayurveda have been increasingly recognized for their potential to enhance immunity, resilience, and mental stability (Tillu et al., 2020; Choudhary et al., 2019).

Although several COVID-19-related psychological scales exist—such as the Fear of COVID-19 Scale (Ahorsu et al., 2020) and the COVID-19 Anxiety Syndrome Scale (Nikčević&Spada, 2020)—few have integrated *Yogic constructs* that assess holistic wellbeing. Thus, this study bridges that gap by conceptualizing and validating a COVID-19 Yoga Scale (CYS) designed to evaluate Yoga-related attitudes, beliefs, and behaviors that emerged during the pandemic. Recent studies highlight Yoga's role in post-COVID recovery and stress regulation (Gupta & Singh, 2024; Taneja& Sharma, 2023), reinforcing its importance as both a preventive and therapeutic practice. Therefore, the present research sought to develop a psychometrically sound scale that captures Yoga's multidimensional relevance during the pandemic. Yoga, Ayurveda and Homoeopathy are examples of traditional Indian health practices that have been shown to prevent, treat and control a variety of disease (Choudhary et al.,2019). In the Yoga scale of COVID-19 study the four domains i.e., Conspiracy, Health, Location and Self-awareness had been included. This study includes the questions related to each domains of COVID-19 which helps to find the review of each question related to COVID-19. This had been filled by 738 peoples from India through online and offline mode.

Objectives and Hypothesis

Objectives:

- To develop a standardized and validated scale reflecting Yoga concepts related to COVID-19.
- To identify and confirm the primary dimensions of Yoga responses during the pandemic.
- To assess the psychometric reliability and validity of the COVID-19 Yoga Scale through EFA and CFA.

Hypothesis:

It is hypothesized that the concept of Yoga in the context of COVID-19 can be represented as a multidimensional construct measurable through a valid and reliable scale.

Conceptual Frame:

The conceptual frame work of COVID-19 is designed on the basis of four COVID domains- Conspiracy, Location, Health, and Social Factors. Scale development of Yoga from COVID-19 using Dimension reduction- EFA, CFA factor methods (SPSS version 25) and discussion of Yoga in COVID-19.

METHODS

SAMPLING

A total of 738 participants (475 males, 263 females) aged 16–60 years were selected through convenience sampling from universities in Delhi, Haryana, Uttarakhand, and Uttar Pradesh. The sample size satisfied DeVellis's (2016) recommended ratio (1:15 to 1:20 items per participant). The study was conducted in Delhi, Haryana, Uttarakhand and Uttar Pradesh, India. A participant age range of 16 to 60 years was used as the inclusion criterion for the study. The people who gave their permission to collect the data were taken into account while choosing the sample size. Data were gathered between August 2021 and June 2022 using both online and offline questionnaires due to

pandemic restrictions. The instrument consisted of 49 items rated on a five-point Likert scale (1 = strongly disagree to 5 = strongly agree). Item Generation and Content Validity An initial pool of 58 items was generated based on a literature review and expert interviews in Yoga and health sciences. After expert evaluation using the Content Validity Index (CVI), items with CVI < 0.75 were removed, yielding 49 valid items. The four domains identified were:
Conspiracy (4 items)
Location (4 items)
Health (25 items)
Social Factors (16 items)
Face validity was confirmed through pilot testing with 35 respondents for readability and consistency. Students from each chosen university who agreed to take part in the study and give information were included. A ratio of 1:15 or 1:20 is suggested by DeVellis, R. F. (2016) as the best sample size. According to this standard, a sample size of at least 730 is sufficient. With their permission, we picked 738 people to test the psychometric properties. Data were collected from 1August to 30 June 2022. The demographic details of the subjects are given in Table 2.

Procedures of Scale Development

Scale development is a systematic process that is carried out at different stages of analysis. Following recommendations of DeVellis RF and Pasquali L scale development for the present study was accomplished in three stages viz; item generation, theoretical analysis and psychometric analysis.

Item Generation

The content domain was specified through review of literature related to yoga in COVD-19. Among the COVID-19 review four areas are considered which specify the content domain. The scale comprises of four concepts Conspiracy, Location, Health and Social factors. All four concepts were considered as scale development constructs by the researcher. Item pool generation gives the initial item pool a conceptual stamp of approval. According to Kapuscinski AN and Masters KS, the current study used a combination of deductive and inductive strategies to generate the first item pool. The researchers also spoke with specialists in the field of yoga science to gather qualitative information about the research's subject domains and goal. The information was analyzed and related with the concept of yoga in COVID-19 to generate initial items. As a result, 49 items were developed under the selected content domains.

Theoretical Analysis

Content Validity

The initial items content validity was tested to ensure that they were indicative of the defined construct i.e., Yoga in COVID-19. In order to assess the content validity of the initial items, the researchers conducted a thorough literature analysis and sought expert input to explicitly describe the conceptual framework of yoga in COVID-19. The expert panel consisted of four members from outside. The experts used CVI developed by Waltz (1981) to assess the relevance of items in respect to the content domain. provided by each item was deemed genuine and in accordance with the theory being The experts rated each item against a 4-point scale (1 = not relevant, 2 = somewhat relevant, 3 = quite relevant and 4 = highly relevant). A score of 3 or 4 means that the content measured, and they were kept. Items with a score of 1 or 2 were removed from the scale, indicating that they were theoretically or practically important questions, as well as any unclear items that appeared to repeat the basic substance of previous items.

Face Validity

The initial level scale was administered to 35 people to examine the tool's visual appearance, such as uniformity of style, formatting, readability, and feasibility, as instructed by Devon HA. The responders were asked to rate the tool's user-friendliness. To improve the instrument, the respondents' feedback was taken into account. This method proved useful in determining ambiguity and skewness, i.e., respondents providing a similar response for each item.

Psychometric Analysis

The psychometric analysis employs a variety of quantitative methodologies to assess the scale's construct validity and reliability. According to Posak off PM, construct validity is the amount of information that can be inferred from observed scores to hypothetical conceptions about which the observations are supposed to store information. The scale's convergent validity, criterion validity, and discriminate validity were all quantitatively examined in addition to its construct validity. To acquire consistent results of the psychometric indices, DeVellis RF strongly suggests combining exploratory factor analysis (EFA) with confirmatory factor analysis (CFA). Hence, these validity tests were done using EFA and CFA. Cron bach Alpha, Spearman–Brown coefficient, composite reliability, and average variance extraction were used to evaluate reliability, which is a quantification method that produces consistent results on repeated tests. The correlation between the results on the current scale and those on a known scale, the COVID-19 Yoga Scale, was used to determine concurrent validity.

Data Collection And Analysis

In this study, there were five possible responses on the scale, from "strongly disagree" (score 1) to "strongly agree" (score 5). Each item on the scale is a five-point Likert scale agreement statement, which is a quantitative method for measuring psychological aspects such as attitude, perception, anxiety, stress, beliefs, etc. The covid-19 Yoga Scale was acknowledged by every item on the scale. The total score across all items was used as the construct's quantifiable measure and was taken into account for all quantitative analytical tasks. The Likert scale's items were all regarded as continuous variables. To make it easier for responders to understand the statements, the scale was written in English. The respondents completed the questionnaire. EFA extracts the factors and proposes a factor structure that takes the correlation between the elements into account. The proposed factor structure is hypothesized and tested in CFA. It the statistical results fits with the hypothesized model the researcher can conclude that the factor structure is valid. Hence, the study evaluated the scale using both EFA and CFA. The Cronbach Alpha value, EFA, correlation matrix, and descriptive statistics were computed using IBM SPSS 25 software. CFA was carried out using IBM SPSS Amos 25, a version of the software. The Average Variance Extracted, a statistic derived from the values of factor loads, was used to confirm the convergence validity. Confirmatory factor analysis outputs such as the p value of Chi square, RMSEA, GFI, AGFI, CFI, TLI, NFI, and Chi sq/df were used to calculate model fitness indices in order to evaluate the construct validity. Through the use of Modification Indices, the degree of item redundancy was measured in order to test discriminate validity (MI).

RESULTS

General Characteristics of the Sample

A sample size of 738 healthy participants was selected for the study from the different universities of India covering both male 475 (66.39%) and female 263 (33.61%) populations. The demographic details of the subjects are given in Table 2.

Item Generation

We developed the instrument for COVID-19 Yoga Scale on the lines of methodology given by Montero I & León OG. As a result, based on the conceptual frame work of COVID-19 Yoga Scale. 49 items were developed under the selected major content domain viz; COVID-19 Yoga Scale. We divided the 49 items into four sub domains such as Conspiracy (4), Location (4), Health (25), Social Factors (16) were generated as the initial pool of items.

Theoretical Analysis

The initial item pool of 58 items was verified by four experts to determine whether the items, when taken collectively, provide an appropriate operational description of a construct, i.e., content validity. The experts reviewed the initial item pool using a CVI rating tool. Individually, the experts assigned a score. The index was determined for each item by dividing the number of experts who gave a rating of 3 or 4 by the total number of experts. Items with an index of less than 0.75 were deemed irrelevant, and they were removed from the original list. Nine items on the draft COVID-

19 were considered invalid from the initial pool because they yielded CVIs of 0.25 to 0.50 and were deleted if CVI was less than 0.75. All of the remaining items were found to be valid, with CVIs ranging from 0.75 to 1, resulting in a 49-item questionnaire. The scale was individually administered on 40 people after it was modified based on expert ratings. Each sentence was read aloud to the respondent, who then said what he or she had taken away from it. The item would be regarded qualified if the substance that the responder understood and what the researchers had conceived matched. The response would reveal difficulties such as vagueness, ambiguity, leading words/sentences, unfamiliar terminology, complicated sentences, closed-ended statements, and sensitive statements that were included in the items. Statements were rewritten based on this information. The changed statements were read to the respondent once more, and feedback was obtained and adjusted accordingly. Content validity testing and cognitive interviews with selected respondents resulted in the development of the 49 items.

Psychometric Analysis

Exploratory Factor Analysis (Efa)

The scale evolved after theoretical analysis with 49 items was administered to 738 participants. Exploratory factor analysis was conducted using the scores obtained from the survey. The Kaiser–Meyer-Olkin (KMO) measure was used to assess the sample adequacy and to prove the correlation matrix is an identity matrix Bartlett's Test of Sphericity is calculated. KMO value was 0.92 which was a excellent measure of Sampling Adequacy. Factor loading measures ranged from 0.40 to 0.90. Since all the factor load values of all the 49 variables were greater than 0.40, all of them were retained in the scale. Table 3 shows variance contributed by each factor and their corresponding Eigen values.

Confirmatory Factor Analysis (Cfa)

Confirmatory Factor Analysis (CFA) is a statistical technique used to assess the measurement properties of a set of observed variables and examine the underlying latent (unobserved) constructs or factors that these variables are intended to measure. It is a multivariate analysis method that is widely employed in the fields of psychology, social sciences, and market research. The primary objective of CFA is to test and validate a hypothesized factor structure by evaluating the fit between the observed data and a specified theoretical model. It allows researchers to determine whether the observed variables adequately represent the underlying constructs and to assess the relationships between these constructs. The researchers conducted a CFA applying a structural equation modeling to test a hypothetically developed factor structure through EFA with five latent factors and 49 observed variables. The model obtained from confirmatory analysis is presented in table.

Reliability

Internal consistency of the 49 item five factor scale was determined by calculating Cronbach's alpha measure and composite reliability measure. The Crobbach's alpha value was 0.94. Composite reliability measure was 0.94.

Scree Plot for COIVD-19 Scale

A scree plot is a graphical tool used in exploratory factor analysis (EFA) or principal component analysis (PCA) to determine the number of factors or components to retain from a dataset. It displays the eigen values associated with each factor or component extracted from the data. The scree plot is created by plotting the eigen values on the y-axis against the number of factors or components on the x-axis. Eigen values represent the amount of variance explained by each factor or component. Typically, eigen values are sorted in descending order before plotting, so the most important factors or components are on the left side of the plot. The scree plot helps in deciding how many factors or components should be retained for further analysis. The idea is to look for an "elbow" or a point in the plot where the eigen values drastically drop. This point indicates a significant drop in variance explained and suggests that the subsequent factors or components are less important. The scree plot of our data of 738 participants for COVID-19 scale is shown in the graph.

DISCUSSION

Systematic steps as prescribed in the literature of research were adopted to develop this scale. The COVID-19 Yoga scale developed based on the recent study of COVID-19 papers and literature review (deductive method) and consulted with relevant people about the subject (inductive method).The study followed established psychometric guidelines (DeVellis, 2016; Pasquali, 2020) for scale development and validation. The COVID-19 Yoga Scale demonstrated strong reliability, validity, and conceptual clarity. Its four domains—Conspiracy, Location, Health, and Social Factors—represent distinct psychosocial aspects of how individuals integrated Yogic understanding during the pandemic. The results align with prior scale developments such as the COVID-19 Phobia Scale (Arpaci et al., 2020) and the COVID-19 Anxiety Scale (Chandu et al., 2020), but uniquely include Yogic dimensions of holistic wellbeing. This highlights Yoga's adaptive role in enhancing mental and social resilience during health crises. The initial item pool, which had 58 items got reduced to 49 items with four constructs at the end of the study. It has been validated and found to be reliable by using the psychometric analysis. The stated hypothesis Yoga concept in COVID-19 may be related to scale development has been proved with final four regression coefficient values. These coefficients were calculated using EFA and CFA statistical analytical techniques on the lines of Barry to assess the influence of COVID-19 Yoga scale on social health and wellbeing. In terms of scale's validity, reliability and factor structure of COVID-19 Yoga scale. The results of this study suggest that the COVID-19 Yoga scale is providing an appropriate instrument for measuring the concept of Yoga in COVID-19.

Limitations and Future Scope

- The sample was limited to Indian states, reducing generalizability.
- Data relied on self-reported responses
- .Future studies should replicate the findings across diverse cultures and validate translations in regional languages. Longitudinal follow-ups may explore Yoga's sustained impact post-pandemic.

CONCLUSION

The COVID-19 Yoga Scale is a psychometrically robust instrument capturing Yoga's multidimensional contribution to health, resilience, and social wellbeing during the pandemic. The four-domain structure confirms that Yogic philosophy transcends individual health, influencing broader social and environmental harmony. The scale can serve as a valuable tool for researchers, educators, and policymakers to assess Yoga-based interventions in health crises and beyond. We employed both qualitative and quantitative methods to develop and validate this scale using SPSS version 25's exploratory and confirmatory factor analyses for 738 general populations from India. The standardized estimated regression value is found to be 0.67 which is greater than the required level of ≥ 0.5 and thus showing a good relation between four sub domains. This COVID-19 Yoga scale can facilitate and provide a social health care and wellbeing.

ABSTRACT

Sex determination from skeletal remains constitutes one of the four primary pillars of the forensic biological profile. Cranial sutures, long regarded as indicators of biological age, have recently gained renewed interest as anatomical substrates for AI-assisted sex estimation. Traditional morphoscopic and morphometric methods, while established, are constrained by observer subjectivity, population-specificity, and limited reproducibility. Advances in deep learning — particularly convolutional neural networks (CNNs) applied to computed tomography (CT) images — now offer a paradigm shift in forensic radiology. This systematic review synthesises the current evidence on AI-based image analysis of cranial structures — with particular emphasis on suture morphology and closure patterns — for sex determination in forensic contexts. It further evaluates methodological quality, model architectures, accuracy benchmarks, population representativeness, and future directions. A systematic search of PubMed, Scopus, Web of Science, and Google Scholar was conducted for studies published between 2015 and 2025, using PRISMA guidelines. Eligible studies included those applying machine learning or deep learning to cranial CT or radiographic imaging for sex or age-sex estimation from bony cranial features. Thirty-two studies met inclusion criteria. AI-based systems demonstrated classification accuracy ranging from 82% to 99.5% for sex estimation from cranial CT data, consistently outperforming conventional human assessors whose accuracy ranged from 61% to 92%. CNN architectures including VGG16, VGG19, ResNet50, InceptionV3, DenseNet121, and MobileNetV2 were most commonly employed. Explainability remains a critical gap, as deep learning models function as 'black boxes' that cannot readily identify

which anatomical features — including suture morphology — drive predictions. AI-enabled forensic radiology holds transformative potential for objective, reproducible, and scalable sex determination. Cranial suture analysis — when integrated into multimodal AI pipelines using CT imaging — emerges as a particularly promising subdomain. However, barriers including dataset size, population diversity, model interpretability, and medicolegal acceptance must be resolved before clinical and courtroom adoption. Future research should prioritise explainable AI (XAI), prospective multi-institutional validation, and the development of population-agnostic models.

Keywords: artificial intelligence, cranial sutures, sex determination, forensic radiology, deep learning, computed tomography, convolutional neural network

INTRODUCTION

Forensic identification of unknown human remains is one of the most consequential tasks in forensic medicine. When investigators recover skeletal remains — whether from a mass disaster, homicide, or archaeological context — establishing the biological profile of the individual is the critical first step toward identification. This biological profile encompasses four core parameters: sex, age at death, stature, and ancestry. Among these, sex estimation is foundational, as it immediately reduces the pool of potential matches by approximately fifty percent and contextualises the interpretation of all other biological indicators [1]. Cranial morphology has long served as a primary substrate for biological profiling. When the pelvis — the gold standard for sex estimation — is absent, incomplete, or poorly preserved, the skull becomes the next most reliable anatomical source of sexually dimorphic information. Male skulls typically exhibit greater robusticity, more pronounced supraorbital ridges, larger mastoid processes, squarer orbital margins, and more prominent nuchal crests compared to their female counterparts. These features, however, must be interpreted within a framework of considerable population-level and individual variation, rendering visual assessment inherently subjective [2] Cranial sutures — the fibrous joints uniting the bones of the calvaria — have been investigated for over a century primarily as indicators of biological age, given their well-documented pattern of progressive obliteration with advancing age. However, emerging evidence suggests that suture morphology, closure rates, and spatial distribution may also encode subtle sex-related information. The interplay between hormonal influences on bone metabolism and the biomechanical loading of the skull may produce detectable sex-dependent differences in sutural anatomy — differences that human observers, constrained by the limits of visual discrimination, may not reliably detect, but which machine learning algorithms may exploit [3]

The convergence of digital forensic radiology and artificial intelligence has created unprecedented opportunities for objective, reproducible, and quantitatively rigorous forensic analysis. Postmortem computed tomography (PMCT) — now routinely employed in many forensic departments worldwide — generates high-resolution three-dimensional reconstructions of the skull that can serve as inputs to deep learning models. These models, particularly convolutional neural networks (CNNs) trained on large imaging datasets, have demonstrated remarkable accuracy in sex classification tasks, in many cases surpassing the performance of expert human assessors. Yet, the specific contribution of cranial suture analysis within these AI frameworks remains under characterised. Most published studies have focused on global skull morphology or selected anatomical landmarks such as the supraorbital ridge, nuchal crest, mastoid process, and foramen magnum — without isolating the analytical contribution of suture-specific features. This represents a significant gap in the literature, given the forensic relevance of sutures (they are often the most durable and identifiable cranial features in decomposed or fragmentary remains) and their established role in age estimation methodologies [4]. This systematic review aims to synthesise and critically evaluate the existing evidence on AI-based cranial image analysis for sex determination, with particular attention to the role of cranial sutures and CT-based imaging modalities. We further outline the methodological landscape of current machine learning approaches, identify key limitations, and propose a research agenda for the future development of robust, population-inclusive, and legally defensible AI forensic tools [5].

Background and Theoretical Framework

Sexual Dimorphism of the Skull

Sexual dimorphism in the human skull arises primarily from divergent hormonal trajectories during adolescent development. Androgenic hormones in biological males promote greater overall bone mass, increased cortical thickness, and enhanced muscular attachment sites, resulting in the characteristic robusticity of the male cranium. In contrast, female skulls tend to be smaller, smoother, and more gracile, with less pronounced brow ridging and more rounded orbital margins. The degree of dimorphism, however, is not uniform across populations — it is known to be influenced by ancestry, nutritional history, and secular trends in stature and physique [6]. Morphoscopic assessment of cranial sex,systematised by Walker (2008) using five key traits — glabella, supraorbital margin, nuchal crest, mastoid process, and mental eminence — has been widely adopted in forensic practice. Walker's discriminant function analysis demonstrated classification accuracies of 77% to 92% depending on population and trait combinations. Subsequent validation studies, however, have revealed that these models perform less reliably when applied to populations outside the original reference samples, raising concerns about transferability. In the absence of the pelvic girdle, skulls alone can achieve approximately 80% accuracy in sex estimation under traditional methods — a figure that rises to 90% when the mandible is intact and approaches 96–98% when a complete skeleton is available [7].

Craniometric approaches using discriminant function analysis and the Fordisc 3.1 software package have supplemented morphoscopic methods, offering probabilistic outputs based on linear cranial measurements. More recently, three-dimensional geometric morphometricshave revealed sex-dependent shape variation across the cranial vault and base that transcends simple linear measurement, capturing complex surface topography that is invisible to traditional caliper-based methods. These geometric approaches have demonstrated accuracies exceeding 90% in well-sampled populations, and they provide the conceptual bridge to AI-based image analysis, which similarly operates on shape and intensity information extracted from imaging data [8].

Cranial Sutures: Anatomy, Function, and Forensic Relevance

Cranial sutures are syndesmotic fibrous joints connecting the flat bones of the neurocranium. The major ectocranial sutures include the coronal suture (joining the frontal and parietal bones), the sagittal suture (joining the two parietal bones at the midline), and the lambdoid suture (joining the parietal bones to the occipital bone). Additional sutures of forensic relevance include the squamous, sphenofrontal, sphenotemporal, and median palatine sutures. Suture closure — the process of obliteration of the fibrous joint by osseous bridging — progresses broadly with age, forming the basis of suture-based age estimation methods pioneered by Todd and Lyon in the 1920s and subsequently refined by Meindl and Lovejoy (1985), whose ten-site ectocranial suture scoring system remains widely cited. However, the forensic utility of suture-based age estimation has been substantially questioned: the relationship between closure and chronological age exhibits enormous individual variability, such that the standard errors of age predictions using suture closure alone commonly exceed 15 years in adults. Critics have argued that suture evaluation in isolation contributes minimally to forensic age assessment [9].

Nevertheless, sutures retain considerable forensic importance for several reasons. First, the cranium — and specifically the calvarial bones bearing the major sutures — is among the most taphonomically resistant elements of the human skeleton, surviving conditions of decomposition, burning, fragmentation, and excavation that destroy more fragile postcranial elements. Second, a growing body of evidence suggests that suture morphology is influenced by sex-related biological processes. A 2023 Indian population study using 3D CT scans of 263 individuals found statistically significant sex differences in the closure patterns of the sagittal (S1 segment), coronal (RC1, RC2, LC1, LC2 segments), and lambdoid (LL1 segment) sutures, with males demonstrating earlier and more extensive obliteration in specific suture segments. These sex-related differences in closure timing, if reliably detectable by AI systems, could provide an additional discriminating feature in multi-parameter forensic classification models [10]. The advent of postmortem CT as a routine forensic tool has transformed suture assessment. Where traditional methods required removal of scalp and temporal muscles to visualise the ectocranial surface — a destructive process

incompatible with body preservation requirements in many jurisdictions — CT enables non-invasive, three-dimensional visualisation of both ecto- and endocranial suture surfaces simultaneously. Multiplanar reconstruction (MPR) and volume rendering techniques (VRT) further enhance the clarity and quantifiability of suture imaging [11].

Artificial Intelligence in Medical and Forensic Imaging

Artificial intelligence, and deep learning in particular, has catalysed a revolution in medical imaging over the past decade. Convolutional neural networks — biologically inspired architectures that apply learnable filter banks to extract hierarchical representations from image data — have achieved or exceeded human performance in tasks ranging from radiographic fracture detection and diabetic retinopathy grading to histopathological cancer classification. The foundational architectures underpinning most forensic imaging studies include VGG16, VGG19, ResNet50, InceptionV3, MobileNetV2, DenseNet121, and EfficientNet, all of which were originally developed for general-purpose image classification on the ImageNet dataset and subsequently adapted via transfer learning to specialised medical imaging tasks. Transfer learning — the practice of initialising a model with weights pre-trained on a large general dataset and then fine-tuning it on a smaller domain-specific dataset — is especially valuable in forensic radiology, where labelled imaging datasets are inherently limited by the rarity and sensitivity of medicolegal cases. By leveraging the feature hierarchies learned from millions of photographic images, transfer learning enables meaningful classification even with datasets of a few hundred to a few thousand cases — a scale typical of published forensic CT studies [12,13].

Beyond standard CNN architectures, newer paradigms have emerged with particular relevance to forensic skull analysis. Multiple-instance learning (MIL) — which treats a three-dimensional CT scan as a 'bag' of two-dimensional slice instances and learns to classify the bag from the distribution of instance-level features — is well-suited to volumetric CT data where the discriminating anatomical information is distributed across many slices. Siamese neural networks, which learn similarity metrics between pairs of specimens, offer promise for retrieval-based forensic identification. Attention-gated architectures, which weight different image regions according to their relevance to the prediction, offer a degree of spatial interpretability that is forensically important: investigators need to know not just what the model predicted, but which anatomical regions drove that prediction [14].

METHODS

Search Strategy

A systematic literature search was conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guidelines. Electronic databases searched included PubMed/MEDLINE, Scopus, Web of Science, and Google Scholar. The search was restricted to publications from January 2015 to April 2025, reflecting the period of significant AI advancement in medical imaging. Search terms were constructed using Boolean operators and MeSH vocabulary, combining the domains of: (1) artificial intelligence, machine learning, deep learning, convolutional neural network; (2) cranial sutures, skull, calvaria, cranial morphology, craniometry; (3) sex estimation, sex determination, sexual dimorphism, forensic anthropology, biological profile; and (4) computed tomography, forensic radiology, postmortem CT, cephalometric radiograph. A total of 847 records were initially identified across all databases. After deduplication (n=214 removed), 633 records underwent title and abstract screening. Full-text review was performed for 89 articles. Thirty-two studies ultimately met all inclusion criteria. Reference lists of included articles were hand-searched, yielding four additional eligible studies. Studies were excluded if they: were purely traditional anthropometric in methodology (no AI component); did not use imaging data; focused exclusively on dental, postcranial, or non-cranial structures; or reported insufficient methodological detail for quality assessment.

Inclusion and Exclusion Criteria

Inclusion criteria required studies to: (1) apply at least one machine learning or deep learning algorithm; (2) use cranial imaging data (CT, CBCT, cephalometric radiograph, or 3D surface scan); (3) include sex estimation or sex-informed classification as a primary or secondary outcome; (4) report quantitative performance metrics (accuracy, sensitivity, specificity, AUC); and (5) involve human skeletal or radiographic data. Studies using exclusively synthetic data, cadaveric specimens without radiographic imaging, or living subjects in non-forensic contexts were excluded unless their methodological findings were directly transferable to forensic applications.

Quality Assessment

Methodological quality was assessed using a modified QUADAS-2 (Quality Assessment of Diagnostic Accuracy Studies) framework adapted for AI imaging studies. Key domains evaluated included: representativeness of the study population, imaging protocol standardisation, transparency of AI model architecture and hyperparameter reporting, handling of class imbalance, validation strategy (internal vs. external), and degree of interpretability analysis. Studies were rated as low, moderate, or high risk of bias across these domains. Risk of bias did not result in exclusion but is reported narratively in the synthesis.

RESULTS

Overview of Included Studies

The 32 included studies were published between 2018 and 2025, with a pronounced clustering after 2021 reflecting the rapid proliferation of AI applications in forensic imaging. Geographically, studies were conducted in Asia (n=18; predominantly Indonesia, Japan, South Korea, China, and Thailand), Europe (n=8; primarily Eastern Europe and Italy), Australia (n=3), and the Americas (n=3). This distribution reflects both the availability of forensic CT infrastructure and the composition of institutional skeletal reference collections in these regions. Sample sizes varied considerably, ranging from 85 to 2,041 CT scans per study. The majority of studies (n=24) used retrospective clinical or forensic CT archives, while eight studies employed dedicated research datasets including the New Mexico Decedent Image Database (NMDID) — the largest publicly available postmortem CT repository. Sex representation was broadly balanced in most studies, though several noted overrepresentation of male subjects due to the higher proportion of male forensic cases, which may introduce classification bias.

AI Model Architectures and Performance

CNN-based architectures dominated the included studies. VGG16 and VGG19 were most frequently employed (n=14 studies), followed by ResNet50/ResNet50V2 (n=11), InceptionV3 and InceptionResNetV2 (n=9), MobileNetV2 (n=8), and DenseNet121 (n=6). More recent studies employed EfficientNet (n=4) and custom hybrid architectures combining attention mechanisms with established backbones. Classification accuracy for sex estimation from cranial CT ranged from 82.4% to 99.5% across studies. The highest accuracy (99.5% mean average precision, mAP@50) was reported by a 2025 study from Thammasat University examining lateral skull CT images with a YOLO-based object detection model augmented with extensive data augmentation, focusing on the supraorbital ridge and nuchal crest in a Thai population. A landmark 2024 study by Lye et al. (Scientific Reports) — employing 200 cranial CT scans of Indonesian individuals and comparing a deep learning multi-task network against a trained human observer using Walker's (2008) standard — found that the best-performing DL network achieved 97% accuracy compared to 82% for the human assessor. The DL model was further enhanced by multi-task learning, in which it simultaneously predicted Walker cranial trait scores and sex classification, suggesting that incorporating anthropologically-grounded cranial landmarks into AI training pipelines improves both accuracy and interpretability.

A gated attention-based multiple-instance learning (MIL) model applied to 3D skull images reconstructed from postmortem head CT scans of East Asian cadavers (Kondou et al., 2023; Nature Scientific Reports) achieved 92% accuracy in females and 95% in males, outperforming three forensic scientist assessors whose accuracy ranged from

61–89%. A parallel study on sex estimation from skull CT images using deep feature selection and feature fusion (Ciftci et al., 2024; Scientific Reports) reported overall accuracy of 96.4%, with precision of 96.1% for males and 96.8% for females. Forensic identification using Siamese neural networks applied to NMDID DICOM data further demonstrated the potential of contrastive learning frameworks, with hybrid CNN-contrastive embedding models achieving 91% accuracy in multi-institutional CT data. For cephalometric radiograph-based studies, accuracies were somewhat lower, ranging from 76% to 90.7%, with the most comprehensive study (340 cephalometric images of Indonesian subjects; 2025) reporting that InceptionResNetV2 performed best among six CNN architectures tested (VGG16, VGG19, MobileNetV2, ResNet50V2, InceptionV3, InceptionResNetV2), with VGG16 and VGG19 performing competitively in earlier Indonesian population research achieving accuracies of approximately 84–87%.

Role of Cranial Sutures in AI-Based Sex Estimation

Despite their anatomical prominence and established role in forensic anthropology, cranial sutures have received comparatively little dedicated attention in AI imaging studies for sex determination. The majority of studies that achieved high accuracy focused on global skull morphology, overall size and shape, or specific landmarks such as the supraorbital ridge, glabella, mastoid process, nuchal crest, mental eminence, and foramen magnum — without isolating the informational contribution of suture features.[15] The most direct evidence for sex-related suture variation comes from non-AI radiological studies. A 2023 Indian population CT study (n=263) demonstrated statistically significant sex differences in cranial suture closure patterns using 3D CT with volume rendering — specifically in the sagittal (S1), coronal (RC1, RC2, LC1, LC2), and lambdoid (LL1) suture segments. Males exhibited earlier and more complete obliteration in these segments. This pattern is consistent with the known effect of testosterone on osteoblastic activity and may reflect sex-divergent patterns of sutural fusion. Similar findings have been reported in European, Japanese, and Chinese populations, suggesting a degree of universality in suture-sex relationships, though the magnitude of differences is population-dependent.[16]

Machine learning has been applied specifically to age estimation from cranial sutures via CT. A 2024 study of 132 Northern Chinese Han adults used CT-multiplanar reformation of cranial sutures and applied four machine learning classifiers — including support vector machines and ensemble models — to suture closure scoring data, achieving improved age prediction accuracy over traditional linear regression. Crucially, the study stratified results by sex, demonstrating differential model performance that indirectly confirms sex-specific suture closure dynamics. Nikolova et al. (2021; Forensic Imaging) applied machine learning techniques to sagittal suture maturation data and demonstrated that algorithmic approaches to suture scoring outperform traditional visual staging, particularly when combined with ancillary morphological features [17]. The Grad-CAM (Gradient-weighted Class Activation Mapping) visualisations reported in several deep learning sex estimation studies provide indirect evidence for the contribution of suture regions. In the Lye et al. (2024) study, Grad-CAM maps showed that the DL model appeared to allocate significant attention to regions overlapping the coronal and sagittal sutures, in addition to the expected dimorphic landmarks. This suggests that AI models may be implicitly learning suture-based features without explicit anatomical labelling — a finding with important implications for understanding what these models detect. A dedicated study specifically segmenting and isolating suture regions as input features to CNN or attention-based models would be highly informative and represents an urgent gap in the literature.[18]

The foramen magnum — a region anatomically adjacent to the lambdoid suture — has been specifically targeted for AI-based sex estimation. A 2025 ScienceDirect study employing object detection and instance segmentation on foramen magnum CT images achieved 65.68% and 62.69% accuracy respectively, noting that these figures were lower than traditional morphometric approaches. This finding underscores that not all cranial regions are equally informative, and that AI model performance is highly dependent on the anatomical region selected for analysis and the quality of the training dataset.[19]

Imaging Modalities and Technical Considerations

Computed tomography — specifically multislice CT (MSCT) and postmortem CT (PMCT) — is the dominant imaging modality across included studies, reflecting its capacity for high-resolution three-dimensional bone visualisation without tissue dissection. Standard CT acquisition parameters varied across studies: slice thickness ranged from 0.5 mm (high resolution) to 5 mm, with thinner slices providing superior detail for suture visualisation but generating larger datasets that increase computational demands. Most studies used bone algorithm reconstruction for maximal spatial resolution, which reduces soft tissue blur relevant to cranial surface and suture analysis.[20] Three-dimensional reconstruction techniques — including maximum intensity projection (MIP), multiplanar reformation (MPR), and volume rendering technique (VRT) — were used in most studies to generate the skull surface representations that serve as CNN inputs. The volumetric nature of CT data presents a methodological choice: studies may either convert 3D data to 2D projections (lateral, anterior-posterior, or oblique views) for input to standard 2D CNNs, or employ true 3D convolutional networks or multiple-instance learning frameworks that process the full volumetric information. The former approach sacrifices depth information but leverages the larger body of pre-trained 2D CNN weights; the latter is computationally intensive but theoretically retains all available diagnostic information. Bewes et al. demonstrated 95–96% accuracy using 2D projections of 3D reconstructions, while 3D MIL-based models (Kondou et al.) achieved comparable performance, suggesting that 2D projections may preserve sufficient discriminating information for sex classification at the global skull level.[21]

Cone beam CT (CBCT), which offers higher resolution at lower radiation doses and cost compared to MSCT, has been explored in several studies. A 2024 study applied the GADNN hybrid deep learning architecture to CBCT images of maxillary and frontal sinuses for age and sex determination, reporting high accuracy. CBCT may be particularly relevant for suture analysis given its superior resolution of fine cortical bone interfaces. Lateral cephalometric radiographs, while two-dimensional and limited in information content compared to CT, remain practically important in contexts where CT is unavailable — including historical forensic archives and resource-limited settings — and have yielded accuracies of 84–90% in well-controlled CNN studies.[22]

Population Diversity and Generalisability

A major limitation of the current evidence base is its geographic and demographic skew. The majority of high-accuracy studies have been conducted on East and Southeast Asian populations — predominantly Indonesian, Japanese, Thai, and Chinese cohorts — for whom institutional CT archives and forensic anthropological infrastructure are well-developed. European studies have focused on Italian, Croatian, Bulgarian, and Eastern European populations. Studies from South Asian, sub-Saharan African, Middle Eastern, and Latin American populations are conspicuously underrepresented, despite the forensic relevance of these populations.[23]

This demographic skew matters profoundly for sex estimation accuracy because sexual dimorphism is known to be population-specific in its expression. A model trained exclusively on East Asian skulls — with their characteristic cranial morphology — may perform poorly on South Asian or African skulls. The degree to which AI models trained on one population generalise to another has been explicitly tested in only a minority of studies, with results uniformly showing accuracy degradation in cross-population application. Population-specific formulae are generally required for reliable forensic work — a constraint that applies equally to AI models and to traditional morphometric methods.[24]

DISCUSSION

Paradigm Shift: From Subjective Assessment to Algorithmic Classification

The consistent finding across this systematic review — that AI models achieve accuracy rates of 90–99% in cranial sex estimation while outperforming trained human assessors operating at 61–92% — represents more than a quantitative improvement. It reflects a qualitative shift in the epistemology of forensic cranial analysis. Human assessors, however experienced, are subject to cognitive biases, inter-observer inconsistency (particularly in populations

outside their training), and perceptual limitations that constrain the ceiling of achievable accuracy. AI systems, while not immune to systematic error, can maintain consistent classification criteria across thousands of specimens and can be explicitly validated against population-specific reference data. The multitask learning approach demonstrated by Lye et al. (2024) — in which the AI simultaneously learns traditional cranial trait scores (following Walker's framework) and sex classification — is particularly significant. By grounding AI learning in anthropologically validated landmarks, this approach produces models that are not only accurate but partially interpretable through the lens of established forensic practice. The DL model's learned attention to cranial trait regions, as visualised by Grad-CAM, affirms that the AI is capturing anatomically meaningful information rather than artefactual correlates.

The Suture Problem: Underexplored but High-Potential

Cranial sutures represent what may be described as the unexplored frontier in AI forensic cranial analysis. Their significance as taphonomically durable anatomical features, their documented sex-related variation in closure patterns, and their geometric complexity — which renders visual human assessment unreliable but which AI pattern recognition may excel at — make them a compelling target for dedicated AI investigation. Current studies have demonstrated that sex differences exist in suture closure rates and that machine learning improves the precision of suture-based age estimation; the logical next step is a study specifically designed to evaluate whether suture texture, morphology, and closure pattern can serve as independent or supplementary predictors of sex. The integration of radiomic features — quantitative descriptors of image texture, intensity, and spatial patterns extracted from CT data — with suture region of interest segmentation is a particularly promising methodological approach. Radiomics has been successfully applied to CT-based sex estimation in adjacent domains (e.g., orbital region, frontal sinus morphology), and its application to specifically segmented suture regions could reveal hidden sex-discriminating information invisible to conventional analysis. Deep learning-based radiomics, which learns task-relevant features automatically rather than relying on hand-engineered descriptors, represents the most advanced iteration of this approach.

Explainability: The Critical Medicolegal Challenge

For AI tools to be admissible in forensic and medicolegalproceedings, they must not only be accurate — they must be explainable. Courts and regulatory bodies in most jurisdictions require that forensic methods be validated, reproducible, and interpretable: examiners must be able to articulate the basis for their conclusions. The 'black box' nature of deep learning represents a fundamental barrier to courtroom adoption. While Grad-CAM and SHAP (SHapley Additive exPlanations) visualisation techniques provide post-hoc spatial attention maps, they do not constitute mechanistic explanations of model decision-making.[25] Explainable AI (XAI) — a field specifically concerned with rendering machine learning decisions transparent and interpretable — has produced several architectures relevant to forensic radiology. Attention-gated CNNs highlight the most influential image regions for classification. Concept-based explanation methods learn human-understandable concepts (such as 'prominent supraorbital ridge' or 'open sagittal suture') and map them to model outputs.[26] Prototype-based networks classify by similarity to learned representative examples, facilitating natural language justification of predictions. The forensic community should engage proactively with the XAI research community to co-develop explanation frameworks that satisfy both scientific rigour and medicolegal standards.[27]

Ethical, Legal, and Practical Considerations

The deployment of AI in forensic sex estimation raises several ethical considerations that extend beyond technical performance. The use of 'sex' in forensic biological profiling refers to biological sex as inferred from skeletal morphology — a construct that may diverge from an individual's gender identity. Forensic anthropologists and legal practitioners must communicate this distinction carefully to avoid misidentification or misrepresentation of decedents. AI systems trained on binary classification frameworks may further reinforce oversimplified conceptualisations of biological sex variation. Data privacy and security present additional concerns. The construction of large forensic CT datasets for AI training requires careful governance of sensitive postmortem imaging data. Institutional review board oversight, data anonymisation, and compliance with regional medicolegal

regulations governing postmortem imaging are prerequisites for ethical AI development in this domain. The emergence of federated learning — a paradigm in which AI models are trained collaboratively across institutions without sharing raw patient data — offers a pathway to large-scale, privacy-preserving dataset construction.

Practical barriers to AI adoption in forensic radiology include the cost of CT infrastructure (particularly in resource-limited forensic systems), the need for specialised computational hardware for model training and inference, and the absence of standardised validation protocols that would allow comparison of model performance across studies. Regulatory frameworks for AI medical devices — including the FDA's Digital Health Centre of Excellence guidance in the United States and CE-mark requirements in the European Union — are rapidly evolving and will shape the pathway to clinical and forensic deployment.

Future Directions

Based on the evidence synthesised in this review, we propose the following priorities for the field. First, dedicated studies on cranial suture-specific AI analysis are urgently needed. These should employ precise segmentation of suture regions from CT data, test multiple AI architectures on suture features in isolation and in combination with other cranial features, and evaluate whether suture analysis adds discriminative power over global skull morphometry alone. Second, population diversity in AI training datasets must be addressed. International consortia modelled on the Global Digital Skull Repository or the NMDID should be expanded to include underrepresented populations, particularly from South Asia, sub-Saharan Africa, and the Middle East. Third, XAI methods must be systematically integrated into AI forensic sex estimation pipelines from the outset — not retrofitted as post-hoc explanations. Fourth, prospective multi-institutional validation studies are required to establish the real-world performance of AI tools under the varying conditions of forensic casework. Fifth, regulatory pathway development for AI forensic tools should be pursued proactively by forensic medical associations, ideally in collaboration with existing forensic standards bodies such as the Scientific Working Group for Forensic Anthropology (SWGANTH) and the Forensic Science International community.

CONCLUSION

Artificial intelligence — and deep learning applied to computed tomography imaging in particular — has demonstrated compelling evidence of transformative potential for sex determination in forensic radiology. The consistent superiority of AI over trained human assessors in controlled studies, the capacity for non-destructive and reproducible skull analysis through CT, and the emerging evidence for sex-related information encoded in cranial suture morphology collectively support the case for sustained investment in this field. Cranial sutures, long underutilised in sex estimation, may emerge as a particularly valuable feature domain for AI analysis, given their durability, their documentable sex-related variation in closure dynamics, and the geometric complexity of their morphology — features that precisely match the strengths of deep learning pattern recognition. Future research that specifically isolates and analyses suture regions using explainable AI architectures, and that validates models across diverse global populations, will be essential to realising this potential. The forensic radiology community stands at a pivotal juncture: the tools to revolutionise biological profile construction are increasingly available, but their responsible, equitable, and legally defensible implementation requires rigorous scientific standards, transparent AI design, and meaningful engagement with the ethical dimensions of AI-assisted forensic identification. This review provides a foundation for that endeavour.

ABSTRACT

Web Application Firewalls (WAFs) are a critical first line of defense in protecting web applications from malicious traffic. However, traditional WAFs relying on static pattern matching are increasingly vulnerable to sophisticated evasion techniques and often suffer from high false-positive rates. This paper introduces an enhanced, context-aware WAF designed to address these limitations. Operating as a lightweight reverse proxy, our implementation moves beyond simple signature matching by incorporating a cumulative threat-scoring engine. This engine analyzes multiple request attributes, assigning weighted scores to suspicious patterns to make more intelligent blocking decisions, thereby significantly reducing false positives. To counter adversarial attacks, the WAF employs a robust input normalization pipeline that neutralizes common evasion tactics such as multi-layer URL encoding and HTML entity obfuscation. Furthermore, its threat detection capabilities have been expanded to cover modern, critical vulnerabilities, including Server-Side Request Forgery (SSRF) and JWT alg:none manipulation. Empirical evaluation using a dedicated benchmarking suite demonstrates the WAF's effectiveness, achieving a 98.6% detection rate across a diverse set of attack vectors, including obfuscated payloads, with a 0% false positive rate and minimal performance overhead. These results validate our approach as an effective, resilient, and lightweight solution for securing modern web applications.

Keywords: Web Application Firewall (WAF), Threat Scoring, Adversarial Robustness, False Positives, SSRF, JWT Security, Cybersecurity, Input Normalization

INTRODUCTION

In the contemporary digital landscape, web applications have become indispensable, serving as the primary interface for everything from e-commerce and social networking to critical enterprise operations. This ubiquity, however, makes them a prime target for a wide array of cyber threats. Malicious actors continuously devise new methods to exploit vulnerabilities, with common attacks like SQL Injection (SQLi), Cross-Site Scripting (XSS), and Denial-of-Service (DoS) remaining persistent dangers. To counter these threats, Web Application Firewalls (WAFs) have been established as a critical security control, acting as a shield that inspects and filters HTTP/HTTPS traffic between clients and the web server. By operating at the application layer (Layer 7), a WAF can provide a level of security that traditional network firewalls cannot, offering a vital barrier against application-specific attacks. Despite their importance, many WAF solutions, particularly traditional signature-based systems, exhibit significant limitations in the face of modern, sophisticated attacks. Their reliance on static pattern matching makes them predictable and susceptible to common evasion techniques, where attackers use methods like multi-layer encoding, case manipulation, or character obfuscation to disguise malicious payloads and bypass static rules. This rigidity not only creates security gaps but also frequently leads to a high rate of false positives, where legitimate user requests are incorrectly flagged as malicious, causing service disruptions and a poor user experience. Furthermore, the threat landscape is not static; attackers are constantly developing exploits for new classes of vulnerabilities, such as Server-Side Request Forgery (SSRF) and API-focused attacks like JWT token manipulation, which many legacy WAFs are not equipped to detect.

This paper addresses these shortcomings by proposing an enhanced, lightweight, and context-aware WAF. Our implementation moves beyond the limitations of static analysis by introducing a dynamic, cumulative threat-scoring engine. Instead of making a binary block/allow decision based on a single rule match, our WAF evaluates multiple characteristics of an incoming request, assigning weighted scores to various indicators of malicious intent. A request is only blocked if its total accumulated score surpasses a configurable threshold, a method that provides greater context and dramatically reduces false positives. This core logic is supplemented by a robust input normalization pipeline to proactively neutralize adversarial evasion tactics and an expanded rule set designed to identify and mitigate emerging threats, including SSRF and JWT manipulation attacks. The objective of this work is to present and validate a WAF architecture that is not only more resilient to modern attack vectors but also more intelligent in its decision-making process. This paper is structured as follows: Section 2 provides a review of the relevant literature in WAF technologies. Section 3 details the core design and architecture of our proposed WAF, with a focus on its threat-scoring and input normalization mechanisms. Section 4 outlines the methodology for our empirical evaluation, including the benchmark suite and testing environment. Section 5 presents and discusses the results of our security and performance tests, quantifying the WAF's detection rate, false positive rate, and latency overhead. Finally, Section 6 concludes with a summary of our findings and suggests directions for future research.

LITERATURE REVIEW

Design and development

The design of our enhanced Web Application Firewall (WAF) is guided by principles of resilience, context-awareness, and low-latency performance. It is architected to overcome the limitations of static, signature-based systems by integrating intelligent analysis modules. This section details the core architecture, technology stack, and key functional components of the WAF.

Core Architecture

The WAF operates as a reverse proxy, positioning itself as an intermediary between the client and the backend web application. This non-intrusive architecture ensures that it can be deployed in front of any existing web service without requiring modifications to the application itself. Every incoming HTTP/HTTPS request is first intercepted by

the WAF, where it undergoes a multi-stage analysis pipeline before a decision is made to either block it or forward it to the protected application.

The request processing workflow is as follows:

- **Ingestion:** The WAF receives the client's raw HTTP request.
- **Stateful Check:** The source IP is checked against the rate-limiting and ban lists.
- **Normalization:** All user-controllable inputs (URL parameters, POST bodies, specific headers) are passed through the Input Normalization Pipeline to canonicalize the data.
- **Threat Analysis:** The normalized data is analyzed by the Cumulative Threat-Scoring Engine, which inspects it for various attack patterns.
- **Decision and Action:** Based on the final aggregated threat score, the WAF either:
  - **Blocks** the request and returns a 403 Forbidden response.
  - **Bans** the source IP if the score exceeds a higher threshold.
  - **Forwards** the legitimate request to the backend application and returns the application's response to the client.

Technology Stack

To achieve a balance of performance and flexibility, the WAF was developed using a carefully selected set of technologies:

- **Python:** The core programming language, chosen for its powerful standard library, extensive support for third-party packages, and suitability for rapid development.
- **Flask:** A lightweight and versatile web framework used to build the reverse proxy server. Its minimalism ensures that the WAF itself introduces minimal performance overhead.
- **Redis:** A high-performance, in-memory key-value store. Redis is leveraged for all stateful operations, including managing rate-limit counters and maintaining the list of temporarily banned IP addresses. Its speed is critical for ensuring that these checks do not become a bottleneck.

Input Normalization Pipeline

A primary defense against adversarial attacks is the WAF's input normalization pipeline. Attackers frequently attempt to bypass security filters by obfuscating malicious payloads. This pipeline is designed to reverse these common evasion techniques by converting all input to a clean, canonical format before analysis. This critical pre-processing step, implemented in the normalize_input function, includes:

- **Multi-Pass URL Decoding:** Requests are subjected to multiple rounds of URL decoding. This is essential for defeating multi-layer encoding attacks where malicious characters (e.g., <) are encoded multiple times (e.g., %3c becomes %253c).
- **HTML Entity Decoding:** The pipeline decodes HTML entities (e.g., < is converted to <), preventing attackers from using this format to hide XSS payloads.
- **Lowercase Conversion:** All input is converted to lowercase to enable case-insensitive pattern matching, rendering evasion tactics like <ScRiPt> ineffective.

Cumulative Threat-Scoring Engine

The centerpiece of the WAF's intelligent design is its cumulative threat-scoring engine, which replaces rigid, binary rule matching with a more nuanced, context-aware approach. Instead of blocking a request upon the first match of a suspicious pattern, the engine assigns a pre-defined weighted score to each detected anomaly.

Scores are assigned based on the confidence level of the indicator. For instance:

- A simple SQL comment (--) might receive a low score (e.g., 3), as it can appear in legitimate contexts.
- A classic SQLi tautology (e.g., 'a'='a') is assigned a higher score (e.g., 10).
- A highly confident indicator of an attack, such as a stacked SQL query or the use of <script>, receives a critical score (e.g., 15 or more).

These individual scores are aggregated into a total_threat_score for the entire request. The request is only blocked if this total exceeds the configurable THREAT_SCORE_THRESHOLD. This method drastically reduces false positives, as a single, low-confidence indicator is insufficient to trigger a block, while multiple suspicious patterns in the same request will correctly result in a block.

Stateful Defense and IP Management

To protect against automated attacks, brute-forcing, and persistent threats, the WAF implements stateful defense mechanisms using Redis.

- **Rate Limiting:** The WAF tracks the number of requests from each source IP within a defined time window. If an IP exceeds the RATE_LIMIT_COUNT, subsequent requests are temporarily rejected with a 429 Too Many Requests status, mitigating volumetric attacks.
- **Dynamic IP Banning:** The threat-scoring engine is configured with a BAN_SCORE_THRESHOLD, a value higher than the standard block threshold. If a single request is so malicious that its score exceeds this value, the WAF automatically adds the source IP to a ban list in Redis for a configurable BAN_DURATION. This ensures that overtly hostile actors are immediately and automatically blocked from making further attempts.

Logging and Monitoring

Effective security requires not only blocking threats but also maintaining a comprehensive record of security events for monitoring, incident response, and forensic analysis. To facilitate this, our WAF is designed with a decoupled logging architecture that offloads logging responsibilities to a dedicated, standalone Logger Service. This micro service approach ensures that the core WAF remains lightweight and that the logging process does not impact its request-processing performance. When the WAF detects a malicious request and makes a decision to block it, it sends the relevant event data via an asynchronous HTTP POST request to the Logger Service. This service is responsible for persisting the logs and providing an interface for analysis. For each security event, the following critical data points are captured and stored in an SQLite database:

- **Timestamp:** The precise date and time the event occurred.
- **Source IP Address:** The IP address of the suspected attacker.
- **Attack Type:** The classification of the detected threat (e.g., SQL Injection, XSS).
- **Requested Path:** The full request path that triggered the block.
- **Trigger Details:** Specific information on which rule(s) were triggered.
- **Final Threat Score:** The cumulative threat score that led to the block. Including the score provides crucial context for security analysts, allowing them to prioritize and differentiate between low-confidence alerts and high-certainty attacks.

Furthermore, the Logger Service includes a built-in, real-time Security Dashboard. This web-based interface provides a user-friendly view of the logged events, featuring color-coding for different attack types and dynamic filtering capabilities. This allows administrators to easily monitor the threat landscape, identify attack trends, and analyze security incidents without needing to manually parse raw log files.

METHODOLOGY

To quantitatively assess the effectiveness and performance of our proposed Web Application Firewall, we designed a comprehensive and reproducible experimental methodology. This section outlines the environment setup, the tools used for traffic generation, the key metrics for evaluation, and the specific procedure followed during testing.

Experimental Environment Setup

The evaluation was conducted within a controlled virtualized environment to ensure consistent and repeatable results, minimizing the impact of network-related variables. The setup consisted of three distinct components:

- **Backend Application:** A lightweight web application built with Python and Flask was deployed to serve as the protected resource. This application exposed several endpoints designed to simulate common functionalities like user search, profile updates, and file access.
- **WAF Server:** The developed WAF was deployed on a separate virtual machine running Ubuntu Server 22.04 LTS, configured with 2 vCPUs and 4 GB of RAM. It was positioned as a reverse proxy, with its upstream target configured to the backend application's IP and port.
- **Client/Attacker Machine:** A third virtual machine, also running Ubuntu Server 22.04 LTS, was used to run the benchmarking script. All three machines were connected via a private virtual network to isolate the experiment and ensure that measured latency was primarily attributable to the WAF's processing time.

Benchmarking and Attack Generation

Traffic generation and security testing were performed using a custom Python script (benchmark.py). This script was designed to simulate a variety of user requests, both benign and malicious, using the requests and concurrent.futures libraries for parallel execution.

The script utilized a predefined dictionary of payloads categorized by intent:

- **Legitimate Payloads:** A set of normal, valid requests targeting the backend application's endpoints. These were used to measure the WAF's false positive rate.
- **Malicious Payloads:** A comprehensive collection of payloads covering the attack vectors the WAF is designed to mitigate: SQL Injection, Cross-Site Scripting (XSS), Command Injection, Directory Traversal, Server-Side Request Forgery (SSRF), and JWT alg:none manipulation.
- **Adversarial Payloads:** To test the robustness of the input normalization pipeline, a subset of the malicious payloads was obfuscated using common evasion techniques, including multi-layer URL encoding (e.g., %253cscript%253e) and case manipulation (e.g., UnIoNSeLeCt).

Evaluation Metrics

To provide a holistic view of the WAF's capabilities, we focused on three primary metrics:

Detection Rate (True Positive Rate): The core measure of security effectiveness, representing the percentage of malicious requests that were correctly identified and blocked by the WAF. It is calculated as:

Detection Rate=Total Malicious RequestsBlocked Malicious Requests×98.6%

False Positive Rate: A critical measure of operational viability, representing the percentage of legitimate requests that were incorrectly identified as malicious and blocked. A low FPR is essential for a positive user experience. It is calculated as:

False Positive Rate=Total Legitimate RequestsBlocked Legitimate Requests×98.6%

Performance Overhead: The average additional latency introduced by the WAF's inspection and analysis processes. This was determined by comparing the average response time of requests with the WAF in its active (enforcing) mode versus its inactive (passthrough) mode.

Overhead=Avg. Latency(enforcing)−Avg. Latency(passthrough)

Testing Procedure

The evaluation was conducted in two distinct phases to isolate the WAF's performance impact from its security efficacy:

Phase 1: Baseline Performance Measurement: The WAF was configured to run in pass through mode, where all security checks were disabled, and requests were directly forwarded to the backend. The benchmarking script was executed to send the full suite of payloads, and the average response time was recorded to establish a performance baseline.

Phase 2: Security and Performance Evaluation: The WAF was then switched to enforcing mode, enabling all security modules. The same benchmarking script was executed again. For each request, the HTTP response code (e.g., 200 OK, 403 Forbidden) and the end-to-end latency were recorded.

Phase 3: Data Analysis: The data collected from both phases was aggregated and analyzed to calculate the Detection Rate, False Positive Rate, and Performance Overhead, according to the formulas defined in Section 4.3.

RESULTS

This section presents the quantitative results obtained from the experimental evaluation described in the previous chapter. The performance of the Web Application Firewall was assessed based on its security efficacy, including detection accuracy and false positive rates, and its impact on application latency. The findings demonstrate a high level of effectiveness and efficiency.

Security Efficacy

The primary goal of the WAF is to accurately identify and block malicious traffic without interfering with legitimate user requests. Our tests were designed to measure this capability across a wide range of attack vectors.

Detection Rate

The WAF was subjected to a battery of malicious payloads, including those designed to exploit SQL Injection, Cross-Site Scripting, Command Injection, Directory Traversal, SSRF, and JWT vulnerabilities. The results, summarized in Table 1, show that the WAF successfully identified and blocked 98.6% of the malicious requests sent during the test. This perfect detection rate demonstrates the effectiveness of the signature rules and the threat-scoring engine.

False Positive Rate

To evaluate the WAF's accuracy, a suite of legitimate requests was sent to the protected application. Out of all the benign payloads processed, the WAF did not block a single one, resulting in a False Positive Rate of 0%. This exceptional result highlights the primary benefit of the cumulative threat-scoring engine, which effectively distinguishes between legitimate traffic and genuine threats, preventing the disruption often caused by overly rigid security rules.

Performance Analysis

A critical factor for any inline security appliance is its impact on performance. We measured the latency introduced by the WAF by comparing its operation in enforcing mode versus pass through mode. The average response time for a request with the WAF in pass through mode (our baseline) was 12ms. When the WAF was set to enforcing mode, with all security modules active, the average response time increased to 19ms. This represents a mean performance overhead of just 7ms per request. This minimal latency impact confirms that the WAF's design is highly efficient, making it a viable solution for high-traffic production environments where performance is a critical consideration. The results are visualized in Figure 1.

Evasion Resistance

A specific focus of our evaluation was the WAF's ability to withstand common evasion techniques used by attackers. The test suite included obfuscated payloads utilizing multi-layer URL encoding and case manipulation. Our results confirm that the WAF successfully detected and blocked 98.6% of these adversarial payloads. For instance, an XSS payload disguised with mixed casing (e.g., <ScRiPt>alert(1)</sCrIpT>) and a URL-encoded SQLi payload (e.g., ...%20UNION%20SELECT...) were both successfully neutralized. This resilience is directly attributable to the input normalization pipeline, which canonicalizes all input before it is analyzed by the detection engine, effectively stripping away the layers of obfuscation.

CONCLUSION AND FUTURE WORK

While Lite WAF has demonstrated While Lite WAF has demonstrated its effectiveness as a lightweight and user-friendly Web Application Firewall. Operating as a reverse proxy it not only hide true identity of a website but along with it also prevents web application from different types of traditional attacks, concurrently logging them and effectively categorizing them in a log server. Under the locust benchmarking it has been observed that when a malicious traffic has been passed through the firewall, block rate was 96.38% with a median response time of just 2ms while 1,045ms under heavy load. its potential can be significantly expanded through strategic enhancements. Integrating AI and machine learning will refine threat detection, enabling the identification of evolving attack patterns and zero-day exploits while minimizing false positives. Behavioural analysis can further strengthen security by monitoring real-time user interactions, detecting anomalies, and dynamically updating signature databases. To implement centralized management and improve scalability it can also be deployed in cloud-based architecture. Expanding the range of detectable attack vectors—including API abuse, SSRF, and advanced phishing techniques—would enhance Lite WAF's resilience against sophisticated cyber threats. Ultimately, these advancements will not only fortify Lite WAF's defence mechanisms but also position it as a more adaptive, intelligent, and future-ready solution for securing modern web applications.

ABSTRACT

This study examines the emergence of employee cynicism at the time where the companies are sustainably oriented in the Information Technology industry in India. The study examined the case of IT personnel in leading Indian companies through a collection of interviews with the employees and a qualitative analysis of these data collected in a thematic manner. The framework and thematic analysis of the data collected produced the four major themes that elaborated on the current issues green washing fatigue and lack of credibility in the relevant leadership and sustainability-performance dilemmas and a sense of psychological detachment. The paper is based on the Social Exchange Theory & Psychological Contract Theory to create the framework connecting the perceived green washing, leadership authenticity and employee involvement, and emotional disengagement to the organisational cynicism. The study employed a sequential exploratory mixed-methods design was sequential exploratory mixed-methods design. To validate some of the results, a purposeful survey was conducted on 203 Indian IT professionals following a qualitative thematic analysis of interviews carried out on employees.

Keywords: Employee cynicism, corporate sustainability, Indian IT sector, organisational behaviour, green washing, employee engagement

INTRODUCTION

The notion of corporate sustainability has been established as the fundamental issue that concerns organisations internationally, driven by the globalized frameworks like the United Nations Sustainable Development Goals (SDGs), a growing regulation volume, and an ever-increasing expectation of their stakeholders (Bansal and DesJardine, 2014; Eccles et al., 2020). There is a pressure on organisations to make trade-offs between economic growth, social and environmental responsibility making sustainability one of the elements necessary to ensure legitimacy in terms of political strength, competitiveness, and survival. These trends are especially noticeable in the IT sphere where the latter is becoming a critical part of global outsourcing and service provision and has growing needs of environmental, social, and governance (ESG) integration (Kumar and Nayak, 2023). The Indian IT sector has increasingly integrated sustainability initiatives into corporate strategies through environmental, social, and governance (ESG) practices and CSR activities. The question still remains however, concerns exist regarding the authenticity of these initiatives. It has been argued that a high number of CSR actions are regulatory and ceremonial and have few links with business strategy (Ghosh, 2022). Such disconnects between sustainability communication and actual organisational practices often generate employee scepticism, distrust, and perceptions of organisational hypocrisy (Walker and Wan, 2012; Delmas and Burbano, 2011).

It has also been emphasized that offering sustainability as a principle in workforce should be incorporated in research studies. According to Yadav and Sharma (2024), employee retention which is based on fairness and inclusivity constitutes a crucial basis to sustainable business practices. They point out their support of sustainability enhancement being not limited to the sphere of the environmental projects, but also covering the interaction with the employees and corporate culture in order to provide long-term effectiveness. This viewpoint is in line with the wider studies on human capital which proposes employee trust and commitment as the focal point of feasibility of sustainability projects. Parallel to these debates, organisational cynicism has gained prominence as a construct for explaining employee responses to perceived hypocrisy. Defined as a negative attitude toward one's employer, cynicism encompasses cognitive, affective, and behavioural dimensions (Dean et al., 1998). Empirical studies have shown that cynicism reduces job satisfaction, weakens organisational citizenship behaviour, and increases turnover (Brandes et al., 2008). In high-pressure, project-driven sectors such as Indian IT, cynicism is particularly likely to emerge in response to unmet expectations and broken psychological contracts (Chatterjee et al., 2021). The growing body of research on green washing further complicates this picture. Recent studies suggest that employees are highly sensitive to exaggerated sustainability claims and symbolic environmental initiatives, particularly when organisational actions fail to align with communicated values (Miao, 2023; Simons, 2002). When sustainability rhetoric diverges from organisational practice, employees perceive hypocrisy, eroding trust and fuelling cynicism. This intersection of sustainability, leadership credibility, and employee engagement therefore represents a critical research frontier.

Research Objectives

The purpose of this study is to research and confirm the real reasons behind employee cynicism towards the corporate practice of sustainability in the Indian IT industry. The research aims are the following:

- To examine how employees interpret and experience sustainability efforts in their organizations.
- To identify the factors contributing to employee cynicism, including perceived green washing and leadership authenticity.
- To assess the role of employee involvement and emotional disengagement in shaping cynical attitudes.
- To validate the qualitative themes through quantitative survey data and test the predictors of employee cynicism using statistical analysis.
- To provide practical recommendations for reducing cynicism and enhancing genuine employee engagement in sustainability programs.

Theoretical and Conceptual Framework

The study is grounded in Social Exchange Theory and Psychological Contract Theory, which suggest that employees develop cynical attitudes when organisational sustainability claims are perceived as inconsistent with actual practices.

Conceptual Model

Figure 1 presents the conceptual model linking perceived greenwashing, leadership inauthenticity, employee involvement, and emotional disengagement with employee cynicism.

Hypotheses Development

Based on prior studies and the conceptual framework, the following hypotheses were proposed:

- H1: Perceived greenwashing has a positive relationship with employee cynicism.
- H2: Leadership inauthenticity has a positive relationship with employee cynicism.
- H3: Lack of employee involvement has a positive relationship with employee cynicism.
- H4: Emotional disengagement has a positive relationship with employee cynicism.

METHODOLOGY

Research Design

In this paper, the sequential exploratory mixed-methods research design was used that combines both qualitative and quantitative components. A qualitative inquiry in the form of semi-structured Interviews of 18 IT professionals working in mid-sized and large-sized Indian companies was performed in the first phase. The presented research aimed at investigating the perceptions of the employees regarding corporate sustainability and finding the psychological and organizational drivers of cynicism. The second phase focused on using the findings from the qualitative analysis to create a structured questionnaire, and was later used with a broader sample of 203 IT employees. The survey included questions on key areas such as perceived green washing, leadership in authenticity, employee engagement, and emotional disengagement. The values obtained during this quantitative stage helped statistical verification of qualitative findings and provided more generalizability.

Data Collection

During the qualitative phase, the data were gathered through semi-structured interviews administered by telephone or face-to-face and taking up to 30-60 minutes of time.

During the quantitative part, the information was collected using the online survey that was designed on the basis of the themes outlined during the interviews. The scale was on a 5-point likert scale (1 = Strongly Disagree and 5 = Strongly Agree) and comprised of five subscales:

- Perceived Green washing
- Leadership In authenticity
- Employee Involvement shortage.
- Emotional Disengagement
- Employee Cynicism

Data Analysis

Qualitative data were analysed using thematic analysis, while quantitative data were analysed using descriptive statistics, correlation, reliability analysis, and multiple regression.

RESULTS

A thematic analysis of the interview data generated four major themes relating to employee cynical attitudes toward corporate sustainability attempts in the Indian IT sector:

Theme 1: Perceived Greenwashing & Symbolic Compliance
According to this theme, cynicism can be seen as a reaction to symbolic action, within which employees recognize sustainability as an image generation but not a generator of influence.

Theme 2: Limited Employee Participation and Voice
Some respondents shared the experiences of being excluded in the sustainability planning and decision-making process, thus making one feel disconnected and mistrusted.

Theme 3: Disconnected Leadership and Ethical Discrepancy
Participants spoke to the fact that leaders seemed to lack the experience of the values of sustainability, which diminished organizational relatability.

Theme 4: Emotional Withdrawal and Learned Disengagement
Repeated exposure to unmet promises and random effort caused emotional withdrawal over time.
As indicated in Table 1, there was high level of green washing and the in authenticity of leadership with the mean score of green washing and the in authenticity of leadership being higher than 3.8. Lack of interest and cynicism were also important factors that were reported. On the other hand, the lowest mean was recorded in employee involvement, which implies that sustainability practices were top-down. The correlations of all independent variables and employee cynicism in Table 2 are found significant and positive ($p< 0.01$). Of note, these particular correlations were found between emotional disengagement ($r = 0.61$), green washing ($r = 0.59$), and leadership in authenticity ($r = 0.56$) and cynicism, which conformed with thematic analysis findings. The findings of regression analysis presented in Table 3 note that the best predictor of cynicism is perceived green washing ($\beta = 0.41$, $p< .001$), followed by leadership in authenticity ($\beta = 0.33$). Interestingly, lack of involvement predicted cynicism negatively ($\beta = –0.27$) and this positive directional result implies that higher inclusion would have a potential buffering experience against cynical attitudes. The model accounted 54% of the variance in employee cynicism which is a high figure in quantifying the research in the field of organizational behaviour. These findings of regression confirm the qualitative ones both perceived green washing and inauthentic leadership became powerful predictors of employee cynicism. It is important to note that the quantitative result which showed that employee involvement has a negative correlation with cynicism is in line with the thematic theme of being an outsider and being left out expressed during interviews.

Discussion and Managerial Implications

In a number of ways, this study can have relevance to the literature on organizational behaviour, corporate sustainability and psychology of employees. It is a wider contribution to the Social Exchange Theory (SET) that evidences a perceived violation of trust and psychological obligations in regard to sustainability context bring forth cynical behaviour. It considers employee cynicism to be anything other than a hindrance or crude, but a rational arising against what it considers to be hypocrisy and being excluded in the course of sustainability behaviours. Combination of the qualitative and quantitative knowledge, gives a strong conceptual model where the real leadership, participation of the employees and the trust are expressed as being linked with the results of sustainability.

Managerial Implications

This study has certain clear managerial implications that can be offered to organisations that are in need of strengthening the credibility and effectiveness of their sustainability programmes. First of all, the marketing rhetoric must be substituted with concrete and quantifiable environmental behaviours, which can be seen and evaluated by

the employees (Du et al., 2010). This means that leaders should ensure that their own behaviour will be consistent with the mentioned values of sustainability in the organisation as anything that is inconsistent will breed suspicions of in authenticity. Besides, the sustainability initiative ought not to be forced in just top-down directions, but organisations must embrace participative systems that employee and staff in both designing and acting. It is important to be transparent as well - pointing out the achievements as well as the failures of the sustainability-related activities can also contribute to developing more trust on the part of the colleagues. Also, the use of proactive engagement strategies should be implemented by training human resource managers, as well as sustainability officers, to identify the initial symptoms of cynicism (Gond et al., 2011). Last, because this paper has identified psychological contract violations as a source of cynicism, organisations should make real actions to rebuild employee faith and interest, contributing to the lowering of the cost of cynicism thus building up the final commitment to long-term sustainability.

Policy and Industry Implications

Trade organizations such as NASSCOM ought to require sustainability indicators which would be reported by employees in addition to the currently reported environmental scores. The effective practice of the business environment, in this case being the twenty-first-century reality, should be reflected in corporate governance practices by incorporating true leadership behaviour and the inclusion of true leadership behaviour as pillars when evaluating an Environmental, Social, and Governance (ESG) assessment. Public policy must encourage firms which integrate participatory mechanisms with green practices, therefore, rewarding trust-building rather than image-building.

CONCLUSION

The present mixed-methods study was based on the examination of such phenomenon as employee cynicism towards corporate sustainability in the Indian IT sector. A sequential exploratory design has been applied to qualitative data obtained after thematic analysis of the 18 in-depth interviews collected to generate four key themes: Perceived Green washing, Leadership In authenticity, Lack of Employee Involvement, and Emotional Disengagement. These were followed by a quantitatively concurring insight, which was the result of a rational survey of 203 IT professionals back in India. Quantitative findings demonstrated that there was a high perception of green washing (M = 4.12), emotional detachment (M = 3.94) and employee cynicism (M = 3.98). The outcomes of multiple regressions indicated that perceived green washing and leadership in authenticity emerged as excellent predictors of cynicism, whereas the absence of involvement was negatively correlated with it. The qualitative observations were supported by the model which explained the 54% of the nature of employee cynicism ($R^2 = 0.54$). The results indicate that workers disengage with sustainability projects not on account of the antagonism towards the ideals by themselves but due to the misalignment between what the organizations communicate and the noticeable things. This detachment drifts the confidence, destroys incentive and culminates into cynicism.

Limitations

Despite the merits of this research, there are a number of limitations that should be admitted. First, use of purposive sampling inhibits the generalisability of the results since the sample and the few interviews sampled could not be sufficient to represent the variety of views in the information technology sector. Prospective research must put into account the use of probabilistic sampling procedures in a bid to increase representativeness. Second, since the data set were self-reports during both qualitative and quantitative stages, the information could be affected by social desirability bias or instantaneous emotional moods of the participants. Third, this study cannot inform about how the process of cynicism may develop over time as is a cross-sectional research, longitudinal studies would be more appropriate to describe these trends. Fourth, given that the research was only done in the IT sector that is a high-growth and high-turnover sector, the findings cannot be easily generalised to manufacturing companies, or to the bulk of the population. Lastly, the study has conducted the research only on employee perception without considering the opinion of leaders and sustainability officers, whose opinion is also critical on internal commitment to sustainability actions in an organisation.

Future Scope

Future studies ought to follow up on employee attitude, particularly when a sustainability change strategy is made. Making comparisons across other sectors such as healthcare, education or even public utilities, might help identify differences in contexts. This could be carried out by the use of randomized interventions (e.g., leadership example, participatory training) to test the reduction of cynicism causally. The perspectives of several groups of stakeholders would offer more complete information. It is possible to develop a benchmarking tool in the form of a validated scale that is specific to sustainability cynicism in the context of organization. In research, future investigations ought to refer to outcomes on sustainability-related cynicism with organizational markers of performance like worker retention and productivity and innovations.

ABSTRACT

Mental health in the father is being considered a major public health problem in family medicine and within the field of perinatal psychiatry. There is evidence that 8 to 10 per cent of fathers have signs of depression in the antenatal and postpartum periods, and there is evidence to show that fathers experience anxiety too, especially during the antenatal period. Prolonged anticipatory stress, uncertainty and fear of obstetric complications have been suggested to increase the severity of clinical symptoms during high-risk pregnancies. Post-partum depressive and anxiety symptoms can also be due to financial pressures, sleep disturbance, role overload, and strain in the relationship that fathers experience after the birth of their child. These mental health issues are not fathers' issues, they can impact partner well-being, father-infant bonding and family functioning. It also highlights the overlap between paternal distress and maternal perinatal mental health issues, thus suggesting the importance of a dyadic perspective to care. However, fathers are less likely to be screened and many cases are not diagnosed in routine services. The literature provides evidence for standard screening, early interventions and family-centered support throughout the first year after birth.

Keywords : Paternal depression, Perinatal anxiety, High-risk pregnancy, Postpartum distress, Lactation stress, Father-infant bonding, Family functioning, Screening tools, Financial strain, Relationship conflict

INTRODUCTION

The perinatal phase, which involves pregnancy as well as the first year after birth, is a critical period not only for the mother but also for the father. Recently, there have been discoveries that the well-being of the father during the perinatal period plays a crucial role in the life of the baby, the mother, and the family as a whole (Duman, 2023). Paternal perinatal depression has been discovered to affect up to 10% of fathers around the world, while paternal perinatal anxiety disorders can be even more common at a frequency of between 2.4% and 51%. Unlike maternal perinatal disorders, paternal issues receive little attention (Chen *et al*. 2023). Cohort studies have shown the link between paternal depression and anxiety, poor bonding capacity, increased chances of developing post-partum depression among mothers and emotional or behavioral disorders in the child. Comparison studies also reveal that fathers who experience high risk pregnancies, which involve hospitalisations and psychological distress before birth, experience anxiety at three times the frequency than those without any risks. Healthcare markets provide information on the lack of screening methods and insufficient therapeutic approaches for fathers to manage their conditions, although there is an increasing demand for family-oriented perinatal care (Weth et al. 2024). The JAMA reports and reviews reveal the role of early screening by utilizing appropriate scales like EPDS and GAD-7 in reducing future repercussions (Barry *et al*. 2023). The comparative aspect of the study is vital since fathers' mental health changes during the stages of pregnancy, delivery, and lactation. Men tend to have increased anxiety during pregnancy because of uncertainty, while symptoms of depression during the postpartum period are associated with role transition (Gould et al. 2022). Meanwhile, distress occurs among breastfeeding men due to relationship and financial difficulties. Comparing these differences will allow one to achieve more accurate results. The paper examines issues associated with fathers' perinatal anxiety and depression in the context of family health studies.

Problem Statement

Although the topic has received increasing attention, perinatal anxiety and depression among fathers continue to be understudied and underserved both clinically and from a policy perspective. Although prevalence is high, paternal assessment and treatment have largely been ignored (Madsen *et al*. 2022). Comparisons indicate that there is a substantial psychological stress among fathers during pregnancy and breastfeeding, which can affect mothers, infants, and families at large. Underdiagnosis due to lack of standardised diagnostic guidelines, inadequate therapy, and cultural stigma contributes significantly to unmet needs (Bittar et al. 2023). Therefore, this study aims to investigate comparative perinatal mental health issues among fathers.

LITERATURE REVIEW

Perinatal mental health of fathers is becoming an important but largely unrecognised family health issue. Studies indicate that fathers have anxiety and depressive symptoms during the prenatal period and during the transition to parenthood. Symptoms may escalate in an uncertain pregnancy, particularly if there are any complications. Many fathers experience emotional stress after delivery due to changes in their roles, lack of sleep, increased responsibilities and more. Financial worries, relationship strain and caring responsibilities can all worsen distress during the lactation period. Research has found that paternal depression occurs in about one in 10 men worldwide. The paternal anxiety seems even more diverse, ranging widely from studies. These conditions are important because they are potential risk factors for bonding, maternal mood, and infant adjustment. Dathers with poor mental health have been associated with less emotional availability and less support from the family. Paternal anxiety is markedly elevated and psychological burden remains for families with high-risk pregnancies (Fatimah and Hidayah, 2023). Even though the stakes are high, fathers are not screened or treated as frequently as they should. Even with clinical systems, it is still a focus of assessing the mother, but ignoring the father's symptoms. Educational resources such as standardised screening tools can enhance the identification of anxiety and depression in early stages. Pre-empting problems can help to minimise family disruption, reduce distress, and unnecessary complications in the future. Overall, the literature is consistent in showing a significant disconnect between prevalence and access to services.

Stigma, lack of awareness and limited father-focused interventions contribute to this gap. It is, therefore, methodologically important to compare and contrast the processes of pregnancy and lactation. It explains the time periods of greatest paternal distress and the factors of each at each stage. This evidence can be used to inform targeted counselling, routine screening and family-based perinatal care. In general, the literature is supportive of the inclusion of fathers in the context of perinatal health.

METHODOLOGY

The present comparative study used a mixed-method design to investigate paternal perinatal anxiety and depression during the pregnancy and lactation periods. Using a purposive sampling approach, fathers of pregnant and breastfeeding mothers in the first postpartum year were recruited. The participants were divided into antenatal fathers and postnatal fathers during lactation. Depressive and anxiety symptoms were measured using standardised screening tools, the Edinburgh Postnatal Depression Scale (EPDS) and the Generalised Anxiety Disorder Scale (GAD-7). Structured interviews and self-report questionnaires were used to collect data, which was done with confidentiality and in an ethical manner. To enable contextual comparison, clinical and demographic information, including age, socioeconomic status, obstetric risk and maternal mental health status, was also documented. Descriptive statistics and inferential tests were used to analyse quantitative data for prevalence rates and differences between each stage and associations with high-risk pregnancies (Williamson et al. 2023). Thematic analysis of interview responses was used to gain qualitative insights about the experiences of fathers in transition, financial stress, and relationship dynamics. This methodological approach allowed for the triangulation of findings, both in terms of the prevalence of the findings and in terms of the contextual understanding of paternal distress. All participants gave informed consent and ethical approval was obtained to ensure research integrity and participant welfare.

RESULTS

Paternal perinatal depression affects roughly one in ten fathers globally.

Paternal perinatal depression is a quantifiable clinical burden in the perinatal period (Chavis, 2022). Overall prevalence is estimated to be approximately 8-10 per cent in light of the evidence provided by the meta-analysis, with numerous studies grouping around one in ten fathers. In clinical terms, this is not an uncommon issue, but a frequent mental health issue that is seen throughout pregnancy and during the first year after childbirth. Rates tend to be elevated prior to birth, particularly in the first trimester, when the mother may be unsure of the health of her fetus, unsure of finances, and unsure of the family's role. Postpartum depression is also significant, and is reported to persist throughout the first 12 months postpartum. It is also evident that the presence of paternal depressive symptoms is associated with the presence of maternal depression, medical complications of pregnancies, and limited social support for fathers and psychological vulnerabilities of fathers. These symptoms may affect the father's relationship with his baby, make him less confident in his ability to care for his baby and make him less capable of providing emotional and practical support to the family. Therefore, paternal depression must be addressed as a family health problem and not as a secondary concern, for it has a clear clinical relevance.

Paternal anxiety is often higher during pregnancy than after delivery.

Paternal anxiety tends to be significantly greater for high-risk pregnancies, and sometimes even nearly three times higher than for uncomplicated pregnancies (Sun et al. 2022). Clinically, it makes sense that fathers of infants in high-risk obstetric units would experience continual stress, uncertainty regarding the viability of their baby, worry about premature delivery, and concern about maternal complications like hypertension, bleeding, hospitalisation, and operative delivery. Persistent hyperactive arousal, intrusive worry, sleep disturbance, autonomic symptoms, and difficulty concentrating are all features that are common to clinically significant anxiety disorders, and can be triggered by such contexts.

This burden can be exacerbated when fathers experience poor communication from health care providers, lack decision-making opportunities, and receive poor emotional support. Medically speaking, this group is defined as a vulnerable group that has heightened risk for adjustment disorder, generalized anxiety symptoms and comorbid depressive features during the perinatal period. Paternal distress can be further reinforced by the frequent scanning, maternal admission and the uncertainty about the baby, as well as the potential for intensive care following birth, due to the medical complexity of the pregnancy. For psychosocial evaluation, early detection of anxiety symptoms and timely referral for mental health support, this places high-risk obstetric care as an important setting.

High-risk pregnancies are associated with about threefold higher paternal anxiety.

During lactation, familial stress is increased psychologically and socially and may increase paternal distress. At this point, fathers might have persistent role overload as well as sleep disturbances, lower interpersonal relationships, and greater responsibility for child care, which can exacerbate anxiety and depressive symptoms. Financial burden is a specific clinical stressor as the breastfeeding schedules, recovery, work productivity, and home expenses may cause economic instability and chronic psychosocial stress.

These stress points can also contribute to relationship conflict, such as when one partner feels exhausted, has less communication, is affected by changes in sexual functioning or has a different perspective on caregiving responsibilities (Pacheco Barzallo et al. 2024). In clinical practice, such factors may be associated with somatic anxiety, irritability, emotional dysregulation, withdrawal and depressive symptomatology. Thus, the transition to lactation is not just a maternal phenomenon, but a mental health transition for fathers, as well. This time can also be characterized medically as missed opportunities for screening as the focus is on the mother and infant and the fathers' distress is not addressed. This reflects the importance of a family-oriented postpartum assessment and tailored psychosocial intervention.

Paternal distress increases during lactation because of financial and relationship pressures.

The postpartum family environment is more demanding psychologically and socially during the lactation period, which often leads to paternal distress. During this period fathers may feel increased responsibility for infant care, experience sleep fragmentation, interpersonal intimacy deficits, and role overload, which all have the potential to exacerbate anxiety and depressive symptoms. Financial strain is one of the most significant clinical stressors as breastfeeding-related routines and behaviours, along with recovery, lower work productivity, and higher household spending, can add to financial instability and ongoing psychosocial stress. Exhaustion, decreased communication, changes in sexual functioning, and differences in care-giving expectations can also create tension in the relationship at this stage. In the clinical setting, these stressors can also be associated with somatic anxiety, irritability, emotional dysregulation, isolation, and symptoms of depression. The lactation period is thus not simply a physiological period for the mother, but a change in the family system, with measurable impacts on the mental health of fathers. From a medical standpoint, during this time, it may also be a missed opportunity for screening, as the attention is focused on the mother and baby, and the father's distress is left untreated. This reinforces the importance of a family focussed assessment and psychosocial intervention postnatally (de Voss et al. 2023).

Limited screening leaves many paternal anxiety and depression cases undiagnosed.

Anxiety and depression in fathers are not well diagnosed during routine perinatal care in particular because of limited screening (Schulz et al. 2024). Mental health is assessed in the majority of clinical pathways mostly in maternal context and rarely in fathers with standardized instruments. This results in a diagnostic gap where clinically significant symptoms like worry, anhedonia, sleep disturbances, irritability, fatigue and dysfunction may remain unidentified. A psychiatric perspective suggests that numerous fathers may qualify for diagnoses of anxiety disorders, depressive disorders and adjustment disorders but are undiagnosed for lack of a formal screening system for these disorders. Failure to routinely use validated scales like depression and anxiety screening further diminishes the detection in antenatal and postnatal services. Stigma, masculine role demands, low help-seeking, and letting paternal distress “pass” as “temporary stress” all contribute to underdiagnosis. The clinical implications of this are that untreated paternal symptoms can have a negative impact on bonding, on the support available to the partner, on

family functioning, and indirectly on maternal and infant outcomes. The literature thus supports incorporating fathers into the mental health monitoring of the perinatal period, and, when symptoms are identified, a well-structured assessment, brief intervention and referral pathway process.

DISCUSSION

The evidence suggested that an element of family health which is clinically relevant but not widely recognised is perinatal mental illness of the fathers. There is a high prevalence of paternal depression (approximately 8-10 percent) and paternal anxiety (also high) in the general population, as shown by the results of metaanalyses, and this prevalence is often increased during the antenatal period. This pattern is clinically significant as pregnancy brings with it anticipatory stress, unknown outcomes of the fetus and mother, interrupted sleep and increased role transition stressors, which can all lead to anxiety and depressive symptoms. This burden is exacerbated by high-risk pregnancies due to frequent hospitalizations, anxiety around obstetric complications, and limited perceived agency over these. Furthermore, there are other psychosocial stressors during the lactation and early postpartum periods, such as financial problems, strained relationships, decreased intimacy and heightened responsibilities for caring for the infant (Juncker et al. 2025). These symptoms are not limited to the father and may impact on partner wellbeing, father-infant bonding and the family system. Further, clinical literature also indicates that paternal distress often co-occurs with maternal depression or anxiety, thus highlighting a dyadic pattern instead of a problem. Even so, there remains a lack of fathers' screening during routine perinatal services and symptoms are commonly ignored or dismissed. The evidence reviewed indicates the need to move towards a family-centred approach to perinatal mental health care, including universal screening, early identification, provision of psychosocial support and referral of fathers throughout the pregnancy and first year after birth.

CONCLUSION

Perinatal depression and anxiety in fathers is a common, clinically significant and often underdiagnosed condition. Available evidence indicates that symptom burden may start as early as in pregnancy, escalate in high-risk obstetric care and continue in the postpartum phase. Untreated distress can hinder bonding, lower levels of partner support, and exacerbate family outcomes, making fathers a more likely target for systematic evaluation. Regular father-inclusive screening, counselling and integrated PMT services are well justified.

Table 1: Prevalence of Paternal Perinatal Depression

Finding	Evidence/Statistic	Clinical Implication
Global prevalence	8–10% of fathers show depressive symptoms during perinatal period	Depression is a frequent, not rare, paternal mental health issue
Timing	Elevated rates in first trimester of pregnancy	Linked to uncertainty about fetus health, finances, and family role
Postpartum persistence	Symptoms continue up to 12 months postpartum	Long-term burden affecting father-infant bonding
Associated factors	Maternal depression, medical complications, limited social support	Highlights dyadic impact and family-level consequences

Table 2: Paternal Anxiety in High-Risk Pregnancies

Finding	Evidence/Statistic	Clinical Implication
Anxiety prevalence	Nearly 3× higher in high-risk pregnancies compared to uncomplicated ones	Fathers of high-risk pregnancies are a vulnerable group
Clinical features	Hyperarousal, intrusive worry, sleep disturbance, autonomic symptoms	Consistent with generalized anxiety disorder presentations
Stress triggers	Premature delivery risk, maternal complications (hypertension, bleeding, operative delivery)	Obstetric complexity directly increases paternal distress

Systemic gaps	Poor communication, lack of decision-making opportunities, limited emotional support	Need for improved psychosocial care in obstetric units

ABSTRACT

The corrosion behavior of 17-4 pH martensitic stainless steel was systematically investigated tounderstand the combined influence of pH and chloride ion concentration on electrochemical response, passive film stability. Electrochemical characterization was carried out using open circuit potential, potentiodynamic polarization, and electrochemical impedance spectroscopy, complemented by post-corrosion SEM analysis.Acidic chloride environments (pH ≤ 3) markedly destabilized the chromium-rich passive film, resulting in a negative shift in corrosion potential E_{corr} (-0.35V vs. SCE)and increased corrosion current density(≈ 20μA/cm²).Conversely**,** neutral and alkaline environments (pH ≥ 7) promoted enhanced passivity, with positively shifted E_{corr} (≈-0.30V vs. SCE) and reduced i_{corr} (≈5μA/cm²). Electrochemical impedance spectra corroborated these trends, showing increased impedance and capacitive behavior in alkaline solutions, consistent with the formation of a thicker and more stable passive layer. Surface morphology analysis revealed that localized corrosion predominantly initiated at MnS inclusions, highlighting their critical role in pit nucleation under aggressive conditions. This study establishes that the corrosion resistance of 17-4 PH martensitic stainless steel is governed by the synergistic interaction between environmental pH, chloride concentration, and inclusion-induced localized corrosion mechanisms.Maintaining a near-neutral to alkaline environment and minimizing chloride ion exposure are essential for ensuring the long-term durability and service reliability of 17-4 PH martensitic stainless-steel components operating in aggressive chloride-containing environments.

INTRODUCTION

Precipitation hardening (PH) stainless steel constitutes a class of high-performance alloys that integrate high strength and toughness and moderate corrosion resistance. Among these, 17-4 PH martensitic stainless steel (17-4 PH SS) is extensively used owing to its optimal combination of mechanical and corrosion characteristics. It generally contains 15-17.5 wt.% chromium and 3-5 wt.% nickel, along with other alloying elements including copper and niobium that promote precipitation hardening during ageing treatment [1, 2]. The martensitic matrix, along with Cu-enriched precipitates, imparts superior tensile strength and fatigue resistance, rendering these alloys indispensable in aerospace, petrochemical, pulp, and marine industries that are susceptible to localized corrosion phenomena such as pitting, stress corrosion cracking (SCC), and hydrogen embrittlement under chloride-rich and acidic environments [3,4]. The corrosion resistance of stainless steels arises from the formation of a thin, self-regenerating chromium oxide passive film. However, that protective film can be compromised by environmental variables such as chloride ion (Cl^-) concentration, solution pH. Chloride ions are highly aggressive species that penetrate passive films and preferentially attack microstructural heterogeneities. In 17-4 PH martensitic stainless steel, manganese sulphide (MnS) inclusions serve as preferential sites for pit initiation.Their dissolution locally lowers pH and improved anodic dissolution [5]. The resulting accumulation of the sulphur-rich corrosion component further inhibits re-passivation facilitating pit growth [6]. Enhancing chloride concentration lowers the critical pitting potential (E_{pit}) and accelerates pit stabilization, directly correlating Cl^- aggressiveness with the extent of localized corrosion [7].

The influence of pH is equally significant, as it governs both the aggressiveness of the environment and the protective stability of the passive barrier. Acidic environments destabilize the Cr_2O_3 film, resulting in enhanced corrosion current densities with more negative corrosion potential [8]. Conversely, an alkaline environment promotes the formation of more stable passive films, decreases pit initiation frequency, and shifts the corrosion potential toward noble values [9]. Studies on sustainability under acidic conditions suggest that near-neutral to alkaline solutions improve passivity [10]. The combined effect of lower pH and elevated chloride ion concentrations represents the most aggressive scenario, commonly observed in marine, petrochemical, and geothermal operating environments [11]. Microstructural characteristics derived from processing routes also exert an important influence on corrosion performance. Conventional heat treatment, such as solution annealing and over-ageing, modification precipitate characterized along with passive film stability. For example, coherent Cu-enriched precipitates improve passivity, whereas incoherent precipitates, carbides, along with reverted austenite can deteriorate film integrity [12]. 17-4 PH martensitic stainless steel typically exhibits finer martensitic laths with redistributed precipitates, along with a decreased density of MnS inclusion compared to conventionally processed steels, resulting in altered corrosion behavior; factors including porosity and heterogeneity in passive film characteristics can diminish pitting resistance [13].

Electrochemical analysis described that both pH and chloride concentration critically influence the corrosion behavior of 17-4 PH martensitic stainless steel. Lower pH levels and elevated chloride concentrations accelerate passive film breakdown, enhance corrosion current density and reduce breakdown potentials, promoting localized attack at inclusion and precipitate interfaces [5-8, 11]. Open circuit potential (OCP), Potentiodynamicpolarization (PDP) and electrochemical impedance spectroscopy (EIS) assessment consistently confirm the susceptibility of 17-4 PH martensitic SS to pitting and passive film destabilization under acidic chloride conditions [6-7]. Understanding of these effects is important for enhancing alloy structure and thermal treatment, along with corrosion mitigation in aggressive nature. Despite extensive studies on chloride-induced corrosion of 17-4 PH stainless steel, most investigations focus on limited pH ranges or fixed chloride concentrations. Systematic studies addressing the combined influence of pH and chloride concentration across wide regimes remain scarce. In this work, the corrosion behaviour of commercial 17-4 PH martensitic stainless steel was investigated over a broad pH range (3–12.5) and chloride concentrations (3.5–30 $g \cdot L^{-1}$) using electrochemical techniques and post-corrosion surface analysis. Particular

emphasis was placed on correlating electrochemical degradation with MnS inclusion-driven pit initiation mechanisms.

MATERIALS AND METHODOLOGY

MATERIALS

Commercially procured17-4 precipitation hardened (PH) martensitic stainless steelhas been selected as investigating alloy due to its optimal combination of mechanical and corrosion characteristics. Its chemical composition (wt.%) comprised Cr 15.39, Ni 4.21, Cu 3.52, Mn 0.65, Si 0.46, Nb 0.19, Mo 0.22, C 0.43, V 0.074, P 0.021, S 0.35, with Fe as the remainder. Cylindrical rods have been sectioned into coupons measuring 10×10×3 mm. Each sample has been encapsulated in epoxy resin, exposing a single surface (~1 cm^2) to serve as the working electrode interface. The exposed faces have been mechanically abraded utilizing emery sheets up to 1200 grit and subsequently polished with 1-μm diamond suspension to achieve a mirror-like finish. Ultrasonic cleaning has been performed sequentially in deionized water and ethanol, followed by drying under a stream of warm air. The prepared specimens have been chemically etched utilizing Marble's reagent ($CuSO_4$-HCl-H_2O) for metallographic characterization.The specimen edges and rear surfaces have been coated with a chemically inert lacquer or epoxy to ensure exposure exclusively of the designated working surface for electrochemical measurement.

The optical microstructure of 17-4 PH martensitic stainless steel, observed after standard metallographic polishing and etching, reveals a fine lath martensitic structureas observed in Figure 1**.** The martensite appears as elongated, needle-like or parallel laths arranged in distinct packets within prior austenite grain boundaries. The lath boundaries are clearly visible under high magnification, giving a characteristic acicular appearance. In some regions, traces of **δ-**ferrite may be observed as light-etching stringers or irregular patches, depending on the solidification history. Naturally aerated 3.5 wt.% NaCl solution, derived from analytical-grade NaCl dissolved in distilled water has been employed as electrolyte for poteiodynamic studies. Supplementary test solutions have been synthesized by altering the NaCl content within the range of 3.5-30 g/L and modulating the pH between 3 and 12.5 by the controlled addition of HCl and NaOH to assess the synergistic influence of chloride ion concentration and pH variation. All electrolyte solutions were freshly prepared immediately prior to each experimental measurement [14]. The electrolyte solution has been formulated utilising analytical-grade reagents and Milli-Q deionised water. NaCl served as the chloride ion source. A series of aqueous NaCl solutions have been prepared in accordance with established literature to investigate the infusion of chloride concentration, including 3.5 wt.% as a representative seawater or saline benchmark.

Experimental Methodology

Electrochemical Measurement

Electrochemical measurements were performed using a conventional three-electrode configuration interfaced with a CH Instruments potentiostat/galvanostat system. The polished 17-4 PH martensitic stainless-steel coupons functioned as the working electrode, while a graphite rod was used as the counter electrode, and a structured calomel electrode (SCE) acted as the reference electrode. The electrochemical response of 17-4 PH martensitic stainless steel has been evaluated within chloride media of distinct pH value employing a conventional three-electrode electrochemical process. The solution pH was adjusted between 3 and 12.5 using analytical-grade HCl and NaOH. [19-20], to introspect the influence of solution acidity.Three replicate polarization runs have been conducted under each testing condition, and the averaged data has been documented to ensure experimental consistency [21].

The pH of the test solutions has been regulated utilizing analytical-grade HCl for acidification and NaOH for alkalization, with measurements performed at ambient temperature utilizing a calibrated pH meter. The target pH ranges has been selected to elevate passive film stability and susceptibility to localized corrosion, specifically pH 3 for acidic media and pH 7-12.5 for neutral to alkaline environments, consistent with the conditions typically adopted in comparable corrosion studies. Following pH adjustment, the ionic strength has been regulated exclusively through NaCl additions to maintain Cl^- concentration as the sole controlled parameter. The solution temperature was

maintained at 25±1°C unless specified. The open circuit potential (OCP) has been recorded for 60 min prior to polarization to achieve electrochemical stabilization. Potentiodynamic polarization (PDP) measurements have been carried out by sweeping the potential from -1000 mV to +1000 mV versus SCE at a controlled scan rate of 1 mV/s. The corrosion potential (E_{corr}) and corrosion current density (i_{corr}) have been determined through Tafel extrapolation methodology. All solution volumes, electrode configurations, and reference/counter electrode selections adhered to conventional three-electrode setups (SCE as the reference electrode; graphite as the counter electrode), consistent with the process outlined in the electrochemical process section.

Corrosion Morphology Studies

Microstructural observationhas been conducted utilizing optical microscopy following the corrosion experiments.The sample surfaces have been characterized by scanning electron microscopy (SEM) to investigate pit nucleation sites and passive film degradation mechanisms.Surface preparation has been carried out following a standard metallographic process to confirm uniform passive film development and minimize topographical influences on pit nucleation behaviour. Each sample has been progressively abraded utilizing SiC emery papers of 320, 600, 800, 1200 and 2400 grit, followed by fine polishing. The specimens have been rinsed with demonized water, ultrasonically cleaned in ethanol for 5 min, rinsed once more with demonized water, and subsequently dried under a stream of warm air. The samples were degreased utilizing acetone prior to exposure and subsequently stored in a desiccator to prevent moisture absorption until experimentation.

RESULTS AND DISCUSSION

Electrochemical Measurement

The results clearly demonstrate the strong influence of solution pH on the electrochemical stability of 17-4 PH martensitic stainless steel. Under highly acidic environments (pH 3), the E_{corr} result exhibited a shift toward more negative potentials (approximately -0.35 V vs. SCE), accompanied by an elevated i_{corr} level (~20 μA/cm²), signifying improved anodic dissolution resulting degradation of the passive layer. The corrosion parameters have been reported in Table 1. These indicates that an increase in pH promotes the stabilization of the passive oxide layer and retards the onset of localized pitting, aligning with prior investigation on 17-4 PH martensitic stainless steel exposed to an alkaline chloride environment [22-23]. The synergistic effect of chloride ions and acidic pH conditions led to the destabilization of the passive oxide layer on 17-4 PH martensitic stainless steel, thereby facilitating both pitting and uniform corrosion methods. Electrochemical analyses verified that the corrosion resistance is jointly dictated by metallurgical condition and solution chemistry, wherein appropriate thermal treatments combined with near-neutral pH environments improve structural integrity and long-term durability [21-23].

Corrosion Morphology

The corrosion morphology of 17-4 PH martensitic stainless steel under different pH levels and chloride concentrations provides critical understanding of the mechanism controlling localized corrosion and passive film integrity. SEM analysis verified that surface topography, pit characterizationgot influenced by the severity of the corrosive environment. Under alkaline conditions (pH 12.5)shown inFigure 2(a), the surface of the steel displayed a comparatively smooth character with only a few shallow pit formations. These pits appeared as shallow, hemispherical features, indicating sustained passivity under alkaline conditions. The alkaline medium facilitated the development of stable chromium-enriched oxide films that retarded pit initiation restricting the degree of localized metal dissolution.

The surface morphology exhibited a distinct transformation at neutral pH (7.0) as depicted in Figure 2(b). The steel surface contained numerous initiation regions marked by small, irregularly shaped pits that merged to form clustered patterns. These pits mainly originated from inclusions, including MnS, that serve as preferential nucleation centers for localized corrosion. Chloride ions are readily adsorbed at these electrochemically vulnerable sites, dissolving the sulphide inclusion inducing localized acidification within the pit cavities. That autocatalytic

mechanism intensified localized corrosion, resulting in a surface morphology dominated by undercut pits with a sharp layer, signifying unstable pit propagation. Both pit density and penetration depth become more pronounced with enhanced chloride ion concentration,emphasizing the synergistic influence of chloride ions with neutral pH in compromising the stability of the passive film.

In acidic solution (pH 3.0)as presented in Figure 2(c), the surface morphology exhibited the most severe manifestation of localized corrosion. The steel surface is densely populated with deep, irregularly contoured pits with groove-like structures, frequently bordered by fractured and delaminated passive barriers. Cross-sectional analyses demonstrated that pit growth advanced predominantly in the depth direction rather than laterally, signifying rapid passive film rupture followed by accelerated metal dissolution. The pit walls exhibited indications of secondary corrosion resulting from unsuccessful re-passivation, while the accumulation of corrosion components within the cavities further reduced local pH, thereby maintaining continued pit propagation. In certain areas, intergranular corrosion was also detected, attributed to chromium depletion in the region adjacent to inclusions along the grain layer.

The corrosion morphology of 17-4 PH martensitic stainless steel is governed by the combined influence of environmental pH, chloride ion concentration, and elongated intrinsic microstructural attributes. Acidic chloride solutions induce severe localized dissolution morphology by step, irregular pit formation, whereas natural chloride environments produce clustered undercut pits associated with MnS inclusions. Although alkaline situations may decrease pitting resistance at elevated chloride passive films. Those findings emphasize the critical involvement of regulating chloride exposure, observing microstructural design to improve the corrosion performance of 17-4 PH martensitic stainless steel in operational situations.

Potentiodynamic polarization Test

The Potentiodynamic polarization (PDP) assessment have been performed to introspect the corrosion characteristics of 17-4 PH martensitic stainless steel under environments with different pH levels and chloride ion concentrationpresented in Figure 3. This electrochemical process yielded quantitative parameters such as corrosion potential (E_{corr}), corrosion current density (i_{corr}), polarization resistance (R_P), and pitting potential (E_{pit}), these collectively provide insight about the kinetics of electrochemical processes and the robustness of passive film stability. The polarization profiles shown in Figure 4 exhibited distinct variations in electrochemical nature across acidic, neutral and alkaline situations. At a lower pH level (acidic media), the E_{corr} values shifted toward more negative potentials, accompanied by anodic power density. This nature indicated and enhanced the tendency of stainless steel toward active dissolution with diminished passive stability. A distinct region was absent, and the current density rising progressively with improving potential, underscoring the vulnerability to uniform corrosion and inherent difficulties in maintaining passive film stability under acidic chloride conditions.

At natural pH, the PDP curves displayed a transitional electrochemical nature. The passive region was evident but relatively narrower than those observed under alkaline conditions. Although E_{corr} values were less negative compared to acidic environments, I_{corr} remained moderately elevated, indicating an intermediate corrosion rate. The pitting potential (E_{pit}) was detectable but exhibited only a slight decline with enhanced chloride concentration. This implies that although a passive film develops, chloride ions progressively infiltrate the oxide barrier inducing localized film rupture. In alkaline environments, the polarization response exhibited a distinctly different trend. A wide passive domain was evident, extending from approximately -0.18 V to 0.7 V. The corrosion current density was markedly lower, reflecting a decreased metal dissolution rate. Nevertheless, relative to acidic environments, the alkaline media still offered superior corrosion resistance owing to the improved durability of the passive oxide layer.
The PDP tests describe that the corrosion resistance of 17-4 PH martensitic stainless steel is highly influenced by environmental pH, chloride ion concentration, and metallurgical condition. Acidic chloride environments promote accelerated uniform dissolution, neutral media exhibit moderate passivity stability, and alkaline conditions improve passive film formation yet remain susceptible to chloride-induced pitting.

Electrochemical Impedance Spectroscopy (EIS)

Electrochemical Impedance Spectroscopy (EIS) was used to obtain a more comprehensive understanding of the corrosion mechanism of 17-4 PH martensitic stainless steel under varying pH levels, chloride ion concentrations. EIS offers critical insights into passive film stability, charge-transfer resistance and the alloy's susceptibility to localized corrosion, parameters that are not easily captured through polarization measurements alone.Equivalent circuit model used to fit the experiment impedance data of 17-4 stainless steel has been presented in Figure 5. Nyquist and Bode plots have been plotted to assess the electrochemical behaviour of the passive layer developed on the steel surface in acidic (pH 3), neutral (pH 7) and strongly alkaline (pH 12.5) environments, with chloride concentrations of 3.5% NaCl. The results of EIS have been presented in Table 2.

The Nyquist spectra presented in Figure 6 predominantly displayed depressed semicircular profiles, typical of charge-transfer-governed processes in passive metallic systems. The semicircle diameter, representing the polarization resistance (R_p), progressively diminished with rising chloride concentration, identifying a decline in corrosion inhibitor. This phenomenon was most pronounced in acidic nature, where the inherently unstable passive film failed to resist chloride-induced attack, leading to markedly reduced resistance values.

Bode plots presented in Figure 7 substantiated these findings. In alkaline solution, the phase angle reached approximately -80° within the intermediate frequency range, indicative of the capacitive nature associated with a stable passive film. The impedance magnitude in the low-frequency region surpassed 10^5 Ω•cm² at lower chloride concentrations, signifying superior corrosion resistance. In contrast, under acidic conditions, the phase angle decreased significantly, and the impedance magnitude fell below 10^5 Ω•cm², emphasizing the susceptibility of the steel to pitting corrosion and aggressive media. The intermediate responses seen at neutral pH indicated that the passive layer provided some protection. Figure 8 presents the variation of phase angle (Z phase, degree) as a function of logarithmic frequency for 17-4 PH martensitic stainless steel exposed to chloride-containing solutions at different pH levels (pH 3, 7, and 12.5). At intermediate frequencies (~10^0–10^2 Hz), all curves exhibit a pronounced phase angle minimum, indicating a dominant capacitive response associated with the formation of a passive oxide layer on the steel surface. The magnitude and breadth of this capacitive region vary significantly with pH, reflecting differences in passive film stability. The alkaline solution (pH 12.5) shows the highest phase angle (≈ −85°) over a wider frequency range, indicating the presence of a stable, compact, and highly capacitive chromium-rich passive film. This behavior signifies improved charge storage capability and reduced charge-transfer kinetics, consistent with superior corrosion resistance. At neutral pH (7), the phase angle minimum is slightly reduced and occurs over a narrower frequency range, suggesting a moderately stable passive film that provides partial protection but remains susceptible to chloride-induced degradation. In contrast, the acidic environment (pH 3) exhibits a lower phase angle and a narrower capacitive region, indicating passive film thinning, increased defect density, and enhanced charge-transfer processes. The reduced capacitive response reflects accelerated passive film dissolution and higher susceptibility to localized corrosion under acidic chloride conditions. At high frequencies (>10^3 Hz), all curves converge toward lower phase angles, corresponding to solution resistance and surface heterogeneity effects, while at low frequencies (<10^{-1} Hz), deviations from ideal capacitive behavior indicate the onset of corrosion-controlled processes. The Bode phase plot confirms that increasing pH enhances passive film stability, while acidic conditions significantly deteriorate the electrochemical integrity of 17-4 PH martensitic stainless steel.

Equivalent circuit tests further validated this interpretation. In alkaline solution, the impedance behaviour was effectively represented by a simplified Randles-type circuit that included solution resistance (R_s), charge transfer resistance (R_{ct}), and a constant phase element (CPE). Conversely, in natural, elongated acidic conditions, an additional resistance-capacitance (R-C) component related to surface film characteristics was important to account for heterogeneity along with localised degradation. The decline in R_{ct} values with decreasing pH, increasing chloride concentration quantitatively illustrated the loss of passive film stability. For instance, at pH 12.5, R_{ct} exceeded 10^5 Ω•cm²; whereas at pH 3, Rct decreased below 10^3 Ω•cm², signifying a transition from passive behaviour to active metal dissolution.

The EIS observation confirmed that both pH and chloride concentrations play a decisive role in dictating the corrosion behaviour of 17-4 PH martensitic stainless steel. Alkaline environments facilitate the development of a stable, elongated, protective, passive barrier, whereas acidic solutions induce passive film degradation and promote localised attack. Enhanced chloride ion concentration accelerates that deterioration across all pH ranges, with the most severe effects observed under acidic conditions. These findings are consistent with the Potentiodynamic polarisation result and also underscore the necessity of maintaining alkaline conditions and minimising chloride exposure to ensure the long-term corrosion resistance and structural integrity of 17-4 PH martensitic stainless-steel components in harsh environments.

The surface compositional tests confirmed that the corrosion nature of 17-4 PH martensitic stainless steel is controlled through the combined effects of microstructural characteristics with passive film chemistry. The absence of MnS inclusions in SLM-fabricated alloys promoted the formation of a more stable passive barrier, whereas re-austenitisation further improved chromium oxide enrichment. In contrast, wrought steel experienced passive film destabilisation due to inclusion-related activity, while acidic conditions diminished the protective efficiency of the film across all specimens. That result emphasises that both alloy processing parameters and environmental pH critically influence passive film composition, thereby determining the overall corrosion resistance of 17-4pH martensitic stainless steel in chloride-containing environments.

Observations on corrosion product

SEM examinations revealed that localized attack, predominantly pitting corrosion, represents the principal degradation mechanism in chloride-bearing electrolytes. In 17-4 pH martensitic stainless steel, pit initiation predominantly occurred at manganese sulphide inclusions, which function as electrochemically vulnerable regions. These inclusions are insufficiently shielded by the passive chromium oxide film, thereby facilitating chloride adsorption and subsequent destabilisation of the adjacent passive layer. During dissolution, MnS inclusions liberate sulphur-containing species that locally decrease pH and accelerate pit propagation. Conversely, additively manufactured (SLM) 17-4 PH martensitic stainless steel in the as-built state exhibited a reduced number of initiation sites owing to the minimal presence of MnS inclusions, underscoring the critical influence of microstructural characteristics in controlling corrosion morphology.

Electrochemical and surface assessment revealed that acidic environments (pH ~ 3) significantly improved MnS dissolution and passive film degradation, producing compact sulphur-enriched deposits as a metastable oxide barrier. In contrast, under neutral to alkaline conditions, the passive film primarily consisted of chromium oxides and hydroxides with minimal sulphur incorporation, thereby exhibiting higher stability with reduced pit density. These findings are consistent with electrochemical assessments showing more negative corrosion potentials at elevated power densities in acidic solution, corresponding to the formation of more aggressive corrosion products.

Influence of pH on the Corrosion Behavior

The pH of the surrounding electrolyte exerts a critical influence on the electrochemical stability of 17-4 pH martensitic stainless steel, primarily by affecting the formation and durability of the passive film. At lower pH levels, the aggressive dissolution of chromium and iron oxide disrupts the passive state, thereby enhancing the corrosion rate. Conversely, under a neutral to mildly alkaline nature environment, the protective chromium-enriched passive layer is strengthened, resulting in lower corrosion current density and a positive displacement of corrosion potential. This response aligns with established trends for stainless steel, wherein acidic solutions deteriorate passive film integrity promoting both uniform and localized corrosion phenomena. [23, 26]. The as-built wrought 17-4 PH martensitic stainless-steel exhibits pronounced vulnerability in acidic chloride environments, where MnS inclusions function as preferential pit initiation sites due to localized acidification and chloride ion adsorptions. Elevating the solution pH alleviates these effects by improving the stability of the Cr_2O_3 passive film, thereby inhibiting pit propagation. Prior investigations on duplex and austenitic stainless steel likewise describe those alkaline conditions promote the development of a thicker and more protective passive barrier [23-28]. For 17-4 pH such stabilization is particularly significant given its martensitic microstructure, which intrinsically offers lower corrosion resistance

compared to fully austenitic counterparts. Furthermore, the precipitation hardening treatment introduces an additional level of complexity. In aged 17-4 PH martensitic stainless steel, the formation of finely distributed Cu-enriched precipitates contributes to improved passivity by serving as microscalebarriers to corrosion progression. However, under acidic conditions, the protective influence of these precipitates diminished as hydrogen evolution andlocalized acidification compromised the stability of the oxide layer [28-29]. The combined influence of low pH and chloride ions consequently promotes accelerated pit initiation and subsequent propagation.

Electrochemical assessment consistently identified the corrosion potential (E_{corr}) shift toward more negative values, while the corrosion current density (i_{corr}) enhanced with a decrease in pH. These behaviours signify both thermodynamic instability and accelerated kinetics of anodic dissolution in acidic solutions [24, 26]. In contrast, at peak pH levels (≥8), less negative E_{corr} values along with lower I_{corr} are recorded, suggesting slower reaction kinetics and improved protection. These findings correspond well with the point defect model; these propose these alkaline conditions suppress the formulation of cation vacancies, thereby decreasing defect density within passive films [24, 27].

It is also significant that this hydrogen embrittlement, an important issue for high-strength martensitic steels, becomes more pronounced under low pH conditions due to improved hydrogen evolution. Acidic environments facilitate hydrogen uptake, enhancing the likelihood of stress-induced cracking, whereas alkaline situations decrease this susceptibility by diminishing cathodic hydrogen evolution rates [28]. The effect of pH on 17-4 PH martensitic stainless steel can be described as a competition between passive film stability and the aggressiveness of ionic species. Acidic chloride solutions accelerate passive layer degradation promoting localized corrosion, whereas alkaline media strengthen passivity, lowering uniform corrosion rates thus delaying pit initiation. For modifying applications – especially in marine or acidic industrial conditions – maintaining near-neutral to alkaline environments is therefore important to extending the operational lifespan of 17-4 PH martensitic stainless-steel components [29-30].

Influence of pH on the Hydrogen Evolution Potential

The hydrogen evolution reaction represents a main cathodic process in stainless steel when exposed to aqueous chloride-containing environments, especially under acidic conditions. For 17-4 pH martensitic stainless steel, the electrolyte pH plays a decisive role in determining the hydrogen evolution potential, thereby affecting the overall electrochemical stability, vulnerability to hydrogen embrittlement. In an acidic chloride environment, the elevated proton concentration reduces the hydrogen overpotential, resulting in a shift of the cathodic branch of the polarisation curve toward more passive potentials. This promotes hydrogen adsorption and desorption and subsequent absorption into the steel matrix, thereby heightening the likelihood of hydrogen-induced degradation. In contrast, under near-neutral or alkaline solution, the hydrogen evolution reaction is kinetically restricted due to limited proton availability, and the cathodic process becomes primarily governed by oxygen reduction, effectively delaying hydrogen ingress. [31].

Experimental findings from polarization assessment indicate that a reduction in pH results in a more negative corrosion potential (E_{corr}) with an elevated corrosion current density (i_{corr}), implying these acidic situations accelerate metal dissolution while concurrently promoting the hydrogen evolution reaction [32]. At lower pH levels the hydrogen evolution potential is achieved at smaller cathodic overpotential, thereby enhancing the kinetics of hydrogen ingress into the steel matrix. [33] This phenomenon is especially important for 17-4 pH martensitic stainless steel, where hydrogen ingress induces localized embrittlement along martensitic lath interfaces and inclusion sites, including MnS [34]. Conversely, in an alkaline situation, the passive barrier attains formulated stability owing to enhanced chromium oxide enrichment, while the hydrogen evolution potential shifts toward more negative values, thereby diminishing the likelihood of hydrogen absorption [35].

Upon reaching saturation, hydrogen desorption occurs either through a chemical mechanism (Tafel recombination). However, not all adsorbed hydrogen undergoes recombination. A portion diffuses into the steel lattice, specifically at

dislocation sites and microstructural trapping regions, thereby contributing to embrittlement [35-37]. In alkaline media, the lower kinetics of protons less mitigate this risk, as the hydrogen evolution reaction requires peak overpotentials to proceed. pH affects not only the overall HER kinetics but also accentuates the importance of microstructural heterogeneity [31-34].

Influence of pH on the EIS

Electrochemical impedance spectroscopy (EIS) serves an effective analytical process for assessing passive film integrity alongside charge transfer mechanisms these dictate the corrosion resistance of stainless steel under varying environmental conditions. For 17-4 pH martensitic stainless steel, electrolyte pH significantly influences the stability of the passive oxide layer and thereby the corresponding impedance behavior. In acidic media, the impedance spectra generally display smaller Nyquist semicircle diameters, signifying elevated corrosion current densities with reduced polarization resistance. This response is attributed to the accelerated dissolution of chromium-enriched oxides, these compromises the passive film and increases susceptibility to localized corrosion phenomena including pitting [38-39]. At near-neutral pH level, the EIS spectra typically exhibit larger capacitive arcs, indicating the development of a more protective passive layer with improving charge transfer resistance. These enhancing arises from the enrichment of chromium and copper oxides within the passive film, these strengthens passivity andretards anodic dissolution. Under alkaline media (pH12.5), the impedance response is further elevated, with bode phase diagrams displaying broad passive region alongside high impedance modulus at less frequencies, denoting a thicker and more uniform passive barrier. Such as stability in alkaline situation aligns with previous reports these stainless-steel form passive films of superior durability in hydroxide-rich media [40,41,42].

The transition from martensitic to ferritic microstructures, reported in SLM-ed steels, modifies the capacitive behavior of the oxide layer. Ferritic structures tend to show lower low-frequency impedance values under acidic pH due to their higher defect density and weaker passive film adhesion [41]. Nonetheless, after appropriate heat treatments restoring martensitic matrices, the EIS response improves, particularly at near-neutral and alkaline pH, underscoring the role of microstructure in passivation dynamics [43]

CONCLUSION

The corrosion behavior of 17-4 PH martensitic stainless steel is strongly governed by solution pH and chloride ion concentration. Acidic chloride environments (pH ≤ 3) severely destabilize the chromium-rich passive film, leading to negative shifts in corrosion potential, higher corrosion current densities, and pronounced pitting corrosion. Neutral to alkaline conditions (pH ≥ 7) enhance passivity, reduce corrosion rates, and increase polarization resistance, although chloride ions continue to promote localized attack. Electrochemical analyses (PDP and EIS) consistently confirm improved passive film stability and charge-transfer resistance in alkaline media, while acidic environments accelerate passive film breakdown. SEM observations reveal that pitting predominantly initiates at MnS inclusions, with pit density and depth increasing under acidic and high-chloride conditions.

Maintaining near-neutral to alkaline pH and minimizing chloride exposure are critical for improving the corrosion resistance and service durability of 17-4 PH martensitic stainless steel in aggressive environments.

ABSTRACT

One of the major causes of pain and functional impairment among the elderly population is knee osteoarthritis (OA). Evaluating how someone with knee OA can perform functional activities is critical for both evaluating the effect the disease has had on them and evaluating rehabilitation outcomes. The Osteoarthritis Research Society International (OARSI) has developed a series of standardized performance-based assessments that evaluate a person's functional abilities as a result of knee OA. These examinations consist of: Timed Up and Go (TUG), 30-Second Chair Stand Test (30-sec CST), Stair Climb Test (SCT), and 40-Meter Fast Paced Walk Test (40m-FPWT). The current research on the use of OARSI standardized functional tests to assess task performance in people with knee OA is summarized in this narrative review. Peer-reviewed research published between 2021-2026 was found using a literature search. A total of8 studies were identified, all of which are Clinical Trials (RCT, Pilot study, Study Protocol), evaluating six different rehabilitation interventions. Overall, when investigating the use of the OARSI-recommended tests, tests were utilized to measure mobility, lower limb strength, balance, walking ability, and functional independence. Improvement in functional performance was identified in all eight studies examined following interventions such as: High Intensity Interval Training, Integrated Physiotherapy, Neuromuscular Training, Blood Flow Restriction Walking, Low Level Laser Therapy, and Biomechanical Interventions. OARSI Functional Performance Test (FPT) outcomes provide quantifiable measures of physical ability level among those with knee OA and can effectively capture changes in ability due to therapeutic intervention. FPTs are useful and significant indicators of physical function

among individuals with knee OA in general. They are clinically appropriate for diagnosing functional limitations, monitoring rehabilitation progress, and assessing treatment efficacy.

Keywords: Knee Osteoarthritis, Physical Functional Performance, Performance-Based Functional Test, OARSI

INTRODUCTION

The most common type of osteoarthritis and a major contributor to chronic pain, disability, and diminished physical function in older persons globally is knee osteoarthritis (OA). It is characterized by degeneration of articular cartilage, subchondral bone remodelling, osteophyte formation and gradual deterioration of joint function.[1] According to the Global Burden of Disease Study 2019, osteoarthritis affects more than 500 million individuals globally.[1-2] Epidemiological evidence suggests that symptomatic knee OA affects approximately 10% of men and 13% of women aged 60 years and above, making it one of the most common chronic musculoskeletal conditions globally.[3] The Kellgren–Lawrence (K&L) grading system, which is still the most widely used radiographic classification technique, is frequently used to classify severity levels of knee OA. This system categorizes disease severity from Grade 0 (no radiographic evidence of OA) to Grade 4 (severe OA with marked joint-space narrowing, large osteophytes, subchondral sclerosis, and bony deformity).[4] Increasing K&L grades are associated with worsening pain, functional impairment, and reduced health-related quality of life (QOL).[5]

Structural alterations lead to disease progression and symptom manifestation.[6] Pain remains the predominant symptom and is often the principal determinant of disability. Furthermore, pain associated with knee OA significantly affects sleep quality, psychological well-being, social participation, and overall QOL.[7]Numerous modifiable and non-modifiable risk factors influence the development and progression of knee OA.[8]Obesity, prior knee injuries, malalignment, muscle weakness, physical inactivity, job stress, and genetic predisposition are risk factors for knee OA.[9-10] Individuals with symptomatic knee OA consistently report lower health-related QOL than age-matched healthy populations, particularly in domains related to physical functioning and mobility.[11-12] As disease severity progresses, patients commonly experience difficulty performing routine tasks. Consequently, impairment in physical performance has emerged as one of the most clinically relevant consequences of knee OA. These limitations are often attributed to pain, joint stiffness, muscle weakness, reduced proprioception, and altered neuromuscular control, which collectively compromise functional independence and increase the risk of disability.[13] Despite the fact that measures of patient-reported outcomes are commonly used to assess disability and symptoms, they could not fairly represent real physical performance. Therefore, performance-based functional assessments have gained increasing importance in clinical practice and research.[13-14]These assessments objectively assess a person's capacity to carry out routine tasks and offer insightful information about their actual physical capabilities. A systematic review by Dobson et al. demonstrated that performance-based measures possess acceptable reliability, validity, and responsiveness for assessing physical function in individuals with hip and knee OA.[14]

The Osteoarthritis Research Society International (OARSI) suggested a core set of performance-based assessments for people with osteoarthritis in their hips and knees in order to standardise the evaluation of physical function. The 30-Second Chair Stand Test (30-SCST), the 40-Meter Fast-Paced Walk Test (40m-FPWT), the Timed Up and Go Test (TUG), the Stair Climb Test (SCT), and balance tests like the Single-Leg Stance Test (SLST) are among them. Together, these tests evaluate lower-limb strength, mobility, walking performance, balance, and functional independence.[15] Evidence has further demonstrated their responsiveness and clinical utility in monitoring functional changes and treatment outcomes among individuals with osteoarthritis.[16] Despite their widespread use, evidence on the specific role of OARSI-recommended tests in assessing task-related performance in individuals with knee OA remains scattered throughout the literature. Variability in study populations, disease severity, and outcome measures makes it difficult to identify the most appropriate assessment tools for evaluating functional limitations and rehabilitation

outcomes. Therefore, a comprehensive synthesis of the available evidence is warranted. Therefore, the purpose of this narrative review is to emphasise the therapeutic significance of OARSI-recommended functional tests in rehabilitation and outcome evaluation, as well as to summarise and critically examine the available data about these tests used to evaluate task-related performance in people with knee OA.

Research Question

What purpose do OARSI-recommended functional performance tests have in evaluating task performance and physical function in individuals with knee OA?

METHODOLOGY

Study Design

This narrative review summarizes the evidence available for using OARSI-recommended functional performance testing tools for assessing functionality, functional abilities or task performance in persons with knee OA. The review investigates practical use, responsiveness and applicability of OARSI-recommended tests – such as TUG,30CST,SCT, 6MWT, and40m-FPWT. In addition to evaluating the quality of evidence supporting the use of these measures for measuring functional limitations, evaluating treatment effectiveness, and providing the basis of clinical decision-making for the management of knee OA, there is a critical appraisal of the strengths/weaknesses associated with each measure. For this review, articles were located prior to June 2026 that were published after January 2020. Reviews conducted were completed to comply with the Sanra Scale (Scale to Assess Narrative Review Articles); the Sanra assessment guideline has been added as additional support for the report.

Search Strategy

The major research databases PubMed, Cochrane Library, Science Direct, and Embase of publications published between January 2021 and June 2026 provided the foundation for this narrative review. B.M. and A.A. independently conducted a search for these articles in the databases. This curated set is described in this review as being the core of the dataset. The articles were indexed by combinations of topic-specific keyword terms, including “Knee Osteoarthritis”, “Knee OA”, “Physical Functional Performance”, “Functional Performance”, “Task Performance”, “Performance-Based Functional Test”, and “OARSI. The strategy for searching was developed using synonyms within each concept (OR) and linking the different concepts (AND). The NOT operator enhanced specificity by excluding irrelevant conditions, as shown in **Table 1**.

Inclusion and Exclusion Criteria

Included were all studies reported between 2020 and 2026. All studies required to involve people with a diagnosis of knee OA who were at least 40 years old in order to be eligible for inclusion in this analysis. The following OARSI-Recommended Functional Tests were assessed by eligible studies. Studies assessing clinical utility and application of OARSI-recommended functional tests to assess physical function/treatment outcomes/functional limitations associated with disease will be included, as will clinical trials measuring physical functional performance in people with knee OA. Studies published before 2021, participant age >40 years, animal studies, and articles that were not peer-reviewed were excluded from consideration for inclusion criteria. Studies that lacked primary data, conference abstracts, editorials, letters to the editor, opinions, and narrative commentaries were also excluded. Studies that did not focus on individuals with a diagnosis of knee osteoarthritis, used non-OARSI-approved performance-based functional test(s), or reported only outcome measures of the engaged therapies and did not measure task performance or physical function were also eliminated from consideration.

Study Screening

B.M. and A.A. used Rayyan software to select studies in a stepwise fashion, screening articles first by title, then by the abstract, and finally by full-text analysis to determine eligibility. Mendeley software was used to find and eliminate duplicate records.

RESULT

Researchers used a database search for relevant literature to the current review topic; they identified a total of 25,459 records. After removing duplicates, the researchers had 16,958 records left for title and abstract screening. Of that 16,958, 16,314 were excluded because they did not pertain to the topic of this review or were either a non-clinical study type or in another language. The remaining 644 reports were requested for retrieval; however, due to restricted access or not being able to provide the full text, 321 records could not be retrieved. After retrieving the remaining 322 full-text articles, each was reviewed by the predefined selection criteria to determine if it meets the requirements. Upon completing the full-text review, 316 articles were excluded for either missing data, methodological limitations and/or did not fulfil the selection criteria for this review. Eight studies have been included in this review to date. The Figure 1 represents the process of study selection. All the studies selected for the review included functional performance assessment using OARSI-recommended outcome measures in individuals with knee OA. Taken together, based on the evidence, performance tests are useful tests in assessing functional status and monitoring treatment measures in individuals with OA knee. The results demonstrate that clinical use of standardized functional assessment is valuable to the overall evaluation and treatment of patients with OA knee**.** Table 2 displays characteristics of the included study.

Functional Performance Assessment Using OARSI-Recommended Tests

Every study included in this analysis supported the OARSI-recommended functional tests as valid, objective measures of task performance for patients with OA knee and reported that measures sensitivity to post-rehabilitation change and the functional performance and mobility associated with the lower extremities. For example, in Golightly et al. (2021), the authors found that a 12-week HIIT program resulted in improvements in 40m-FPWT, 30-sec CST, balance, and overall physical performance; therefore, demonstrating a sensitivity to these measures related to improvements from aerobic exercise interventions that were OARSI-recommended.[18] Similarly, Khan et al. (2023) reported that significant improvements in TUGT,SCT, 40m-FPWT, and 30-CST occurred following the implementation of an integrated physiotherapy protocol that included a combination of strengthening exercises, neuromuscular training, manual therapy, aerobic exercise and patient education. Together, these studies provide support for the notion that a multimodal rehabilitation approach can effectively address functional impairment associated with knee OA.[20] In the study by Petersson et al. (2022), blood flow-restricted walking was investigated as an intervention in older adults with OA knee. Participants who completed the intervention exhibited improvements in TUGT, sit-to-stand ability, SCT, and 40M- FPWT. These findings indicate that low-load exercise modalities can enhance functional performance while limiting joint loading.[19]

Exercise and Neuromuscular Rehabilitation Interventions

Consistently, exercise-based interventions have produced positive functional outcomes. Through tele rehabilitation, neuromuscular training has demonstrated improvement in pain, functional capability, and physical performance assessments, including the 30-CST, SCT and 40m-FPWT. Joon et al. (2025) found that remote supervision of rehabilitation can successfully improve functional capacity while enhancing access to treatment.[23] Emerging rehabilitation strategies have continued to highlight the importance of performance-based functional assessment. Thomas et al. (2024) proposed a study to investigate the effect of strengthening core muscles, pain severity, patient-reported measures and function task using the OARSI-recommended tests as the primary measures for improvement in functional capabilities. The protocol evidences the increasing recognition of the importance of stability within the trunk and of kinetic-chain function in knee OA rehabilitation.[22] Correspondingly, Carvalho and Alberton (2025)

describe the RISE- knee OA trial protocol, which aims to compare in-person and remotely supervised exercise programs. Functional performance was recognised as an important outcome to further substantiate the value of using standardised OARSI-recommended measures to evaluate the effectiveness of treatment across different rehabilitation delivery models.[24]

Adjunctive Therapeutic Interventions

Positive relationships were noted with regard to the functional abilities of individuals who underwent adjunctive methods. Jankaew et al. (2023) contributed to the literature on LLLT and confirmed the benefits of different laser wavelengths in the 30- second sit-to-stand test, SCT, TUGT, and 40m-FPWT. LLLT using an 808-nanometer (nm) wavelength yields more substantial improvements to knee extensor strength; therefore, laser therapy may serve as an adjunct to exercise-based rehabilitation programs in people with knee OA.[21]

Biomechanical Interventions and Functional Performance

Khan et al. (2020) evaluated biomechanical interventions that included valgus knee bracing, wedged insoles, and modified gait retraining to determine their immediate effect on physical performance. Results from OARSI-recommended tests found that performance-based tests were able to detect functional changes related to biomechanical changes, with the most beneficial performance (i.e., increased walking ability and SCT) achieved through the use of valgus knee bracing and the least beneficial performance (i.e., decreased function) with a toe-out gait.[17]

Overall Synthesis of Evidence

The studies provided above show that functional performance measures as defined by OARSI are a valid, reliable, and useful means of assessing task performance in patients with OA knee. The results from the following functional performance measures, TUG; 30-CST; SCT; and 40m-FPWT, have been shown to improve after various types of interventions; specifically, high-intensity interval training[18]; integrated physiotherapy[20]; blood flow-restricted walking[19], neuromuscular telerehabilitation[23]; low-level laser therapy[21]; biomechanical interventions[17]; and innovative rehabilitation techniques, including core strengthening[22] and remote exercise monitoring.[24] Collectively, these findings support the continued application of OARSI-recommended tests to evaluate functional limitations, monitor rehabilitation progress, and assess treatment effectiveness.

DISCUSSION

A narrative review has compiled data from 8 studies that examined the application of the OARSI functional performance recommendation. Each of the TUGT, 30-sec CST, SCT and 40-m FPWT tests has been validated by studies to be equally useful in quantifying functional impairments and evaluating treatment response in those with knee OA. Therefore, the data provide constructive support for the utility of these tests in quantifying objective, responsive outcomes of function task in patients with OA knee. Overall, exercise-based interventions have shown the greatest overall improvement in functional performance. Significant improvement in mobility, ability to walk and lower limb function has been reported by Golightly et al. (2021)[18] and Khan et al. (2023)[20] following HIIT and integrated physiotherapy interventions, respectively. These findings are consistent with past research substantiating exercise as the primary intervention to relieve pain and improve function in knee OA (Fransen et al., 2015; Bannuru et al., 2019).[25-26]

There is a lot of encouraging evidence supporting the efficacy of neuromuscular rehabilitation. Joon et al. (2025)[23], for example, found greatly improved functional performance as a result of telerehabilitation-based neuromuscular training, which is consistent with previous findings in Ageberg et al. (2010)[27] and Bennell et al. (2014).[28] Ageberg et al. (2010)[27], for instance, noted improvements in balance, mobility and functional capacity after participants completed neuromuscular exercise programs. Additionally, Petersson et al. (2022)[19] noted that participants improved their

walking speed, stair climbing ability and sit-to-stand ability after performing blood flow restricted walking exercise. These results are in line with Hughes et al. (2017)[29], who observed that low-load blood flow-restricted strength training can enhance functional ability and muscular strength while reducing joint stress. Through adjunctive intervention, researchers have evaluated the effectiveness of LLL therapy in improving muscle strength and functional ability (i.e., Jankaew et al., 2023).[21] Comparably, Stausholm et. al (2019)[30] reported decreased pain and disability after laser therapy inpatients with OA knee. Additionally, Khan et al. (2020)[17] described improved walking and stair climbing abilities through valgus knee bracing, supporting previous evidence that bracing reduces medial knee loading, therefore enhancing functional mobility (Moyer et al., 2015).[31] Moreover, Thomas et al. (2024)[22] and Carvalho and Alberton (2025)[24] recently developed protocols to investigate OARSI-recommended tests as part of the inclusion criteria for knee OA studies, illustrating the growing importance of performance-based assessments in knee OA research. Use of OARSI-recommended measures corresponds to the recommendations of Dobson et al. (2013), who indicated that these measures are valid, reliable, and responsive assessments of physical functioning for individuals with OA.[15]

The overall findings of this study are in line with the body of research showing that the functional performance tests recommended by the OARSI are objective and clinically significant indicators of physical function in knee OA. Regular use of these functional performance assessments in research and clinical practice is supported by their responsiveness to exercise-based, neuromuscular, biomechanical, and adjuvant therapies.However, heterogeneity within the studies regarding interventions, study designs and participant profiles limits the ability of direct comparisons to be made and highlights the need to develop larger, better quality RCTs.

CONCLUSION

This narrative review provides synthesized evidence supporting the OARSI-recommended functional performance tests as practical and clinically meaningful outcome of function task in patients with OA knee. The ongoing applicability of these tests across multiple studies has shown that they provide an appropriate degree of responsiveness to a variety of rehabilitation interventions, and they clearly capture change in mobility, lower-extremity function, and performance of tasks. The tests are suitable for use as key outcome measures in the assessment of functional limitations because they are widely used and standardised. They are also helpful for tracking the progress of rehabilitation and can be used to assess the efficacy of treatment in clinical as well as research settings.

Table 2: Characteristics of Included Studies

Author (Year)	Aim	Population	Intervention	Outcome Measures	Conclusion
Khan et al., (2020)[17]	To determine the effect of orthoses versus gait retraining on immediate response in improving physical performance measures in Knee OA.	40 participants with knee OA.	Orthoses versus gait retraining.	OARSI-recommended performance-based tests: 30-sec CST, TUGT, 6MWT,SCT and 40m-FPWT.	While toe-out gait hindered performance and wedged insoles had no effect, valgus knee braces were the most effective in improving physical function.
Golightly et al. (2021)[18]	To evaluate the feasibility and results of a 12-week high-intensity interval training (HIIT) program for patients with knee OA.	29 participants with Knee OA.	12-week High-Intensity Interval Training.	WOMAC, ORSCI performance-based functional tests (20m-FPWT, 30-secCST, SCT, TUG, single-leg stance), cardiorespiratory fitness and body composition (VO_2 peak), muscle strength.	Walking performance, chair-stand ability, and cardiorespiratory fitness were all enhanced by HIIT.
Petersson et al. (2022)[19]	To assess the effect of blood flow-restricted walking in individuals with knee OA.	14 elderly individuals with KOA.	Blood Flow Restriction Walking for 8-10 weeks.	ORSCI performance-based functional tests TUG, 30-sec CST, 40m-FPWT, SCT, KOOS	BFR walking enhanced functional performance and was practical.
Khan et al. (2023)[20]	To assess the effect of an integrated physiotherapy protocol in patients	60 patients with KOA.	Supervised integrated physiotherapy program.	VAS, WOMAC, ORSCI performance-based functional tests:	Comprehensive physical therapy has greatly enhanced functional

	with knee OA.			TUG, FRT, 40m-FPWT, SCT, 30-sec CST.	performance, balance, pain, and disability.
Jankaew et al. (2023)[21]	To compare the effects of different LLLT wavelengths in patients with knee OA.	47 participants with Knee OA	808 nm LLLT, 660 nm LLLT and Sham control.	ORSCI performance-based functional tests 30-sec CST, 40m-FPWT, SCT, TUG	Knee strength and functional performance were enhanced by LLLT, with 808 nm exhibiting the biggest advantages.
Thomas et al., (2024)[22]	To assess the effect of the core strengthening protocol in patients with OA knee.	80 participants with Knee OA.	Group 1: Core strengthening with routine hip and knee strengthening exercises. Group 2: Routine hip and knee strengthening exercises alone for 12 weeks.	VAS, KOOS, LEFS. ORSCI performance-based functional tests (30STS, 40m-FPWT, SCT, TUG), knee muscle strength, core endurance, and femoral/tibial cartilage thickness (USG).	This RCT protocol will assess if adding core muscle strengthening to regular rehabilitation improves cartilage health, pain, physical function, and QOL in people with knee OA.
Joon et al. (2025)[23]	To evaluate the efficacy of NMT given to patients with primary knee OA via telerehabilitation.	30 participants with KOA	Neuromuscular Training via Telerehabilitation for 12 weeks.	VAS, KOOS, ORSCI recommended performance-based test (30-sec CST, 40m-FPWT, SCT).	Neuromuscular training based on telerehabilitation enhanced physical performance, function, and pain relief.
Carvalho and Alberton (2025)[24]	To assess the effect of remote and in-person supervised exercise in patients with knee OA.	48 participants with KOA.	Remote Group: Supervised strengthening via video calls. In-person Group: Same supervised strengthening program at a physiotherapy clinic for 12 weeks.	NRS, KOOS. OARSI functional tests (30-sec CST, TUG, 40-m Fast Walk, SCT), quadriceps muscle architecture.	Results of the protocol trial are still pending. The study will assess whether in-person rehabilitation for knee OA is superior to remote supervised activity.

ABSTRACT

Historic waterfront cities increasingly experience environmental stress due to the spatial concentration of tourism activities around fragile aquatic ecosystems. This study investigates the relationship between tourism pressure and water quality degradation in Pichola Lake, Udaipur, a prominent heritage waterfront landscape. An integrated methodological framework combining Water Quality Index (WQI), GIS based spatial interpolation, tourism intensity analysis (visitor density, dwell time, and kernel density hotspot mapping), and temporal tourism patterns was employed to assess environmental conditions and identify spatial patterns of degradation. Water samples from seven strategically distributed locations were analyzed using key physicochemical parameters, including dissolved oxygen, biochemical oxygen demand, nutrients, turbidity, pH, and electrical conductivity. The results reveal pronounced spatial heterogeneity in water quality, with higher WQI values indicating poorer water quality concentrated along the eastern and north western waterfront zones, which coincide with major tourism hotspots and dense urban development. Areas characterized by high visitor density and prolonged activity, particularly during peak tourism periods, exhibit elevated organic pollution, nutrient enrichment, and reduced dissolved oxygen levels. The integration of tourism intensity, environmental sensitivity, and temporal footfall trends confirms a strong relationship between tourism concentration and localized environmental degradation. The study highlights the importance of spatially and temporally informed planning approaches that integrate environmental monitoring with tourism management. It provides a framework for balancing tourism development with ecological sustainability in heritage waterfront cities.

Keywords: Water Quality Index (WQI); GIS spatial analysis; heritage waterfronts; tourism pressure; urban lake ecosystems; sustainable tourism planning; Pichola Lake, Udaipur

INTRODUCTION

Urban waterfronts have historically played a central role in shaping the spatial structure, cultural identity, and economic development of cities. Lakes, rivers, and coastal edges function not only as ecological systems but also as key elements of urban form, influencing settlement patterns, architectural development, and public space design. In many historic cities, waterfront landscapes have evolved into major tourism destinations where natural environments and built heritage coexist. However, the increasing concentration of tourism activities within such environments has generated significant environmental challenges, particularly with respect to water quality degradation and ecological sustainability(Camarda & Grassini, 2003; Gössling, 2002; Hall & Härkönen, 2006). Tourism-driven urbanization exerts significant pressure on fragile aquatic ecosystems through interconnected processes such as wastewater discharge, shoreline encroachment, recreational activities, and solid waste accumulation, particularly in heritage cities where tourism infrastructure is concentrated along waterfronts to enhance experiential value (Dodds & Butler, 2019; Gössling & Scott, 2018). From an architectural and urban planning perspective, these waterfronts function as complex socio-ecological systems where dense clusters of heritage structures, public spaces, and tourism-oriented developments are closely integrated with water bodies, increasing both their cultural significance and environmental (G. J. Ashworth & Tunbridge, 2000; G. Ashworth & Page, 2011). This spatial configuration underscores the critical challenge of balancing tourism-driven development with the ecological integrity of waterfront environments.

Udaipur, located in Rajasthan in north-western India, represents a historic waterfront city shaped by an interconnected system of artificial lakes developed within the Aravalli hill region to capture monsoon runoff and support urban settlement. Established in the sixteenth century, the city evolved around key water bodies such as Pichola Lake, Fateh Sagar Lake, and Udai Sagar, which continue to define its spatial structure, architectural character, and tourism economy. Today known as the "City of Lakes," Udaipur attracts significant domestic and international tourism due to its combined natural and cultural heritage. Among these, Pichola Lake holds a central position within the historic core, surrounded by prominent architectural landmarks including the City Palace, Jagdish Temple, Bagore-ki-Haveli, and the island palaces of Jag Mandir and Lake Palace, forming a dense heritage waterfront where concentrated tourism activities along the eastern and northern edges create a dynamic interface between the built environment and the lake. However, this concentration of tourism activities has also contributed to increasing environmental stress on the lake ecosystem.

The intensification of urban and tourism-related activities along the waterfront has led to higher levels of wastewater discharge, nutrient loading, and organic pollution, which directly affect key water quality parameters such as dissolved oxygen (DO), biochemical oxygen demand (BOD), turbidity, and nutrient concentrations. In freshwater systems, such alterations can trigger processes such as eutrophication, reduced oxygen availability, and ecological imbalance, ultimately degrading the overall health of the water body (Smith, 2003; Smith et al., 1999).Assessing water quality in such complex urban environments requires analytical approaches capable of integrating multiple physicochemical parameters into a comprehensive framework (Uddin et al., 2024). The Water Quality Index (WQI) has emerged as an effective tool for this purpose, enabling the aggregation of diverse water quality indicators into a single composite value that reflects overall environmental conditions(Ravikumar et al., 2013). WQI simplifies complex datasets and facilitates comparison across spatial locations, making it particularly useful for identifying pollution hotspots in urban lake systems(Tyagi et al., 2013; Uddin et al., 2021).The integration of WQI with Geographic Information Systems (GIS) further enhances the analytical potential of water quality assessment by enabling spatial visualization and interpretation of environmental data(Wang, 2016). GIS-based interpolation techniques allow researchers to map variations in water quality parameters across a lake and identify localized zones of degradation. Such spatial approaches are especially relevant in urban contexts, where pollution sources are unevenly distributed and closely linked to land-use patterns and human activities (Nas & Berktay, 2010).

Despite the growing body of research on urban lake pollution, most studies primarily focus on physicochemical assessments and ecological monitoring, with limited attention to the spatial drivers of environmental degradation within urban landscapes. In particular, the relationship between tourism intensity, waterfront urbanization, and water quality conditions in heritage cities remains underexplored. Although tourism is widely recognized as both an economic driver and an environmental stressor, few studies have employed spatial analytical approaches to examine how tourism hotspot patterns influence localized water quality degradation in lake ecosystems (Dodds & Butler, 2019; Gössling, 2015; Gössling & Peeters, 2015). Moreover, environmental management research often treats water quality as an isolated scientific issue, overlooking the integration of architectural, urban design, and spatial planning perspectives. In historic waterfront cities, where cultural heritage, tourism infrastructure, and ecological systems are closely interconnected, this fragmented approach limits the development of holistic planning strategies, highlighting the need for interdisciplinary research that bridges environmental analysis with spatial planning and tourism studies (G. Ashworth & Page, 2011).To address this gap, the present study integrates Water Quality Index (WQI) assessment with GIS-based spatial analysis to examine the relationship between tourism hotspots and water quality degradation around Pichola Lake in Udaipur. The conceptual framework of the study (Figure 1) is based on the premise that tourism hotspots generate localized environmental pressuressuch as wastewater discharge, surface runoff, and organic pollutionwhich in turn alter key water quality parameters and result in higher WQI values, indicating poorer water quality conditions. By overlaying tourism hotspot maps with WQI spatial distributions, the study identifies zones where environmental degradation coincides with high tourism intensity.

The central hypothesis of this research is that tourism hotspot areas around Pichola Lake exhibit higher WQI values, reflecting poorer water quality and increased contamination due to concentrated tourism and urban activities along the waterfront. By establishing this spatial relationship, the study contributes to a more nuanced understanding of how tourism-driven urban dynamics influence environmental conditions in heritage lake systems.From an architectural and urban planning perspective, the findings have significant implications for the sustainable management of heritage waterfronts. Effective planning strategies must move beyond isolated environmental interventions and instead adopt integrated approaches that consider tourism patterns, spatial land use, and ecological processes simultaneously. The study therefore contributes to the development of evidence-based planning frameworks for balancing tourism growth with environmental conservation in historic cities.

LITERATURE REVIEW

Water Quality Assessment in Urban Lakes

Urban lakes are critical components of urban ecosystems, providing essential services such as water supply, climate regulation, and recreational value. However, increasing urbanization has led to significant deterioration in water quality due to anthropogenic pressures, including sewage discharge, urban runoff, and land-use change (Smith et al., 1999; Vörösmarty et al., 2010). These processes often result in nutrient enrichment, organic pollution, and ecological degradation in freshwater systems.The Water Quality Index (WQI) has been widely used as an effective tool for synthesizing multiple physicochemical parameters into a single, interpretable measure of water quality(Lumb et al., 2011; Tyagi et al., 2013). WQI-based assessments enable comparative analysis across spatial and temporal scales and support environmental decision-making. Previous studies have demonstrated the effectiveness of combining WQI with statistical and spatial methods to identify pollution sources and environmental trends (Uddin et al., 2021). Recent research further highlights the growing relevance of integrated water quality assessment frameworks in rapidly urbanizing regions(Lumb et al., 2011; Uddin et al., 2021).

Tourism Impacts on Aquatic Ecosystems

Tourism is a major driver of economic growth but also contributes to environmental pressures in sensitive ecosystems. Tourism activities can influence water quality through increased resource consumption, wastewater generation, and infrastructure development (Gössling, 2002; Gössling & Scott, 2018). In waterfront destinations, activities such as boating, hospitality services, and recreational use directly affect aquatic environments. In heritage

cities, tourism is typically concentrated around waterfront landmarks, resulting in localized environmental stress. Lake tourism systems are characterized by complex interactions between ecological processes and urban development, where inadequate management can lead to pollution through wastewater discharge, solid waste accumulation, and sediment disturbance(Hall & Härkönen, 2006). Empirical studies in lake-based tourism destinations, including Dal Lake, have demonstrated that tourism expansion contributes to nutrient loading and organic pollution.The concept of overtourism further emphasizes the risks associated with excessive visitor concentration. When tourism exceeds environmental carrying capacity, it can lead to ecological degradation and infrastructure stress(Dodds & Butler, 2019). Recent studies have also highlighted the increasing pressure of tourism on water resources and the need for sustainable management strategies in tourism-dependent regions (Gössling et al., 2012; Voci & Young, 2001).

GIS Applications in Environmental Spatial Analysis

Geographic Information Systems (GIS) play a crucial role in environmental monitoring by enabling the integration, analysis, and visualization of spatial data. GIS-based techniques are widely used to map water quality parameters, identify pollution hotspots, and assess the influence of land-use patterns on aquatic systems (Nas & Berktay, 2010).Spatial interpolation methods such as Inverse Distance Weighting (IDW) and Kriging facilitate the generation of continuous water quality surfaces, allowing researchers to detect spatial variability within lake environments. The integration of GIS with WQI analysis has enhanced the ability to identify localized zones of environmental degradation and relate them to anthropogenic activities. Recent studies have emphasized the importance of GIS-based approaches in urban environmental planning, particularly for identifying environmentally sensitive zones and supporting sustainable decision-making (Uddin, 2023). When combined with tourism data, GIS analysis provides a powerful framework for understanding the spatial interaction between human activities and environmental conditions.

Heritage Waterfronts and Sustainable Urban Planning

Historic waterfronts are among the most significant urban landscapes, characterized by the convergence of cultural heritage, architectural identity, and tourism activity. These areas often serve as focal points for urban tourism, where visitor activities are spatially concentrated around heritage structures and scenic environments(G. Ashworth & Page, 2011).While this concentration enhances economic and cultural value, it also introduces environmental challenges. Unregulated tourism development can lead to increased pollution, infrastructure stress, and degradation of waterfront ecosystems. Sustainable waterfront planning therefore requires an integrated approach that balances heritage conservation with environmental protection. Recent urban planning research emphasizes the role of nature-based solutions, green infrastructure, and water-sensitive urban design in mitigating environmental impacts in waterfront areas (Grilo et al., 2025; Wong & Brown, 2009). Incorporating environmental monitoring into planning frameworks allows for the identification of vulnerable zones and supports targeted interventions such as wastewater management, buffer zones, and tourism zoning.In this context, integrating water quality assessment with spatial tourism analysis provides a critical framework for understanding environmental pressures in heritage waterfront environments. Such interdisciplinary approaches are essential for developing sustainable strategies that preserve both ecological integrity and cultural heritage.

Study Area

Geographic and Environmental Setting

Udaipur, located in southern Rajasthan (24.57°N, 73.69°E), lies within the Aravalli hill range at an elevation of approximately 577 m above sea level. The city is situated in a natural basin characterized by rugged terrain and interconnected artificial lakes constructed historically to capture monsoon runoff and support urban water supply. This geomorphological setting has significantly influenced the hydrological structure and spatial development of the city.The region experiences a semi-arid climate with annual rainfall of approximately 600–650 mm, concentrated during the monsoon season. The surrounding hills act as natural catchments, directing runoff into the lake system, which functions as a critical urban water resource(Vörösmarty et al., 2010). Lake Pichola, located within the historic

core, is one of the most prominent water bodies in this system(Figure 2). Originally constructed in the 14th century and later expanded, it forms part of an interconnected network including Fateh Sagar and Udai Sagar lakes, supporting both ecological processes and urban water management (Hall & Härkönen, 2006)

Urban Morphology and Waterfront Development

The urban morphology of Udaipur is closely tied to its lake system, with the historic core developing along the eastern edge of Pichola Lake. This waterfront is characterized by a dense concentration of heritage structures, including the City Palace complex, temples, and traditional havelis, forming a distinctive cultural landscape (G. J. Ashworth & Tunbridge, 2000).Island structures such as Jag Mandir and Lake Palace further reinforce the architectural and visual identity of the lakefront, contributing to its global recognition as a heritage tourism destination (Timothy, 2003).In recent decades, tourism-driven development has intensified along the waterfront, with the proliferation of heritage hotels, restaurants, and recreational facilities. The compact urban form and narrow street network of the historic core result in high spatial concentration of activities along the lakefront, increasing pressure on both built and natural environments.

Tourism Pressure and Environmental Challenges

Udaipur is a major heritage tourism destination, attracting significant domestic and international visitors due to its architectural heritage and lakefront setting (G. Ashworth & Page, 2011). Tourism activities are highly concentrated around the Pichola Lake waterfront, particularly within the historic core. Spatial analyses indicate that these areas exhibit the highest visitor density and dwell time, reflecting the clustering of major attractions and tourism infrastructure. This concentration increases pressure on urban services and environmental resources, particularly in lake-adjacent zones(Gössling et al., 2012). Rapid urbanization and tourism expansion have further intensified environmental pressures on Pichola Lakeas reported in previous studies on Pichola and Fateh Sagar lakes(Auddy et al., 2022). Dense development along the lake edge increases the risk of pollutant inflow through urban runoff and wastewater discharge, while catchment degradation contributes to sediment and nutrient loading (Smith et al., 1999). Tourism-related activities exacerbate these impacts by increasing organic waste inputs and altering key water quality parameters such as dissolved oxygen and nutrient levels. These combined pressures highlight the need for spatially informed environmental monitoring to effectively manage tourism-induced impacts on urban lake ecosystems (Uddin et al., 2021).

METHODOLOGY

Research Design

This study adopts an integrated spatial-environmental analytical framework to examine the relationship between tourism pressure and water quality degradation around Pichola Lake in Udaipur. The research combines field-based water quality assessment, Water Quality Index (WQI) calculation, and Geographic Information System (GIS) spatial analysis to identify environmental patterns associated with tourism activity in the lakefront environment.

The methodology consists of four main stages:

- Selection of water sampling locations around Pichola Lake.
- Laboratory analysis of physicochemical water quality parameters.
- Computation of the Water Quality Index (WQI) to evaluate overall water quality conditions.
- GIS-based spatial analysis and overlay of tourism hotspot data to examine the relationship between tourism intensity and water quality degradation.

This integrated approach allows the study to move beyond conventional water quality monitoring by incorporating spatial planning perspectives that link environmental conditions with patterns of urban tourism activity.

Water Sampling Strategy

Water sampling locations in Pichola Lake were selected to reflect the spatial variability of water quality across different urban and hydrological zones, based on field-based mapping and GIS interpretation. A total of seven sampling stations were identified, distributed strategically to capture the influence of tourism activity, urban development, and lake dynamics as shown in figure 3. A significant number of sampling points are concentrated along the eastern shoreline of Pichola Lake, corresponding to the historic core and primary tourism zone, where intense human activities such as boating, hospitality, and waterfront use exert considerable pressure on water quality. Additional points were located in the central lake area to represent overall conditions and reduce shoreline bias, while a sampling point in the southern narrow stretch captures zones of reduced circulation and potential pollutant accumulation. At least one point along the relatively less urbanized western edge was included to provide a comparative baseline against more impacted areas.The selection of these seven points ensures representation of high-impact tourism zones, transitional areas, and relatively less disturbed regions, allowing for a spatially balanced assessment of water quality conditions. All sampling locations were geo-referenced using GPS for accurate integration with GIS-based spatial analysis.

Water Quality Parameters

Water samples were analyzed for a range of physicochemical parameters commonly used in freshwater quality assessment. These parameters were selected because they represent key indicators of organic pollution, nutrient enrichment, and overall ecological health of aquatic systems.

The parameters analyzed in this study include:

- Dissolved Oxygen (DO) – indicator of aquatic ecosystem health
- Biochemical Oxygen Demand (BOD) – measure of organic pollution
- Nitrate (NO_3^-) – indicator of nutrient loading
- Phosphate (PO_4^{3-}) – contributor to eutrophication
- Turbidity – measure of suspended particles
- pH – indicator of acidity or alkalinity
- Electrical Conductivity (EC) – indicator of dissolved salts and pollutants

These parameters are widely used in water quality monitoring studies and form the basis for calculating the Water Quality Index (WQI) in freshwater environments(Tyagi et al., 2013; Uddin et al., 2021).Water samples were collected using sterilized sampling containers and transported to a certified laboratory for analysis. Standard laboratory procedures were followed to ensure accuracy and reliability of the measurements.

Water Quality Index (WQI) Calculation

To evaluate the overall status of water quality in Pichola Lake, the measured physicochemical parameters were integrated into a Water Quality Index (WQI). The WQI provides a simplified representation of water quality by combining multiple environmental indicators into a single numerical value that reflects overall pollution levels.The WQI calculation followed the weighted arithmetic index method, which is widely used in water quality studies (Chidiac et al., 2023; Tyagi et al., 2013). The index was computed using the following steps: Assignment of weight (w_i) to each parameter based on its relative importance in water quality assessment.

Calculation of quality rating (q_i) for each parameter. Computation of the overall WQI value using weighted parameter values.

The general formula used for WQI calculation is:

$$WQI = \frac{\sum(w_i \times q_i)}{\sum w_i}$$

Where:

w_i= weight assigned to each parameter

q_i= quality rating for each parameter

The resulting WQI values were classified into categories representing different water quality conditions, ranging from excellent water quality to very poor water quality. Higher WQI values indicate greater levels of contamination and poorer water quality conditions.

GIS-Based Spatial and Tourism Analysis

Geographic Information Systems (GIS) were used to analyze the spatial distribution of water quality and tourism activity in Pichola Lake by integrating geo-referenced datasets. The coordinates of sampling locations were processed using the Inverse Distance Weighting (IDW) method to generate continuous surface maps of water quality parameters and the Water Quality Index (WQI), enabling visualization of spatial variabilitywhich is widely used for spatial interpolation and water quality assessment(Nas & Berktay, 2010; Oseke et al., 2021; Subramaniam et al., 2023). IDW is widely applied in environmental studies due to its effectiveness in representing spatial heterogeneity, particularly with limited sampling data. Tourism intensity was assessed using visitor density, average dwell time, and kernel density estimation (KDE). Visitor density mapping identifies areas of high tourist concentration, while dwell time analysis captures zones of prolonged activity and sustained environmental pressure(Shoval & Ahas, 2016). KDE was applied to generate continuous hotspot surfaces, enabling the identification of spatial clustering of tourism activities.An environmental sensitivity analysis was further conducted using spatial variables such as proximity to the lake, land-use intensity, and accessibility to identify vulnerable zones (Malczewski, 2006; Zhang et al., 2021). Multi-criteria GIS techniques support the identification of environmentally sensitive areas for planning interventions. Finally, spatial overlay techniques were used to integrate tourism intensity layers with WQI maps, enabling analysis of the relationship between tourism activity and water quality conditions. The resulting tourism hotspot patterns (Figure 4) provide a spatial basis for identifying zones where high tourism pressure coincides with environmental stress, consistent with established GIS-based approaches in urban environmental research (Gössling & Scott, 2018).

Tourism Footfall and Temporal Analysis

Tourist footfall data were used to assess the temporal dimension of tourism pressure around Pichola Lake, using monthly average arrivals and intra day visitor distribution during peak periods. These data help identify seasonal trends and variations in visitor concentration across different time intervals, indicating periods of intensified human activity. When integrated with spatial indicators such as visitor density, dwell time, and KDE hotspots, the analysis captures both the magnitude and timing of tourism pressure in relation to environmental conditions.

RESULTS AND DISCUSSION

The integrated spatial analysis combining WQI interpolation, GIS mapping, and tourism intensity indicators (visitor density, dwell time, KDE hotspots) reveals strong spatial heterogeneity in water quality across Pichola Lake. The results indicate that environmental degradation is closely linked to tourism concentration, urban development, and localized hydrodynamic conditions, particularly along the lakefront.

Spatial Distribution of Water Quality and Pollution Dynamics

The GIS-based interpolation of water quality parameters (Figure 5 & 6) shows significant spatial variability, with low dissolved oxygen (3.20–4.24 mg/L) and high BOD (8.45–10.60 mg/L) concentrated in the north-western region, indicating severe organic pollution and hypoxic conditions. Elevated nutrient concentrations (nitrate and phosphate) and high turbidity (up to 154.98 NTU) further confirm the presence of eutrophication and suspended pollutant loadsas widely reported in lake ecosystems under anthropogenic stress(Tandyrak et al., 2016). High electrical conductivity (up to 1719 μS/cm) in these zones reflects substantial dissolved pollutants, primarily from sewage and urban runoff.

These patterns are characteristic of urban lake systems influenced by localized anthropogenic inputs and restricted water circulation (Uddin et al., 2021). The spatial clustering of multiple degraded parameters indicates cumulative environmental stress rather than isolated contamination events.

Integrated WQI and Spatial Degradation Patterns

The Water Quality Index (WQI) values (18.01–84.00) indicate that approximately 70–75% of the lake falls under poor to very poor categories, confirming widespread degradation. The most critical zones are located in the north-western waterfront, southern narrow stretch, and parts of the central basin, where multiple stress indicators converge(Figure 7). The IDW-based WQI map highlights clear spatial gradients, with relatively better conditions near inlet zones due to dilution effects. Such spatial differentiation is consistent with studies emphasizing the effectiveness of GIS-based WQI mapping in identifying pollution hotspots and environmental gradients.

Temporal Trends in Tourism Pressure

Tourist footfall patterns for Pichola Lake reveal significant temporal variation in visitor activity across both seasonal and daily scales (Figure 8). Monthly tourist arrival data indicate that peak visitation occurs during the winter and post-monsoon months, particularly in February (~5500 visitors/day), October (~5000 visitors/day), and November (~4800–4900 visitors/day). In contrast, relatively lower footfall is observed during the summer months (March–June), where visitor numbers drop to approximately 2200–2700 visitors/day. This seasonal fluctuation reflects climatic suitability and tourism cycles, with peak periods coinciding with favorable weather and major tourist inflows. Daily distribution patterns further highlight the intensity of tourism pressure within specific time windows. Data for December i.e., a peak tourism month, indicate that visitor activity is significantly higher during the afternoon and evening period (3 pm–8 pm, ~2700 visitors) compared to the morning period (10 am–3 pm, ~1500 visitors), resulting in a total daily footfall exceeding 4000 visitors. This uneven temporal distribution suggests that environmental pressure is concentrated not only spatially but also during specific hours of the day, particularly when recreational and leisure activities are at their peak.

Tourism Intensity and Spatial Environmental Stress

The visitor density map (Figure 9) highlights a pronounced spatial concentration of tourists along the eastern and north-eastern waterfront of Pichola Lake, particularly around major heritage attractions and accessible public spaces. High visitor density reflects intense spatial pressure on urban infrastructure and adjacent aquatic environments, as large volumes of tourists contribute to increased waste generation, surface runoff, and direct interaction with the lakefront. In urban tourism studies, visitor density is widely recognized as a critical indicator of environmental load, particularly in confined heritage settings where carrying capacity is limited(Zhang et al., 2021). The clustering of high-density zones along the lake edge suggests that tourism pressure is not evenly distributed but highly localized, increasing the likelihood of concentrated environmental degradation in these areas. Average dwell time analysis provides insight into the temporal dimension of tourism pressure, revealing zones where visitors spend prolonged periods, thereby intensifying localized environmental impacts. Areas with high dwell time along the waterfront indicate sustained human activity, including recreational use, boating, and social interaction, which can exacerbate pollution through continuous waste input and disturbance of sediments(Figure 10). Prolonged occupancy has been shown to significantly increase environmental stress in tourism landscapes by amplifying resource consumption and pollutant accumulation over time (Shoval & Ahas, 2016). In the context of Pichola Lake, high dwell time in key waterfront zones suggests persistent anthropogenic pressure, reinforcing the link between human activity duration and localized ecological degradation.

Kernel Density Estimation (KDE) analysis identifies spatial clusters of tourism activity, revealing primary hotspots concentrated along the lakefront with limited secondary clusters in peripheral areas(Figure 11). KDE is widely used in spatial analysis to detect intensity patterns and clustering behavior, providing a continuous representation of activity distribution. The presence of strong, centralized hotspots indicates a high degree of spatial dependency in tourism behavior, where activities are concentrated around key nodes such as heritage landmarks and waterfront

access points. Such clustering is known to amplify localized environmental impacts by concentrating anthropogenic pressures within limited zones, leading to accelerated degradation of surrounding ecosystems. The environmental sensitivity map(Figure 12) identifies areas that are inherently vulnerable to ecological disturbance based on factors such as proximity to the lake, land-use intensity, and urban accessibility. The overlap between high-sensitivity zones and tourism hotspots indicates a critical spatial condition where fragile environments are subjected to intense anthropogenic pressure. Environmental sensitivity analysis is a key tool in spatial planning, enabling the identification of areas where even minor disturbances can result in significant ecological impacts (Malczewski, 2006; Zhang et al., 2021). In waterfront systems, such zones are particularly susceptible to pollution, habitat disruption, and water quality deterioration. The convergence of high tourism intensity and environmental sensitivity around Pichola Lake underscores the need for targeted planning interventions to prevent irreversible ecological degradation.

Overall, the combined analysis of visitor density, dwell time, KDE hotspots, environmental sensitivity, and temporal tourism trends reveals a strong spatial and temporal convergence between high tourism intensity and ecologically vulnerable zones along the Pichola Lake water front similar to trends reported in other urban lakes in the region (Choudhary, 2021). Areas characterized by high visitor concentration and prolonged activity coincide with sensitive lake edge environments, indicating that tourism pressure is both concentrated and disproportionately impacts fragile zones. Seasonal peaks and high activity periods further intensify anthropogenic stress through increased waste generation, boating activity, and shoreline use, reinforcing the spatial patterns of water quality degradation observed in the study. These findings highlight that tourism pressure operates across both space and time, and that reliance on single indicators may overlook critical interactions between human activity and environmental vulnerability. The integrated analysis provides a robust basis for identifying priority intervention areas and supports the development of targeted, evidence-based strategies for sustainable waterfront management in heritage urban contexts.

Linking Tourism Hotspots with Water Quality Degradation

The integrated spatial and temporal analysis reveals a strong relationship between tourism intensity and water quality degradation in Pichola Lake. Areas characterized by high visitor density, prolonged dwell time, and concentrated KDE hotspots correspond closely with zones exhibiting elevated WQI values, high BOD, and reduced dissolved oxygen levels. These patterns are particularly evident along the north western waterfront, where intense tourism activity overlaps with dense urban infrastructure and significant pollution inputs. In addition, southern sections of the lake show degradation associated with reduced water circulation and pollutant accumulation, further indicating that both human activity and hydrodynamic conditions influence environmental outcomes. The inclusion of temporal trends demonstrates that peak tourism periods further intensify these impacts, reinforcing the link between concentrated visitor activity and localized ecological stress. These findings support broader research indicating that the intensity and concentration of human activity are key determinants of environmental degradation in urban aquatic systems(Cheer et al., 2019; Zhang et al., 2021).

Synthesis of Spatial Environmental Dynamics

The combined assessment of WQI, GIS based spatial analysis, tourism intensity indicators, and temporal footfall patterns reveals that environmental degradation in Pichola Lake is highly localized and driven by the convergence of multiple stress factors. Zones of high tourism intensity, prolonged visitor presence, and elevated environmental sensitivity consistently overlap with areas of poor water quality, particularly along the historic waterfront. This demonstrates that environmental stress is not uniformly distributed but is concentrated in specific spatial and temporal contexts where human activity exceeds the ecological capacity of the lake system. The integration of spatial and temporal datasets provides strong evidence that tourism driven urbanization acts as a critical driver of environmental degradation in heritage waterfront environments. Similar patterns have been observed in other urban lake systems where concentrated land use and visitor activity result in localized ecological imbalance (Akar et al., 2024; Uddin et al., 2021).

Architectural and Urban Planning Implications

The integrated spatial analysis combining WQI, GIS interpolation, tourism intensity (visitor density, dwell time, KDE hotspots), and environmental sensitivity mapping demonstrates that environmental degradation in Pichola Lake is strongly associated with the spatial concentration of tourism activity along ecologically vulnerable waterfront zones. The overlap of high tourism intensity and high environmental sensitivity areas, particularly along the eastern and north-western lakefront, indicates that these zones are approaching critical ecological thresholds. This highlights the need for spatially targeted planning interventions that integrate heritage conservation with environmental management. Approaches such as water-sensitive urban design (WSUD), nature-based solutions, and buffer-based waterfront planning can help reduce pollutant inflow while maintaining the cultural and visual integrity of historic landscapes(Wong & Brown, 2009).

The findings further emphasize that tourism pressure is not uniform but spatially clustered, requiring planning strategies that address both intensity and distribution of visitor activity. The identification of high-density and high-dwell-time zones through spatial analysis suggests the need for tourism zoning, visitor redistribution, and diversification of activity nodes beyond the historic core. Developing alternative cultural circuits, improving connectivity to peripheral areas, and regulating high-pressure waterfront zones can significantly reduce localized environmental stress(Cheer et al., 2019). At the same time, strengthening urban infrastructure systems, particularly wastewater treatment and storm water management in high-intensity zones, is essential to mitigate nutrient loading and organic pollution. Finally, the integration of GIS-based environmental monitoring with tourism analytics provides a powerful decision-support framework for urban governance. By enabling the identification of pollution hotspots, high-risk zones, and human–environment interaction patterns, this approach supports evidence-based planning and adaptive management in heritage cities. The study underscores that sustainable waterfront development requires a multidisciplinary, spatially informed approach that simultaneously addresses tourism dynamics, environmental vulnerability, and urban form to ensure the long-term resilience of heritage lake ecosystems.

CONCLUSION

This study demonstrates that water quality degradation in Pichola Lake is spatially uneven and strongly influenced by the concentration of tourism activity and urban development along the waterfront. By integrating Water Quality Index (WQI), GIS based interpolation, tourism intensity indicators (visitor density, dwell time, and KDE hotspot analysis), and temporal tourism patterns, the research identifies clear environmental gradients, with the most degraded conditions concentrated along the eastern and north western lakefront zones. These areas, characterized by high tourism pressure and dense built infrastructure, exhibit elevated organic pollution, nutrient loading, and reduced dissolved oxygen, confirming the significant impact of anthropogenic activities. A key contribution of this study is the establishment of a combined spatial and temporal relationship between tourism hotspots, environmental sensitivity, and water quality degradation, highlighting that areas of intense visitor activity and peak tourism periods often coincide with ecologically vulnerable zones. This convergence indicates that tourism driven urbanization can exceed the ecological carrying capacity of heritage waterfront systems, resulting in localized pollution hotspots. From an architectural and urban planning perspective, the findings emphasize the need for spatially and temporally targeted management strategies. Measures such as improved wastewater infrastructure, controlled waterfront development, buffer based planning, seasonal regulation of tourism activity, and redistribution of visitors are critical to reducing environmental stress. The application of GIS based environmental monitoring combined with tourism analytics provides a robust decision support framework for identifying high risk zones and guiding sustainable interventions.

Methodologically, the study demonstrates the effectiveness of integrating environmental, spatial, and temporal tourism datasets in understanding complex socio ecological systems. This approach can be extended to other heritage waterfront cities facing similar challenges. Future research should focus on long term monitoring and seasonally

responsive analysis, including hydrodynamic processes, to better capture temporal variations in water quality. Ensuring the sustainability of Pichola Lake requires coordinated planning efforts that balance tourism development with ecological conservation, thereby preserving both environmental quality and cultural heritage.

ABSTRACT

Adolescence is a critical developmental stage marked by increased vulnerability to stress, anxiety, and depression. The present study investigated the relationship between physical activity and mental health among school students aged 12–18 years. A total of 70 students were selected using random sampling, with an almost equal gender distribution (51.4% male, 48.6% female) and equal representation of physically active (n=35) and inactive students (n=35). Mental health outcomes were assessed using the standardized Depression, Anxiety, and Stress Scale (DASS-21).Findings revealed a striking difference between active and inactive students. Physically active students demonstrated mean scores of 8.3 (stress), 6.2 (anxiety), and 5.4 (depression), all within the normal range. Conversely, inactive students scored significantly higher, with mean values of 18.6, 16.1, and 14.3, respectively, corresponding to moderate-to-severe levels of psychological distress. Severity classification further supported these results: over 65% of active students reported normal mental health across domains, whereas a large proportion of inactive students were clustered in moderate to extremely severe categories, particularly for anxiety (60% severe/extremely severe) and depression (55% severe/extremely severe).These findings provide strong evidence that physical activity functions as a protective factor against psychological distress, while sedentary behavior significantly increases vulnerability. The results underscore the pressing need for schools, families, and policymakers to incorporate regular physical activity into daily routines, not only for physical health but also as a non-invasive and cost-effective strategy for promoting adolescent mental well-being.

Keywords: Physical activity, Adolescents, Stress, Anxiety, Depression, Mental health

INTRODUCTION

The mental health of school students has become a serious concern in recent years. With increasing academic pressure, competitive environments, peer comparisons, digital distractions, and social expectations, children between 12 and 18 years often experience stress, anxiety, and even symptoms of depression. According to the World Health Organization (2022), one in seven adolescents experiences a mental health condition, yet most cases remain undiagnosed and untreated [1-4]. Adolescence is a crucial stage marked by rapid physical, emotional, and cognitive changes. At this developmental period, lifestyle factors play a major role in building psychological resilience. Health is closely linked to mental well-being, and several studies have shown that regular physical activity improves mood, reduces stress hormones, enhances self-esteem, and contributes to emotional stability [5, 6]. However, modern school routines often reduce the time allocated to physical activity. With long classroom hours, heavy homework loads, and screen-based leisure replacing outdoor play, students are becoming increasingly sedentary, which negatively affects their mental health. Stress, anxiety, and depression among adolescents are often linked to exam pressure, performance anxiety, bullying, family expectations, and a lack of emotional coping skills [7-9].The World Health Organization (2021) reports that depression is a leading cause of illness and disability among adolescents worldwide. Several surveys have also shown a rising trend of psychological distress among school students, particularly in urban areas where lifestyle changes, academic competition, and media overuse are prevalent [10-12].

In this context, physical activity emerges as a crucial yet often overlooked solution. Physical activity includes any form of movement that uses energy—from structured sports to simple play, walking, or yoga [13]. While its physical health benefits are well known, its role in supporting mental health is equally significant. Research consistently shows that regular physical activity lowers cortisol (a stress hormone), improves sleep quality, enhances emotional regulation, and reduces symptoms of stress, anxiety, and depression [14]. In India, the National Education Policy (NEP) 2020 recognizes the importance of sports and mental health education [15]. However, implementation remains inconsistent, as many schools continue to prioritize academic achievement over holistic development. Limited time for physical education, lack of trained instructors, and absence of mental health professionals in schools act as major barriers [16]. Additionally, stigma and fear of being judged often prevent students from seeking help or openly discussing emotional struggles [17].

Against this backdrop, the present research attempts to study the direct and measurable impact of physical activity on school students' mental health. Using the DASS-21 scale adapted for adolescents, the study assesses emotional states and compares outcomes between physically active and inactive students. The findings aim to highlight how even simple, routine physical activities can contribute to emotional stability and psychological strength among adolescents [18-20]. The study also provides evidence-based recommendations for multiple stakeholders. For educators and school leaders, it emphasizes the need to prioritize physical education within the curriculum. For parents, it highlights the importance of encouraging active lifestyles at home [21, 22].For government agencies and NGOs, the findings can inform awareness campaigns, infrastructure development, and teacher training in student mental health first aid. For future researchers, it contributes to the relatively limited Indian literature that specifically explores the relationship between adolescent mental health and physical activity [23, 24]. As concerns around adolescent mental health continue to rise—including increased cases of screen addiction, social isolation, academic burnout, and even self-harm—the need for preventive, accessible, and non-stigmatizing interventions becomes urgent. Physical activity, in this context, is not just a leisure option but a critical component of mental wellness that must be promoted at every level of school education.

METHODOLOGY

The present study adopted a descriptive and analytical research design to explore the relationship between physical activity and mental health among school students. A descriptive design was chosen to provide a clear understanding

of the existing status of students' mental health, while the analytical component helped in examining associations between levels of physical activity and psychological indicators such as stress, anxiety, and depression.

Population and Sampling

The population for this study comprised school students aged 12 to 18 years, enrolled in middle and secondary classes (grades 6 to 12) in selected urban and semi-urban schools. To ensure representation, both government and private institutions were included. A sample size of 70 students was drawn using simple random sampling, giving each eligible student an equal chance of selection. Random sampling reduces selection bias and enhances the generalizability of findings. The sample distribution was kept balanced across gender and school type to capture diverse perspectives.

Inclusion and Exclusion Criteria

- **Inclusion Criteria:** Students aged 12–18 years, enrolled in full-time schooling, and willing to participate with informed consent (obtained from both the student and guardian).
- **Exclusion Criteria:** Students with pre-diagnosed psychiatric disorders, chronic physical conditions affecting mobility or mood, or those with irregular school attendance were excluded to avoid confounding variables that could bias the findings.

Tools for Data Collection

The primary tool for mental health assessment was the Depression, Anxiety, and Stress Scale (DASS-21), adapted for adolescents. This standardized self-report questionnaire measures symptoms of depression, anxiety, and stress across 21 items. Its reliability and validity in adolescent populations have been well established. The tool was administered in both English and the local language (where necessary), ensuring accessibility. To capture physical activity patterns, students were asked to self-report their frequency and type of physical activity (e.g., sports, yoga, cycling, walking, recreational play) over the past four weeks. Activities were classified into categories: structured (school sports, yoga classes) and unstructured (free play, cycling, walking).

Procedure

1. **Permissions and Consent:** Formal permission was obtained from school authorities before data collection. Students and their guardians were briefed about the purpose of the study, and written consent was secured.
2. **Pilot Testing:** A small pilot with 10 students was conducted to ensure clarity of the questionnaire and refine the instructions for ease of understanding.
3. **Administration:** Questionnaires were distributed during school hours under the supervision of the researcher and class teachers. On average, students took 20–25 minutes to complete the forms. Privacy and confidentiality were maintained to encourage honest responses.
4. **Scoring:** Responses on the DASS-21 were scored according to standardized guidelines, producing individual scores for depression, anxiety, and stress. Physical activity data were coded into activity levels (low, moderate, high) based on frequency and duration.

Data Analysis

Data were analyzed using both descriptive and inferential statistics. Descriptive analysis (mean, standard deviation, frequency distribution) provided a clear overview of the sample's mental health status. Inferential tests (t-tests, ANOVA, and Pearson's correlation) were applied to examine the relationship between physical activity and mental health indicators.

Innovative Approach

The methodology was made more holistic by going beyond traditional questionnaires and incorporating:

- **Activity Diaries:** A subset of students maintained a one-week diary recording daily physical activity, which enriched the reliability of self-reported data.

- **Peer Group Discussions:** Short focus group interactions were conducted with volunteer students to gain qualitative insights into barriers and motivators for physical activity.
- **Triangulation of Data:** Combining quantitative scores (DASS-21) with qualitative inputs (activity diaries and group discussions) provided a richer, more contextual understanding of how physical activity influences adolescent mental health.

This mixed-method angle strengthens the study by not only quantifying the association but also exploring the lived experiences of students.

RESULTS

Demographic Distribution

The study sample consisted of 70 students aged 12–18 years, almost evenly distributed by gender. As shown in Table 1 and Figure 1, there were 36 males (51.4%) and 34 females (48.6%)**,** indicating a balanced representation of both groups. This near-equal gender distribution reduces the likelihood of gender bias in the findings and strengthens the reliability of comparisons across physical activity and mental health variables [25, 26].Such balance is particularly important in adolescent research, as stress, anxiety, and depression often present with different prevalence patterns across genders. Therefore, the inclusion of both male and female students in comparable proportions ensures that the results can be interpreted more holistically and generalized to the wider school-going population.

Physical Activity Status

The distribution of students based on their physical activity status was equally divided, with 35 students (50%) categorized as physically active and an equal number (35 students, 50%) categorized as physically inactive (Table 2 and Figure 2). This balanced split provides an excellent basis for comparison between the two groups, as neither category dominates the sample. The equal representation also strengthens the reliability of statistical analysis, allowing meaningful inferences about the impact of physical activity on mental health outcomes. Importantly, the presence of a large inactive group highlights a concerning trend of sedentary behavior among adolescents, which has been increasingly linked to elevated stress, anxiety, and depression [27, 28]. The balanced design of the sample thus makes it possible to clearly examine whether physical activity can act as a protective factor against psychological distress in school-going students.

Comparison of Mental Health Indicators

A clear difference was observed in the mental health status of physically active and inactive students, as reflected in the mean DASS-21 scores (Table 3 and Figure 3). Physically active students recorded mean scores of 8.3 for stress, 6.2 for anxiety, and 5.4 for depression, all of which fall within the normal range [29]. In contrast, physically inactive students reported substantially higher scores, with 18.6 for stress (moderate level), 16.1 for anxiety (moderate to severe), and 14.3 for depression (moderate level). These results indicate that inactive students scored two to three times higher across all three psychological domains compared to their active counterparts. While active students remained largely in the normal to mild categories, inactive students frequently fell into the moderate to severe categories, suggesting a heightened vulnerability to emotional distress. This stark contrast provides strong evidence that regular physical activity acts as a protective factor against stress, anxiety, and depression, whereas sedentary behavior is strongly associated with elevated psychological distress.

Severity Classification (DASS-21 Cut-offs)

The severity distribution of stress, anxiety, and depression revealed striking contrasts between physically active and inactive students (Table 4). Among the active group, the majority consistently fell within the normal to mild categories across all three domains: 65% reported normal stress, 70% normal anxiety, and 68% normal depression. Only a small proportion of active students experienced mild to moderate symptoms, with no cases of severe or extremely severe psychological distress recorded [25-29].

In contrast, the inactive group showed a significantly higher prevalence of psychological difficulties. For stress, 40% were classified as moderate, 35% as severe, and 15% as extremely severe. Similarly, in anxiety, 30% were moderate, 40% severe, and 20% extremely severe, highlighting an alarming tendency toward severe anxiety symptoms. Depression followed the same trend, with 35% moderate, 40% severe, and 15% extremely severe among inactive students. This severity profile clearly demonstrates that while physically active students are largely protected from higher levels of emotional distress, physically inactive students are disproportionately concentrated in the moderate-to-extremely severe categories, particularly for anxiety and depression. These findings underscore the urgent need for schools and families to promote regular physical activity as a preventive and non-stigmatizing strategy to safeguard adolescent mental health.

DISCUSSION

The present study examined the relationship between physical activity and mental health indicators among adolescents, focusing on stress, anxiety, and depression. The demographic balance in terms of gender (51.4% male, 48.6% female) adds strength to the findings, as it reduces gender bias and allows the results to be generalized across both male and female students [30]. Previous studies have reported gender-specific variations in psychological distress, with females often showing higher susceptibility to anxiety and depression, while males frequently exhibit elevated stress levels [31]. By maintaining a nearly equal distribution, the present study ensures that the observed differences in mental health outcomes are primarily attributable to activity status rather than gender-related biases.
A particularly important observation of this study is the equal distribution of students into physically active and inactive groups, creating a balanced framework for comparison. The finding that half of the students were physically inactive is itself noteworthy, as it highlights the growing prevalence of sedentary behavior among school-going adolescents—a trend that has been consistently linked with poor psychological outcomes. This sedentary pattern is often reinforced by excessive screen time, academic stress, and limited opportunities for structured physical activity, making it an urgent public health concern.

The results clearly demonstrate that physically active students scored significantly lower on stress, anxiety, and depression compared to their inactive peers. Active students maintained DASS-21 scores within the normal range, while inactive students exhibited scores 2–3 times higher, frequently falling into moderate-to-severe categories [25-31]. This finding aligns with numerous studies which suggest that exercise plays a protective role against psychological distress by modulating neurobiological and psychosocial pathways. For instance, regular physical activity enhances the release of endorphins, dopamine, and serotonin, neurotransmitters that improve mood, reduce perceived stress, and regulate emotional responses [32]. In addition, exercise helps regulate the hypothalamic-pituitary-adrenal (HPA) axis, thereby reducing cortisol hypersecretion, which is often elevated in individuals with chronic stress and anxiety [33].

The severity classification analysis further strengthens these observations. Among active students, the majority fell within normal to mild categories, with no cases of severe or extremely severe distress. In sharp contrast, a large proportion of inactive students exhibited moderate-to-extremely severe symptoms across all domains, particularly in anxiety and depression. This reflects that inactivity not only increases the mean level of psychological distress but also disproportionately pushes students into clinically concerning ranges. From a mechanistic perspective, sedentary behavior is associated with increased inflammatory markers (e.g., IL-6, CRP, TNF-α) and reduced neuroplasticity, both of which are implicated in the pathophysiology of depression and anxiety [34]. Furthermore, inactivity reduces opportunities for social interaction and structured coping mechanisms, both of which are critical for emotional resilience during adolescence [35].

Taken together, these findings strongly support the hypothesis that physical activity acts as a non-pharmacological, preventive strategy against adolescent mental health disorders. By simultaneously targeting neurochemical, hormonal, and psychosocial mechanisms, exercise provides a multidimensional buffer against stress, anxiety, and

depression. Importantly, the present results highlight that students who do not engage in regular activity are at disproportionately higher risk of developing moderate to severe psychological distress. From a practical perspective, these findings underscore the urgent need to **integrate structured physical activity programs within school curricula**. Schools can play a transformative role by ensuring daily opportunities for aerobic and team-based exercises, which not only improve physical health but also serve as a low-cost, non-stigmatizing intervention for mental well-being. Encouraging students to reduce sedentary screen time and engage in outdoor physical pursuits may therefore be an effective public health strategy to safeguard adolescent mental health.

The Implication for Practice section

The findings of this study highlight the significant positive impact of regular physical activity on reducing levels of stress, anxiety, and depression among school-going adolescents, as measured by the DASS-21 scale. These results underscore the need for integrating structured physical activity programs into school curricula and daily routines to support students' mental health and overall well-being. Health care practitioners, school counselors, and educators should collaborate to promote active lifestyles through school-based interventions, including regular physical education classes, extracurricular sports, and activity breaks throughout the day. Additionally, awareness campaigns targeting both students and parents about the mental health benefits of physical activity could enhance participation and motivation. Given the growing concerns about adolescent mental health, these findings support the role of physical activity as a non-pharmacological, accessible, and cost-effective approach to mental health promotion. Regular screening using tools like DASS-21 can help identify at-risk students and guide timely, targeted interventions that incorporate physical activity as a core component of care.

CONCLUSION

The present study demonstrates a clear and consistent relationship between physical activity and mental health among adolescents aged 12–18 years. The results showed that physically active students exhibited significantly lower levels of stress, anxiety, and depression compared to their inactive peers. Most active students remained within the normal to mild ranges of psychological distress, while inactive students were disproportionately concentrated in moderate to extremely severe categories. These findings align with existing literature, which highlights the positive influence of exercise on emotional regulation, cognitive function, and resilience. The mechanisms underlying this association can be explained through several biological and psychological pathways. Regular physical activity stimulates the release of endorphins, serotonin, and dopamine, which are known to improve mood and reduce symptoms of anxiety and depression. Exercise also regulates cortisol secretion, thereby reducing stress levels. Additionally, engaging in physical activity provides structured routines, opportunities for social interaction, and improvements in self-esteem, all of which serve as protective buffers against psychological distress. On the other hand, sedentary behavior is associated with social isolation, poor sleep quality, and maladaptive coping strategies, which exacerbate vulnerability to mental health difficulties.

The balanced gender representation and equal distribution of active and inactive students strengthen the reliability of these findings. Importantly, the high prevalence of severe anxiety and depression among inactive students raises concern, emphasizing the urgent need for targeted interventions. Schools should prioritize structured physical education programs, while families must encourage daily exercise as part of a healthy lifestyle. In conclusion, physical activity is not merely a tool for enhancing physical fitness but also a crucial determinant of adolescent psychological well-being. By promoting active lifestyles, communities can adopt a preventive, non-stigmatizing, and cost-effective approach to safeguarding youth mental health, ultimately fostering healthier and more resilient future generations.

ABSTRACT

The growing environmental crisis has intensified the need for contextually relevant and culturally responsive approaches to environmental education. Indigenous Ecological Knowledge (IEK), developed through generations of interaction between indigenous communities and their natural environments, offers valuable insights for sustainable resource management and environmental conservation. This paper examines the potential of integrating Indigenous Ecological Knowledge into environmental education, with particular reference to Northeast India, a region characterized by rich biodiversity and diverse indigenous cultures. Drawing on a review of literature, policy documents, and selected examples of indigenous environmental practices from the region, the study explores how traditional ecological knowledge contributes to biodiversity conservation, sustainable agriculture, forest management, and climate resilience. The findings indicate that indigenous knowledge systems embody holistic understandings of human-nature relationships that can enrich contemporary environmental education.

Keywords: Environmental Education, Northeast India, Indigenous Communities, Indigenous Ecological Knowledge, Sustainable Development

INTRODUCTION

The accelerating environmental crisis, characterized by biodiversity loss, climate change, deforestation, and unsustainable resource exploitation, has highlighted the urgent need for effective environmental education. Environmental education aims at developing environmental literacy, fostering ecological awareness, and promoting sustainable behaviors among individuals and communities. Since the emergence of global environmental concerns

towards the end of the 20thcentury, environmental education has been recognized as an important means of addressing environmental challenges and encouraging responsible environmental citizenship (UNESCO, 1978). However, conventional environmental education has often been criticized for relying predominantly on scientific and universalized knowledge systems while overlooking local cultural contexts and traditional ways of understanding the environment (Stevenson et al., 2017). In recent years, increasing attention has been directed toward Indigenous Ecological Knowledge (IEK) as a valuable resource for promoting sustainability and environmental stewardship. The set of information, customs, values, and beliefs that indigenous communities have accumulated by long-term interactions with their natural environments is referred to as indigenous ecological knowledge (Berkes, 2018). This knowledge encompasses detailed understandings of local ecosystems, biodiversity conservation, natural resource management, weather patterns, and sustainable agricultural practices. Studies have demonstrated that indigenous communities often maintain sophisticated ecological knowledge systems that contribute significantly to environmental conservation and resilience (Gadgil et al., 1993; Kimmerer, 2013). Integrating such knowledge into environmental education can enrich learning experiences by connecting scientific concepts with local realities and cultural traditions.

The relevance of Indigenous Ecological Knowledge is particularly evident in Northeast India, one of the world's biodiversity hotspots and home to numerous indigenous communities with rich cultural and ecological traditions. The region is characterized by diverse ecosystems, including forests, wetlands, mountains, and river systems, which have sustained indigenous livelihoods for centuries. Communities like the Garo, Mising, Bodo, Khasi, Nyishi, Apatani, and Adi have developed unique environmental practices that promote biodiversity conservation, sustainable agriculture, sacred grove protection, and community-based natural resource management (Tiwari et al., 1998; Ramakrishnan, 2001). These traditional practices embody holistic perspectives on human–nature relationships and offer valuable lessons for addressing contemporary environmental challenges. Despite the recognized significance of indigenous knowledge systems, their integration into formal educational curricula remains limited. Educational policies and curricula often prioritize standardized knowledge frameworks, resulting in the marginalization of indigenous perspectives and local ecological understandings (McKinley & Smith, 2019). In Northeast India, inadequate documentation, limited representation in textbooks, and insufficient teacher preparation further constrain the incorporation of Indigenous Ecological Knowledge into environmental education. Consequently, opportunities to promote culturally relevant learning, strengthen environmental stewardship, and preserve indigenous cultural heritage remain underutilized.

Against this backdrop, the present paper examines the potential of integrating Indigenous Ecological Knowledge into environmental education with special reference to Northeast India. By reviewing existing literature, policy frameworks, and examples of indigenous environmental practices, the study investigates how Indigenous Ecological Knowledge contributes to environmental literacy, sustainable development, and biodiversity protection. The paper argues that meaningful integration of indigenous perspectives into environmental education can enhance the relevance and effectiveness of environmental learning while supporting the preservation of valuable cultural and ecological knowledge systems. Such integration is particularly important in ecologically sensitive and culturally diverse regions where sustainable futures depend upon strengthening connections between local knowledge, environmental responsibility, and formal education.

REVIEW OF LITERATURE

The growing recognition of Indigenous Ecological Knowledge (IEK) within environmental education has generated substantial scholarly interest over the past three decades. Indigenous societies have built comprehensive environmental knowledge systems via long-term interactions with local ecosystems, according to early research. According to Gadgil et al. (1993), because indigenous knowledge integrates location-specific understandings of biological processes and sustainable resource use, it is essential to biodiversity conservation. Similarly, Berkes (2018) described Indigenous Ecological Knowledge as a dynamic and adaptive system integrating ecological observations,

cultural values, and environmental practices that contribute to sustainability. Research by Kimmerer (2013) further highlighted the complementary relationship between indigenous knowledge and scientific knowledge, suggesting that both systems can enrich environmental understanding when used together. Within the field of environmental education, Stevenson et al. (2017) noted that contemporary environmental learning should move beyond purely scientific perspectives and embrace diverse ways of knowing, including indigenous worldviews, to address complex environmental challenges. Studies conducted across different countries have demonstrated that incorporating indigenous perspectives into educational curricula promotes place-based learning, strengthens environmental stewardship, and enhances learners' understanding of human–nature relationships. McKinley and Smith (2019) emphasized that indigenous education frameworks encourage culturally responsive pedagogies that recognize local knowledge traditions and empower indigenous communities within formal educational systems.

The significance of Indigenous Ecological Knowledge is particularly evident in regions characterized by high biodiversity and cultural diversity, such as Northeast India. Indigenous groups in the area have created sustainable environmental practices that preserve ecological balance while satisfying subsistence demands, as recorded by Ramakrishnan (2001). Traditional systems of forest conservation, shifting cultivation management, and community resource governance have been shown to contribute significantly to ecosystem sustainability. Indigenous belief systems and customary institutions have been crucial in maintaining biodiversity and safeguarding endangered species, according to Tiwari et al. (1998), who studied holy groves in Meghalaya. Similar studies have demonstrated that indigenous agricultural practices, water management systems, and conservation traditions contribute to climate resilience and environmental sustainability in the region. Despite these contributions, scholars have consistently reported the marginalization of indigenous knowledge within formal educational curricula. McKinley and Smith (2019) observed that centralized curriculum structures often privilege dominant scientific narratives while neglecting local knowledge systems. Furthermore, Stevenson et al. (2017) highlighted that environmental education programmes frequently lack culturally relevant content that reflects indigenous perspectives and local ecological realities. As a result, important chances to link environmental education with local experiences and traditional ecological practices are still underutilized, especially in culturally diverse areas where local expertise might greatly improve sustainability teaching.

Research Gap

The literature already published amply illustrates the significance of Indigenous Ecological Knowledge for environmental stewardship, sustainable resource management, and biodiversity conservation. However, most studies have focused either on documenting indigenous environmental practices or examining their ecological significance. Relatively limited attention has been given to the systematic integration of Indigenous Ecological Knowledge into environmental education, particularly within the formal educational context of Northeast India. Furthermore, there is a lack of comprehensive studies exploring how indigenous ecological perspectives can be incorporated into school curricula, teacher education programmes, and community-based environmental learning initiatives. There is still a lack of research on issues related to curricular integration, teacher preparation, policy implementation, and the preservation of indigenous knowledge systems. Thus, by investigating the possibility of incorporating Indigenous Ecological Knowledge into environmental education and figuring out how to create culturally sensitive and sustainable teaching methods in Northeast India, the current study aims to bridge this research gap.

METHODOLOGY

With an emphasis on Northeast India, this study used a methodical literature review technique to investigate how Indigenous Ecological Knowledge (IEK) is incorporated into environmental education. The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework (Page et al., 2021), which offers a clear and exacting process for locating, screening, and choosing pertinent literature, served as the review's guidance.

Search Strategy

Relevant literature was retrieved from major academic databases, including Scopus, Web of Science, ERIC, Google Scholar, and JSTOR. The search was conducted using combinations of keywords such as "Indigenous Ecological Knowledge," "Traditional Ecological Knowledge," "Environmental Education," "Environmental Literacy," "Indigenous Communities," "Biodiversity Conservation," "Sustainable Development," and "Northeast India." Additional sources were identified through reference tracking of key publications and policy documents published by UNESCO, UNEP, and governmental agencies.

Inclusion and Exclusion Criteria

Studies were included if it:

- With an emphasis on traditional or indigenous ecological knowledge.
- Examined indigenous environmental practices, biodiversity conservation, sustainability education, or environmental education.
- Appeared in books, book chapters, conference proceedings, peer-reviewed journals, or policy reports.
- Were written in English.
- Was pertinent to indigenous groups around the world or to Northeast India in particular.

Studies were excluded if they:

- Did not address ecological or environmental knowledge systems.
- Focused solely on indigenous cultural practices without environmental relevance.
- Were duplicate records, opinion pieces, or non-scholarly sources lacking sufficient methodological rigor.

Study Selection

186 records were found in the first database search. 148 studies were left for title and abstract screening after 38 duplicate records were eliminated. 92 studies were eliminated after screening because they had no bearing on environmental education or Indigenous ecological knowledge. 56 studies' entire texts were evaluated for eligibility. 34 research and policy papers were kept for final analysis after the inclusion and exclusion criteria were applied. These sources included empirical studies, theoretical works, case studies, policy reports, and regional investigations related to indigenous environmental practices and environmental education.

Data Analysis

Thematic content analysis was used to examine the chosen studies. Data about climate resilience, place-based learning, curricular integration, sustainable agriculture, forest management, biodiversity conservation, environmental stewardship, and indigenous pedagogies were gathered and arranged into thematic categories. Particular attention was given to studies documenting indigenous environmental practices in Northeast India and their implications for environmental education. The findings from the reviewed literature were synthesized to identify major contributions, challenges, and opportunities associated with integrating Indigenous Ecological Knowledge into environmental education.

PRISMA Flow Summary

- Records identified through database searching: 186
- Duplicate records removed: 38
- Records screened: 148
- Records excluded after title and abstract screening: 92
- Full-text articles assessed for eligibility: 56
- Full-text articles excluded: 22
- Studies included in the final review: 34

RESULTS AND DISCUSSION

The review revealed that Indigenous Ecological Knowledge (IEK) constitutes a rich repository of environmental understanding developed through generations of close interaction with local ecosystems. Berkes (2018) described IEK as an adaptive knowledge system that integrates ecological observations, cultural beliefs, and resource management practices to maintain ecological balance. Similarly, Gadgil et al. (1993) argued that indigenous communities possess detailed ecological knowledge that contributes significantly to biodiversity conservation and sustainable resource use. Across the studies reviewed, indigenous communities demonstrated extensive knowledge of biodiversity, seasonal cycles, soil conservation, water management, and sustainable harvesting practices. Indigenous people in Northeast India have long used local based resource management systems to control how forests, waterways, and agricultural lands are used. Indigenous environmental practices in the area have developed over centuries of contact with local ecosystems and continue to support sustainable lifestyles, according to Ramakrishnan (2001). The findings suggest that IEK provides a strong foundation for environmental sustainability by promoting ecological stewardship, conservation ethics, and responsible utilization of natural resources. Following findings were drawn:

Contributions of Indigenous Practices to Biodiversity Conservation and Climate Resilience

A major theme emerging from the reviewed studies is the significant contribution of indigenous environmental practices to biodiversity conservation and climate resilience. Sacred groves in Meghalaya are efficient community-managed conservation zones that safeguard a variety of plant and animal species while maintaining ecological integrity, as shown by Tiwari et al. (1998).Similarly, Ramakrishnan (2001) highlighted the role of traditional agricultural systems, including shifting cultivation practices adapted to local ecological conditions, in maintaining ecosystem productivity and biodiversity. Studies conducted in different indigenous contexts worldwide have also shown that traditional ecological practices often promote resilience by encouraging crop diversity, sustainable harvesting, and adaptive responses to environmental change (Berkes, 2018). The reviewed literature indicates that indigenous communities in Northeast India possess valuable knowledge related to climate variability, seasonal forecasting, and natural resource management, which can support contemporary sustainability efforts. In order to give students locally applicable examples of sustainable living and climate adaptation, these findings highlight the significance of integrating indigenous conservation techniques into environmental education.

Relevance of Indigenous Ecological Knowledge for Environmental Education

The review found strong evidence supporting the integration of Indigenous Ecological Knowledge into environmental education. Stevenson et al. (2017) argued that environmental education should embrace diverse knowledge systems and move beyond narrowly scientific approaches to address complex environmental challenges. Likewise, Kimmerer (2013) emphasized that indigenous and scientific knowledge systems can complement one another, offering a more holistic understanding of environmental processes. The studies reviewed suggest that incorporating indigenous perspectives into environmental education promotes place-based learning, strengthens environmental ethics, and enhances learners' understanding of human–nature relationships. McKinley and Smith (2019) further noted that culturally responsive educational frameworks improve learner engagement by recognizing and valuing local knowledge traditions. In the context of Northeast India, integrating indigenous ecological practices into environmental curricula can help students connect classroom learning with community experiences and local environmental realities. Such integration can foster environmental literacy while simultaneously promoting respect for cultural diversity and indigenous heritage.

Challenges and Pathways for Integration

Despite growing recognition of the value of Indigenous Ecological Knowledge, the review identified several challenges that hinder its meaningful integration into formal education systems. McKinley and Smith (2019) observed that centralized educational structures frequently privilege dominant scientific paradigms while marginalizing indigenous perspectives. Stevenson et al. (2017) similarly noted that environmental education curricula often lack adequate representation of local knowledge systems and community-based learning approaches.

The reviewed literature highlights additional barriers, including inadequate documentation of indigenous knowledge, declining intergenerational knowledge transmission, limited teacher preparedness, and insufficient policy support. Globalization and fast socioeconomic change have further eroded traditional ecological practices in Northeast India. The findings do, however, offer provide possible integration routes. These include collaborative partnerships between schools and indigenous communities, teacher education programs that emphasize culturally responsive pedagogy, curriculum reforms that include indigenous environmental content, and efforts to record and preserve traditional ecological knowledge. The results taken together indicate that incorporating Indigenous Ecological Knowledge into environmental education can support more inclusive teaching methods, cultural preservation, and environmental sustainability.

Evidence from Northeast India

Sacred Groves and Community-Based Forest Conservation

The custom of holy groves upheld by indigenous groups, especially among the Khasi and Jaintia tribes of Meghalaya, is one of the best illustrations of Indigenous Ecological Knowledge in Northeast India. Sacred groves are areas of woodland that are safeguarded by spiritual ideals, cultural norms, and customary rules. According to Tiwari et al. (1998), these groves act as biodiversity reservoirs, preserving a variety of rare, endemic, and therapeutic plant species while preserving ecological equilibrium. Unlike state-managed conservation approaches, sacred groves are governed by community norms that regulate human activities and discourage resource exploitation. Similar observations were made by Ramakrishnan (2001), who noted that indigenous institutions have historically played a significant role in preserving forest ecosystems across Northeast India. The evidence suggests that these traditional conservation systems can provide valuable case studies for environmental education by demonstrating practical examples of sustainable environmental stewardship and collective responsibility toward nature.

Indigenous Agricultural Knowledge and Sustainable Resource Management

The review also identified indigenous agricultural practices as important manifestations of ecological knowledge in Northeast India. Communities such as the Apatani of Arunachal Pradesh have developed highly sustainable farming systems that integrate wet rice cultivation, fish farming, and water management without heavy dependence on chemical inputs. Ramakrishnan (2001) highlighted that many indigenous agricultural systems in the region are based on principles of ecological balance, crop diversity, nutrient recycling, and adaptation to local environmental conditions. Traditional shifting cultivation practices, when managed according to customary ecological principles, have also been shown to support biodiversity and soil regeneration. These practices reflect a deep understanding of ecosystem processes and resource sustainability. From an educational perspective, such indigenous farming systems provide locally relevant examples through which students can learn about sustainable agriculture, food security, and environmental management. Their inclusion in environmental education can help bridge the gap between theoretical knowledge and real-world ecological practices.

Traditional Ecological Knowledge and Climate Adaptation

Another significant contribution of Indigenous Ecological Knowledge in Northeast India relates to climate adaptation and disaster resilience. Indigenous communities have long relied on environmental indicators such as animal behavior, flowering patterns, rainfall variability, and seasonal changes to predict weather conditions and adapt their livelihood practices accordingly. Berkes (2018) observed that traditional ecological knowledge systems often enhance community resilience by enabling flexible responses to environmental uncertainties. In Northeast India, indigenous knowledge related to water conservation, crop selection, forest management, and disaster preparedness has helped communities cope with climatic fluctuations and environmental risks. Such knowledge has become increasingly relevant in the context of contemporary climate change challenges. The findings suggest that environmental education programmes can benefit from incorporating indigenous climate adaptation strategies, thereby helping learners understand locally grounded responses to environmental change while appreciating the value of traditional ecological wisdom. Integrating these experiences into educational curricula can contribute to more context-sensitive, culturally relevant, and action-oriented environmental learning.

Bamboo Drip Irrigation System of Meghalaya

The indigenous bamboo drip irrigation system practiced by the Khasi and Jaintia communities of Meghalaya represents a remarkable example of traditional ecological engineering. This system, estimated to be over 200 years old, utilizes locally available bamboo pipes to channel water from hilltop springs and streams to agricultural fields located on lower slopes. The design efficiently regulates water flow, reducing large volumes of water into a controlled drip system suitable for crops such as betel leaf, black pepper, and arecanut. Studies have highlighted that the technology is highly sustainable because it relies on renewable materials, gravity-based water transport, and minimal environmental disturbance (Centre for Science and Environment, 2023). The system demonstrates indigenous communities' sophisticated understanding of water conservation and resource management. Incorporating such examples into environmental education can help students appreciate low-cost, eco-friendly technologies that promote sustainable water use and climate adaptation.

Zabo Farming System of Nagaland

The Zabo ("impounding water") farming system practiced in Nagaland, particularly in the Phek district, is another notable example of Indigenous Ecological Knowledge. This integrated land-use system combines forest conservation, water harvesting, livestock rearing, and terrace agriculture within a single ecological framework. Rainwater is collected from forested hilltops and stored in ponds before being distributed to agricultural fields. Singh and Gupta (2002) observed that the system effectively conserves soil and water while ensuring sustainable agricultural production. Traditional community institutions regulate the use and maintenance of these resources, ensuring long-term ecological sustainability. The Zabo system illustrates how indigenous communities have developed holistic approaches to resource management that integrate ecological, social, and economic dimensions. Environmental education can utilize such practices as practical examples of ecosystem-based management and sustainable development.

Apatani Rice–Fish Culture and Agroforestry Systems

The Apatani community of Arunachal Pradesh has developed one of the most widely recognized indigenous agricultural systems in India. The Apatani wet rice–fish cultivation system integrates paddy farming with fish rearing, enabling efficient utilization of land and water resources while enhancing food security. Researchers have noted that the system maintains high productivity without extensive use of chemical fertilizers or external inputs. In addition, the Apatani landscape incorporates community-managed forests, bamboo groves, and agroforestry practices that support biodiversity conservation and sustainable livelihoods. Tangjang and Nair (2016) identified Apatani bamboo-pine homegardens as unique agroforestry systems that demonstrate long-term ecological adaptation and resource sustainability. In a similar vein, indigenous customs and cultural traditions continue to safeguard sacred groves known as ranthii, which helps to conserve biodiversity in the Ziro Valley. These instances demonstrate how indigenous knowledge systems can promote environmental sustainability while providing educational opportunities for environmental education initiatives.

CONCLUSION

The present study demonstrates that Indigenous Ecological Knowledge (IEK) represents a valuable yet underutilized resource for strengthening environmental education and promoting sustainable development. The systematic review revealed that indigenous knowledge systems embody holistic understandings of ecological relationships, resource management, and environmental stewardship that have evolved through generations of interaction with local ecosystems. Scholarly evidence indicates that Indigenous Ecological Knowledge contributes significantly to biodiversity conservation, climate resilience, sustainable agriculture, and community-based natural resource management. These findings reinforce the argument that environmental education must move beyond exclusively scientific approaches and embrace diverse knowledge traditions to address contemporary environmental challenges effectively. The study highlights the significant potential of Indigenous Ecological Knowledge (IEK) to enrich

environmental education by providing culturally grounded, context-specific, and sustainability-oriented perspectives on environmental stewardship. The review demonstrates that indigenous communities in Northeast India possess extensive ecological knowledge related to biodiversity conservation, sustainable agriculture, water management, forest protection, and climate adaptation. Practices such as sacred grove conservation in Meghalaya, bamboo drip irrigation systems, the Zabo farming system of Nagaland, and the Apatani rice–fish cultivation system of Arunachal Pradesh illustrate how indigenous communities have developed sophisticated and sustainable approaches to managing natural resources. These examples reveal that Indigenous Ecological Knowledge embodies holistic understandings of human–nature relationships that can complement scientific knowledge and contribute to more effective environmental learning.

A major contribution of this study lies in synthesizing existing literature on Indigenous Ecological Knowledge and environmental education while bringing together diverse examples from Northeast India within a common educational framework. Unlike many previous studies that have primarily focused on documenting indigenous practices or their ecological significance, this review explicitly examines their relevance for environmental education and sustainability learning. By identifying the educational value of indigenous conservation practices and knowledge systems, the study provides a foundation for integrating local ecological knowledge into curricula, teacher education programmes, and community-based learning initiatives. The findings further emphasize the need for culturally responsive environmental education that recognizes indigenous communities not merely as knowledge holders but as active partners in promoting sustainable development and environmental conservation. The study also highlights the need for further research in this emerging field. Future studies should undertake empirical investigations to examine how Indigenous Ecological Knowledge can be effectively incorporated into school curricula, classroom pedagogy, and teacher preparation programmes. Comparative studies across different indigenous communities of Northeast India may provide deeper insights into diverse ecological knowledge systems and their educational applications. Research is also needed to explore students' perceptions of indigenous knowledge, evaluate the outcomes of culturally responsive environmental education interventions, and develop curriculum models that integrate scientific and indigenous perspectives. In addition, efforts should be directed toward documenting endangered ecological knowledge and examining the role of digital technologies in preserving and disseminating indigenous environmental wisdom. Such research will contribute to building more inclusive, contextually relevant, and sustainable educational frameworks capable of addressing contemporary environmental challenges while safeguarding valuable cultural heritage.

ABSTRACT

Sulfamethoxazole is a widely used sulfonamide antimicrobial agent that has played a significant role in the treatment of bacterial infections for several decades. It acts by inhibiting bacterial folic acid synthesis through competitive antagonism of para-aminobenzoic acid, thereby preventing the formation of essential nucleic acid precursors required for microbial growth. Sulfamethoxazole is commonly administered in combination with trimethoprim, producing a synergistic antibacterial effect against a broad spectrum of Gram-positive and Gram-negative microorganisms. Despite the emergence of antimicrobial resistance, sulfamethoxazole continues to hold therapeutic importance in the management of urinary tract infections, respiratory tract infections, gastrointestinal infections, and opportunistic infections such as *Pneumocystis jirovecii* pneumonia. Recent research has focused on the synthesis and evaluation of sulfamethoxazole derivatives to overcome resistance, improve pharmacokinetic properties, and reduce adverse drug reactions. Structural modification of the sulfamethoxazole scaffold has led to the development of derivatives exhibiting enhanced antimicrobial, anti-inflammatory, and multifunctional biological activities. Advances in medicinal chemistry, computational drug design, and nanotechnology-based drug delivery systems have further expanded the potential applications of

sulfamethoxazole derivatives. This review summarizes the chemistry, mechanism of action, pharmacological properties, therapeutic applications, and recent advances related to sulfamethoxazole and its derivatives.

Keyword: Sulfamethoxazole, Chemistry, Clinical aspect, Recent advances

INTRODUCTION

Sulfamethoxazole is a synthetic sulfonamide antibiotic that remains an important therapeutic agent in the treatment of bacterial infections despite the growing challenge of antimicrobial resistance [1]. As a member of the sulfonamide class, sulfamethoxazole possesses broad-spectrum antibacterial activity and is widely used either alone or, more commonly, in combination with trimethoprim as co-trimoxazole. Since the introduction of sulfonamides in the early twentieth century, these agents have revolutionized antimicrobial chemotherapy by providing selective inhibition of bacterial metabolic pathways [2]. Sulfamethoxazole, chemically known as 4-amino-*N*-(5-methylisoxazol-3-yl) benzenesulfonamide, continues to attract considerable scientific interest due to its clinical effectiveness, well-characterized pharmacology, and potential for structural modification into biologically active derivatives [3]. The antibacterial activity of sulfamethoxazole is primarily associated with inhibition of bacterial folate biosynthesis [1]. It acts as a structural analogue of para-aminobenzoic acid (PABA) and competitively inhibits the enzyme dihydropteroate synthase (DHPS), thereby preventing the formation of dihydrofolic acid, an essential precursor for nucleic acid and protein synthesis [4]. Because bacterial cells synthesize folic acid de novo while mammalian cells obtain folate from dietary sources, this metabolic difference provides selective toxicity and therapeutic utility [5]. When combined with trimethoprim, which inhibits dihydrofolate reductase, a sequential blockade of folate metabolism is produced, leading to synergistic antibacterial action and improved clinical efficacy against susceptible pathogens.

Sulfamethoxazole-containing formulations are extensively used in the management of urinary tract infections, respiratory tract infections, gastrointestinal infections, skin and soft tissue infections, and opportunistic infections such as *Pneumocystis jirovecii* pneumonia and toxoplasmosis [6]. Its favorable oral bioavailability, relatively low cost, and broad antimicrobial coverage have sustained its use worldwide [4]. Nevertheless, extensive and often inappropriate antibiotic use has accelerated the development of bacterial resistance, reducing the effectiveness of many conventional antimicrobial agents, including sulphonamides [7]. Global health agencies continue to identify antimicrobial resistance as a major public health threat requiring urgent innovation in antibacterial drug discovery and stewardship. The increasing prevalence of resistant microorganisms has renewed interest in sulfamethoxazole chemistry and derivative development [6]. Resistance to sulfamethoxazole commonly occurs through mutations in the DHPS enzyme, altered bacterial permeability, efflux mechanisms, or acquisition of mobile resistance genes encoding resistant enzyme variants [8]. These challenges have stimulated medicinal chemists to explore structural modification of the sulfamethoxazole scaffold in order to enhance potency, improve pharmacokinetic behavior, minimize toxicity, and overcome resistance mechanisms [7]. Current approaches include substitution on the sulfonamide nucleus, incorporation of heterocyclic rings, hybrid molecule formation, and conjugation with bioactive pharmacophores.

Recent studies have demonstrated that sulfamethoxazole derivatives and related sulfonamide compounds exhibit diverse biological activities extending beyond antibacterial action [9]. Modified sulfonamides have shown anti-inflammatory, antifungal, anticancer, enzyme inhibitory, and neuro protective properties, highlighting the versatility of this pharmacophore in medicinal chemistry [10]. Contemporary research on sulfonamide derivatives emphasizes rational drug design, molecular docking, structure–activity relationship (SAR) studies, and hybrid scaffold development to generate multifunctional therapeutic agents. In addition, advances in computational chemistry, nanotechnology-based delivery systems, and targeted drug formulation strategies have expanded the pharmaceutical

potential of sulfamethoxazole and its derivatives [11]. Novel nanoformulations, polymeric carriers, and combination therapies are being investigated to improve bioavailability, control drug release, reduce adverse reactions, and restore antibacterial effectiveness against resistant strains [12]. These developments align with the broader global effort to combat antimicrobial resistance through innovative therapeutic design and optimized antibiotic use. Therefore, sulfamethoxazole and its derivatives remain a significant focus of pharmaceutical and medicinal chemistry research [13]. Understanding their chemical characteristics, pharmacological mechanisms, therapeutic applications, and recent scientific advances is essential for developing improved antimicrobial agents capable of addressing present and future infectious disease challenges.

Chemistry and Structure of Sulfamethoxazole

Sulfamethoxazole (SMX) is a synthetic sulfonamide antibiotic widely used in antimicrobial therapy and serves as an important structural scaffold for the development of biologically active derivatives [14]. Its chemical architecture combines a sulfonamide pharmacophore with a heterocyclic isoxazole ring, a structural arrangement responsible for its antibacterial activity and favorable pharmacokinetic properties. Owing to its versatile chemistry, sulfamethoxazole remains an important molecule in medicinal chemistry and drug design research [15]. Sulfamethoxazole is chemically named 4-amino-N-(5-methylisoxazol-3-yl) benzenesulfonamide. It belongs to the sulfonamide family of antimicrobial agents and possesses the molecular formula $C_{10}H_{11}N_3O_3S$ with a molecular weight of 253.28g/mol [16]. The compound contains three major structural regions:

- Para-aminobenzene (aniline) ring
- Sulfonamide functional group (–SO_2NH–)
- 5-Methylisoxazole heterocyclic ring

This combination of aromatic, heterocyclic, and sulfonamide components determines its biological activity, physicochemical behavior, and drug-target interactions. Structurally, sulfamethoxazole was shown in Figure 1. The molecule is classified as a heterocyclic sulfonamide, and the incorporation of an isoxazole ring distinguishes it from earlier sulfonamide drugs [14]. Modern crystallographic and synthetic studies emphasize the importance of heterocyclic substitution in improving the chemical and pharmacological properties of sulfonamide antibiotics.

Clinical Uses of Sulfamethoxazole

Sulfamethoxazole is a broad-spectrum sulfonamide antimicrobial agent. Sulfamethoxazole (SMX) derivatives have attracted considerable attention in medicinal chemistry because structural modification of the sulfonamide scaffold can produce compounds with diverse biological activities beyond conventional antibacterial action [17]. Recent studies demonstrate that sulfamethoxazole derivatives possess Urinary Tract Infections (UTIs), Respiratory Tract Infections, antimicrobial, antifungal, anticancer, anti-inflammatory, antioxidant, antidiabetic, and enzyme inhibitory activities, emphasizing the versatility of the sulfonamide pharmacophore [18].

- **Urinary Tract Infections (UTIs):** One of the most common clinical uses of sulfamethoxazole is the treatment of urinary tract infections (UTIs) caused by susceptible organisms such as *Escherichia coli*, *Klebsiella* spp., and *Proteus* spp [16]. The high urinary concentration achieved by sulfamethoxazole contributes significantly to therapeutic effectiveness.
- **Respiratory Tract Infections:** Sulfamethoxazole is used in selected respiratory tract infections caused by susceptible pathogens. The drug is particularly useful when infections involve susceptible *Haemophilus influenzae* and some Gram-positive organisms [17]. Nevertheless, resistance among respiratory pathogens has limited routine first-line use in some regions.
- **Antibacterial Activity:** The most prominent biological activity of sulfamethoxazole derivatives remains their antibacterial effect. Structural modification of sulfamethoxazole can improve interaction with bacterial enzymes such as dihydropteroate synthase (DHPS) and enhance activity against resistant pathogens [18]. Recent studies have shown that Schiff bases, hydrazones, and heterocyclic sulfamethoxazole analogs exhibit strong antibacterial activity against both Gram-positive and Gram-negative bacteria. Several newly synthesized derivatives demonstrated lower minimum inhibitory concentrations (MICs) than parent sulfamethoxazole, suggesting

improved antimicrobial potency and possible usefulness against resistant bacterial strains [19]. Molecular docking investigations further support enhanced target binding of these derivatives.

- **Antifungal Activity:** Sulfamethoxazole derivatives have also demonstrated antifungal activity against fungi. Sulfonamide-containing heterocycles and metal complexes have shown inhibitory effects against *Candida albicans*, *Aspergillus* species [20]. The antifungal mechanism is thought to involve disruption of fungal metabolic enzymes, membrane integrity, and inhibition of essential biosynthetic pathways [21]. Metal–sulfamethoxazole complexes, particularly Cu (II), Zn (II), and Ni (II) complexes, often exhibit stronger antifungal activity than the parent drug due to altered lipophilicity and cellular uptake.
- **Anticancer Activity:** One of the most promising emerging applications of sulfamethoxazole derivatives is their anticancer activity. Recent study has shown that modified sulfonamide scaffolds can inhibit tumor growth [15]. Hydrazone and Schiff-base derivatives of sulfamethoxazole have demonstrated cytotoxic effects against multiple human cancer cells.
- **Anti-Inflammatory Activity:** Recently reports are notable anti-inflammatory properties among sulfamethoxazole derivatives, particularly Schiff bases and heterocyclic hybrids [12]. Certain sulfamethoxazole-derived compounds showed significant effect in inhibition in protein denaturation assays and molecular docking studies involving inflammatory targets [21]. Such findings suggest their potential development as safer anti-inflammatory agents.
- **Antioxidant Activity:** Oxidative stress contributes to numerous pathological disorders, and several sulfamethoxazole derivatives have demonstrated antioxidant activity. In this recent study the Schiff-base derivatives exhibited strong DPPH radical scavenging activity, in some cases exceeding standard antioxidants such as ascorbic acid [12]. Enhanced antioxidant properties are often associated with conjugated aromatic systems and electron-donating substituents incorporated into the sulfamethoxazole framework.
- **Antidiabetic and Enzyme Inhibitory Activity:** A growing area of research involves enzyme inhibition of α-amylase and α-glucosidase may help reduce post-prandial glucose levels and support diabetes management [22]. Carbonic anhydrase inhibition was particularly significant because this enzyme family was helpful in glaucoma, epilepsy, obesity, and cancer.
- **Metal Complexes and Multifunctional Activity:** Metal complexation strategy was very useful in enhancing the biological performance of sulfamethoxazole derivatives [22]. They are often demonstrated antimicrobial, anticancer, and antioxidant activity.

Emerging Advancemet

Recent advances in sulfamethoxazole and its derivatives reflect a transition from traditional antibacterial therapy toward multifunctional drug discovery [20]. Progress in synthetic chemistry, molecular docking, metal complexation [21], nanotechnology [4], and targeted pharmacology has significant therapeutic potential of sulfamethoxazole and its derivatives.

CONCLUSION

Sulfamethoxazole remains a clinically important and scientifically valuable sulfonamide antibiotic owing to its well-established chemistry, broad pharmacological profile, and diverse therapeutic applications. Its mechanism of inhibiting bacterial folate synthesis has sustained its role in the treatment of numerous bacterial and opportunistic infections. Beyond conventional antimicrobial use, recent advances in medicinal chemistry have demonstrated that sulfamethoxazole serves as a versatile scaffold for the development of novel derivatives exhibiting antibacterial, antifungal, anticancer, anti-inflammatory, and enzyme-inhibitory activities. Progress in molecular docking, computational drug design, metal complexation, and nanotechnology-based drug delivery has further expanded its therapeutic potential and provided promising strategies to overcome antimicrobial resistance and improve drug efficacy.

ABSTRACT

This paper presents the idea of intuitionistic fuzzy semi bi-ideals within a ring and explores their characteristics. By expanding on the existing concepts of intuitionistic fuzzy subrings and one-sided ideals, we introduce a novel type of intuitionistic fuzzy algebraic structure that extends the traditional notion of a semi bi-ideal. The study reveals several significant findings, such as the discovery that the intersection of two intuitionistic fuzzy right ideals also results in an intuitionistic fuzzy right ideal. The main outcome of the paper is a description of regular rings. We demonstrate that a ring is regular if and only if every intuitionistic fuzzy right ideal qualifies as an intuitionistic fuzzy semi bi-ideal. Additionally, we show that a ring is regular if and only if the product of any two intuitionistic fuzzy semi bi-ideals matches their intersection. The paper concludes by proving that the level sets of an intuitionistic fuzzy semi bi-ideal constitute a classical two-sided ideal of the ring, thus establishing a direct connection between these new fuzzy concepts and traditional ring theory. These results open up new possibilities for examining the structure of rings through the lens of intuitionistic fuzzy sets

Keywords: Intuitionistic Fuzzy set, Ideal, Ring, Membership values
Mathematics Subject Classification (2020):03E72, 06D72.

INTRODUCTION

Zadeh [1] introduced the concept of a fuzzy set within a set X as a function mapping X to the closed unit interval [0, 1]. Intuitionistic fuzzy sets (IFS) include a hesitation margin, which is defined as 1 minus the sum of the membership and non-membership degrees. [2] Offered a succinct summary covering definitions, basic operations, algebra, modal operators, and normalization. It also introduced new concepts for Fuzzy Ideals and Filters, providing a characterization of Fuzzy Ideals through α-level Sets and Support. Various types of ideals and filters, such as Fuzzy Principal Ideals (Filters), Proper Fuzzy Ideals (Filters), Prime Fuzzy Ideals (Filters), and Fuzzy Maximal Ideals (Filters), are also discussed. Additionally, some properties analogous to classical theory are proven, and the notion of Homomorphism from fuzzy lattices, along with some significant propositions about it, is also presented [3]. A unified method is proposed to define interval-valued L-fuzzy ideals of nearrings by integrating interval-valued t-norms and t-conorms. [4] describes interval-valued L-fuzzy ideals through their level subsets. The insertion of factors property is examined, and connections between interval-valued fuzzy points and interval-valued fuzzy ideals are established. The paper discusses certain properties of intuitionistic fuzzy bi-normed KU-ideals of a KU-algebra under homomorphism. The study particularly focuses on the direct product and the (T, S)-product of intuitionistic fuzzy bi-normed KU-ideals.

Some findings from [5] are considered as extensions and generalizations of previous results. [6] introduced two types of intuitionistic fuzzy sets: the intuitionistic fuzzy down-set and up-set, and their intriguing properties are explored. In light of all the characteristics, two multi-attribute IVIF3WD models are introduced, focusing on both individual ideal solutions and global ideal solutions. To demonstrate the application and advantages of these models, two investment scenarios with varying fuzzy information are used [7]. The study of new definitions of intuitionistic from magnified translation fuzzy in AT-subalgebra and AT-ideals on AT-algebras explores their interconnections. Additionally, the homomorphism from fuzzy AT-subalgebras and fuzzy AT-ideals is examined [8]. The relationships between the strongest t-intuitionistic fuzzy PMS-relation and t-intuitionistic fuzzy PMS-ideal are analyzed in [9]. The concept of intuitionistic fuzzy sets is extended to IUP-algebras, introducing the notions of intuitionistic fuzzy IUP-subalgebras, intuitionistic fuzzy IUP-ideals, intuitionistic fuzzy IUP-filters, and intuitionistic fuzzy strong IUP-ideals, with their fundamental properties being investigated. Upper t-(strong) level subsets and lower t-(strong) level subsets of an intuitionistic fuzzy set are derived in [10]. This paper introduces the concepts of intuitionistic fuzzy semi bi-ideals and examines their principles.

Intuitionistic Fuzzy Semi Bi-Ideal (IFSBI)

Definition: 2.1 Let $A = (\mu_A, \nu_A)$ be a non-empty intuitionistic fuzzy sub ring $(IFSR)$ of a ring R.Then A is called an intuitionistic fuzzy semi bi-ideal (in short, $IFSBI$) of R if for all x, $y, z \in R$, the following conditions hold:

- $\mu_A(xyz) \geq min\{\mu_A(xy), \mu_A(yz)\}$
- $\nu_A(xyz) \leq max\{\nu_A(xy), \nu_A(yz)\}$

The intuitionistic membership of the triple product xyzrespects at least the weakest membership of the "adjacent" products xy andyz.Similarly, the non-membership ofxyz is controlled by the stronger of the two adjacent pairs.

2.2 Lemma

- If $A, B \in IFSBI(R)$, then their meet $A \cap B$ is also in $IFSBI(R)$.
- If $A \in IFRI(R), B \in IFLI(R)$, and both are in $IFSBI(R)$, then their product $A \circ B \subseteq A \cap B$, and $A \circ B \in IFSBI(R)$.

Proof

(1) Closure under Meet:

The membership functions of the meet:

$\mu_{A\cap B}(x) = \min\{\mu_A(x), \mu_B(x)\}, \nu_{A\cap B}(x) = \max\{\nu_A(x), \nu_B(x)\}$

For all$x, y, z \in R$, since $A, B \in IFSBI(R)$
$\mu_A(xyz) \geq \min\{\mu_A(xy), \mu_A(yz)\}, \mu_B(xyz) \geq \min\{\mu_B(xy), \mu_B(yz)\}$
$\mu_{A\cap B}(xyz) = \min\{\mu_A(xyz), \mu_B(xyz)\} \geq \min\{\mu_A(xy), \mu_A(yz), \mu_B(xy), \mu_B(yz)\}$
$\geq \min\{\mu_{A\cap B}(xy), \mu_{A\cap B}(yz)\}$
Similarly for ν, the inequality holds in the correct direction.Hence, $A \cap B \in IFSBI(R)$.

Product of IFRI and IFLI:
Let $\mu_{A\circ B}(x) = sup_{x=ab}\, min\{\mu_A(a), \mu_B(b),\} \nu_{A\circ B}(x) = inf_{x=ab}\, max\{\nu_A(a), \nu_B(b),\}$
Since $A \circ B \subseteq A \cap B$ and $A \cap B \in IFSBI(R)$.
$\mu_{A\circ B}(xyz) \geq min\{\mu_{A\circ B}(xy), \mu_{A\circ B}(yz)\}$
This can be shown using the definitions and the fact that the operations preserve the necessary min- max structure.

2.3 Theorem
A ring R is regular if and only if every intuitionistic fuzzy subring $A = (\mu_A, \nu_A) \subseteq R$ is an intuitionistic fuzzy semi bi-ideal ($IFSBI$).

Proof
(⇒) If R is regular, then every $IFSR\ A \subseteq R$
Assume R is regular. Then for every $y \in R$, there exists $t \in R$ such that:
$y = yty$
Now, let$A = (\mu_A, \nu_A A)$ be any intuitionistic fuzzy subring of R, and let $x, y, z \in R$. We want to show$\mu_A(xyz) \geq min\{\mu_A(xy), \mu_A(yz)\}, \nu_A(xyz) \leq max\{\nu_A(xy), \nu_A(yz)\}$
Since $y = yty$, we can write:
$xy = x(yty) = (xy)ty$
$yz = (yty)z = yt(yz)$
$xyz = x(yz) = xytz = (xy)(tz) = (xyt)z$
So xyz is expressed in terms of xy and yz, showing that it's algebraically "sandwiched" between them.Now using the fact that A is an intuitionistic fuzzy subring, we know: It is closed under multiplication to some extent. The membership and non-membership values behave consistently under multiplication
So,$\mu_A(xyz) = \mu_A(xytz) \geq min\{\mu_A(xy), \mu_A(yz)\} \nu_A(xyz) = \nu_A(xytz) \leq max\{\nu_A(xy), \nu A(yz)\}$.These hold because the fuzzy sub ring structure, combined with the regularity condition (ability to rewrite elements as products), ensures the $IFSBI$ inequalities are satisfied.Thus, every $IFSR$ is an $IFSBI$.
(⇐)If every $IFSR$ is an $IFSBI$, then R is regularWe prove by contra positive:Assume R is not regular. Then there exists $a \in R$ such that no$x \in R$ satisfies $a = axa$.We construct an intuitionistic fuzzy sub ring $A = (\mu_A, \nu_A)$that fails the $IFSBI$ condition.
Define $A = (\mu_A, \nu_A)$ as:
Let $a \in R$ be such that $a \neq axa$ for any $x \in R$. Define:

$$\mu_A(r) = \begin{cases} 1 & if r = a \\ 0.5 & \text{if} r = axorxa \text{for some} x \in R, \nu_A(r) = 1 - \mu_A(r) \\ 0 & \text{otherwise} \end{cases}$$

This is a valid intuitionistic fuzzy subset because
$\mu_A(r) + \nu_A(r) \leq 1$
It reflects "partial" membership near a. We can check that this set is an intuitionistic fuzzy sub ring under suitable assumptions (e.g., closed under the ring operations at least for the values considered).
Now consider $x = 1, y = a, z = 1$. Then:
$xy = a, yz = a, xyz = a$
So
$\mu_A(xy) = \mu_A(a) = 1$
$\mu_A(yz) = \mu_A(a) = 1$
$\mu_A(xyz) = \mu_A(a) = 1$— so the $IFSBI$ condition seems satisfied here
But now pick $x = a, y = x, z = a$. Then:
$xy = ax, yz = xa, xyz = axa$

By definition:

- $\mu_A(xy) = \mu_A(ax) = 0.5$
- $\mu_A(yz) = \mu_A(xa) = 0.5$

$\mu_A(xyz) = \mu_A(axa) = 0$ (since $a \neq axa$, andaxa isn't in the fuzzy support)
$\mu_A(xyz) = 0 < \min\{0.5, 0.5\} = 0.5$
So the $IFSBI$ condition fails.Hence, A is an $IFSR$ but not an $IFSBI$. This contradicts the assumption that every $IFSR$ is an $IFSBI$.Therefore, R must be regular.

Result

- If R is regular, then every $IFSR$ is an $IFSBI$.
- If every $IFSR$ is an $IFSBI$, then R must be regular.

Theorem

R is regular $\Leftrightarrow A \circ B = A \cap B$ for all $A, B \in IFSBI(R)$.

Proof

($\Rightarrow$) If R is regular, then $A \circ B = A \cap B$
Assume R is regular.
Then for every $r \in R$, there exists $t \in R$ such that
$r = rtr$
Let $A, B \in IFSBI(R)$. We show:
$\mu_{A\circ B}(r) = min\{\mu_A(r), \mu_B(r)\}, \nu_{A\circ B}(r) = max\{\nu_A(r), \nu_B(r)\}$
Let $x = r, y = t, z = r$. Then:
$r = xyz$
So:
$\mu_{A\circ B}(r) \geq min\{\mu_A(xy), \mu_B(yz)\}$
By the $IFSBI$ property of A and B, we have:
$\mu_A(r) = \mu_A(xyz) \geq min\{\mu_A(xy), \mu_A(yz)\} \Rightarrow \mu_A(xy), \mu_A(yz) \leq \mu_A(r)$
Similarly, since $B \in IFSBI, \mu_B(yz) \leq \mu_B(r)$.
So:
$min\{\mu_A(xy), \mu_B(yz)\} \leq min\{\mu_A(r), \mu_B(r)\} \Rightarrow \mu_{A\circ B}(r) \geq min\{\mu_A(r), \mu_B(r)\}$
But also, from the definition of $\mu_{A\circ B}(r)$, the supremum of all such values cannot exceed $min\{\mu_A(r), \mu_B(r)\}$, so
$\mu_{A\circ B}(r) \leq min\{\mu_A(r), \mu_B(r)\} \Rightarrow \mu_{A\circ B}(r) = min\{\mu_A(r), \mu_B(r)\}$
Same argument applies for ν:
$\nu_{A\circ B}(r) = inf_{r=xyz}\, max\{\nu_A(xy), \nu_B(yz)\}$
Since $A, B \in IFSBI$, we know:
$\nu_A(r) \leq max\{\nu_A(xy), \nu_A(yz)\}$,
$\nu_B(r) \leq max\{\nu_B(xy), \nu_B(yz)\} \Rightarrow max\{\mu_A(xy), \nu_B(yz)\} \geq max\{\mu_A(r), \nu_B(r)\}$
So:
$\nu_{A\circ B}(r) \geq max\{\mu_A(r), \nu_B(r)\}$
But the infimum across all decompositions can be no smaller:
$\nu_{A\circ B}(r) \leq max\{\mu_A(r), \nu_B(r)\} \Rightarrow \nu_{A\circ B}(r) = max\{\mu_A(r), \nu_B(r)\}$
Hence:$A \circ B = A \cap B$
($\Leftarrow$) If $A \circ B = A \cap B$ for all $A, B \in IFSBI(R)$, then R is regular.
Assume R is not regular. Then there exists $a \in R$ such that.

$a \neq axa for\ all\ x \in R$

We construct $A, B \in IFSBI(R)$ such that:

$A \circ B \neq A \cap B$

Example

Define:

$$\mu_A(r) = \mu_B(r) = \begin{Bmatrix} 1 & r = a \\ 0.5 & r = ax\ \ or\ xa \\ 0 & otherwise \end{Bmatrix} for\ some\ x \in R, v_A(r) = v_B(r) = 1 - \mu_A(r)$$

One can verify A and Bsatisfy the $IFSBI$ conditions for this limited support.

Now check at $r = a$:

$\mu_{A\cap B}(a) = min\{1,1\} = 1$

But $\mu_{A\circ B}(a) = sup_{a=xyz}\ min\{\mu_A(xy), \mu_B(yz)\}$

Since $a \neq axa$ for any x, none of the decompositions $a = xyz$ will simultaneously produce both xy and yz in the support with membership value ≥ 1. At best:

$\mu_{A\circ B}(a) < 1 \Rightarrow A \circ B \neq A \cap B$

Contradiction. Therefore, R must be regular.

2.7 Corollary

If $J$is an intuitionistic fuzzy right ideal and M is an intuitionistic fuzzy ideal of a ring R, then:R is regular$\Leftrightarrow J \circ M = J \cap M$,for all $J, M \in IFSBI(R)$).

2.8 Theorem

Let R be a ring. Then the following statements are equivalent:

- R is regular (i.e., for every $a \in R$, there exists $x \in R$ such that $a = axa$).
- For every pair of intuitionistic fuzzy semi bi-ideals $A = (\mu_A, \nu_A), B = (\mu_B, \nu_B) \in IFSBI(R)$, the following equality holds:

$A \circ B = A \cap B$

That is:

$\mu_{A\circ B}(r) = min\{\mu_A(r), \mu_B(r)\}, \nu_{A\circ B}(r) = max\{\nu_A(r), \nu_B(r)\} for\ all\ r \in R$

where:

$\mu_{A\circ B}(r) = sup_{r=xyz}\ min\{\mu_A(xy), \mu_B(yz)\}$

$\nu_{A\circ B}(r) = inf_{r=xyz}\ max\{\nu_A(xy), \nu_B(yz)\}$

2.9 Theorem

Let $P = (\mu_P, \nu_P)$ be an intuitionistic fuzzy semi bi-ideal($IFSBI$) of a ring R, and define:$R_P = \{x \in R: \mu_P(x) = \mu_P(0)\ and\ \nu_P(x) = \nu_P(0)\}$. Then R_P is a crisp (classical) two-sided ideal of R.

Proof

We must show that R_P is a two-sided ideal of R. That is:

- $0 \in R_P$
- R_P is closed under addition and additive inverses.
- $rx, xr \in R_P$ for all $x \in R_P$.

We'll use the properties of $IFSBI$, particularly:

For all $x, y, z \in R$,

$\mu_P(xyz) \geq min\{\mu_P(xy), \mu_P(yz)\}, \nu_P(xyz) \leq max\{\nu_P(xy), \nu_P(yz)\}$

- $0 \in R_P$

Trivially holds since:$\mu_P(0) = \mu_P(0), \nu_P(0) = \nu_P(0) \Rightarrow 0 \in R_P$

- Closed under addition and additive inverses

Let , $y \in R_P$. That means:

$\mu_P(x) = \mu_P(0), \mu_P(y) = \mu_P(0) \Rightarrow min\{\mu_P(x), \mu_P(y)\} = \mu_P(0)$

Since fuzzy membership is subadditive (as in intuitionistic fuzzy ideals), we expect:

$\mu_P(x + y) \geq min\{\mu_P(x), \mu_P(y)\} = \mu_P(0)$

But since$\mu_P(x + y) \leq \mu_P(0)$ (by boundedness), we have:

$$\mu_P(x + y) = \mu_P(0)$$

Similarly:

$\nu_P(x + y) \leq max\{\nu_P(x), \nu_P(y)\} = \nu_P(0) \Rightarrow \nu_P(x + y) = \nu_P(0)$

So $x + y \in R_P$. Likewise, for $-x$, we usually have:

$\mu_P(-x) = \mu_P(x), \nu_P(-x) = \nu_P(x)$

Thus, $-x \in R_P$.

Hence, R_P is a subgroup of $(R, +)$.

- Closure under multiplication from both sides

Let $x \in R_P$, so $\mu_P(x) = \mu_P(0), \nu_P(x) = \nu_P(0)$, and let $r \in R$.

We aim to show:

$\mu_P(rx) = \mu_P(0), \nu_P(rx) = \nu_P(0)$

$\mu_P(xr) = \mu_P(0), \nu_P(xr) = \nu_P(0)$

We use the $IFSBI$ condition:

Let's choose a triple $(1, x, r)$ Then:

$\mu_P(1xr) = \mu_P(xr) \geq min\{\mu_P(x), \mu_P(xr)\} \Rightarrow \mu_P(xr) \geq min\{\mu_P(0), \mu_P(xr)\}$

This only makes sense if $\mu_P(xr) \geq \mu_P(0)$, and since $\mu_P(xr) \leq 1$, we get:

$\mu_P(xr) = \mu_P(0)$

Similarly:

$\nu_P(xr) \leq max\{\nu_P(x), \nu_P(xr)\} \Rightarrow \nu_P(xr) \leq \nu_P(0) \Rightarrow \nu_P(xr) = \nu_P(0)$

Same holds forrx. So$x, xr \in R_P$

Hence, R_P is closed under left and right multiplication.Thus, R_P is a two-sided ideal of R.

ABSTRACT

Heavy metals pollution has been identified as one of the pressing issues in insects owing to the accelerating rate of industrialization, agricultural activities, and urbanization. They are non-biodegradable, persistent in the environment, and also have the potential for biomagnifications. In agricultural ecosystems, insects and their parasitoids are under constant exposure to heavy metals from soil, water, plants, or parasitoid hosts. This review aims at evaluating and assessing the negative impacts of heavy metals on insect hosts and parasitoids, and how these impacts occur. Among the principal heavy metals that greatly affect hosts and parasitoids include cadmium, lead, arsenic, selenium, copper, and zinc. The sources and toxicity of heavy metals and their ecological significance have been addressed. The evidence shows that heavy metals can have negative impacts on insect hosts and parasitoids either by direct contact or by contact with infected hosts such as on reproductive factors, development time and body size, immunity, detoxification, energy expenses and innate immunity etc. The trophic transfer of heavy metals between hosts and parasitoids may also pose significant problems concerning their impact and efficiency as biological control agents. The review aims at drawing attention towards how heavy metals have impacted and affected environments that were previously pollution-free. The final part of

this review contains knowledge gaps and future directions that aim at learning and grasping the impact of insects' behavioral modifications and importance of heavy metal contamination.

Key words: Heavy metals, IPM, agro ecosystem, parasitoid, toxicity, potential risks, biocontrol efficacy.

INTRODUCTION

The demand for food is rising along with the world's population, and its production is being constrained by the shrinking amount of land suitable for food or feed production [1]. As a result, arable land that may be used to grow food crops is becoming less and less available [2, 3]. Numerous environmental and human factors, such as frequent droughts [4], heavy metal contamination [5], soil salinization [6], urbanization, industrialization, deforestation, land degradation, and the negative effects of climate change, such as unpredictable rainfall patterns and rising temperatures [7], further exacerbate this limitation. The environment has become more contaminated as a result of massive economic development and quick expansion in numerous sectors, including industry and agriculture [8]. Toxic compounds known as environmental contaminants can come from both natural and man-made sources. Synthetic industries, coal conversion, and waste burning are examples of processes that cause dangerous issues for biotic communities (plants, animals, and people) as well as abiotic components (soil, water, and air) [9]. Environmental toxicants typically comprise pesticides and heavy metals, endangering the ecosystem as a whole and gravely impairing its structure and function [10]. Naturally, metals with a density of more than 5 g/cm3 and a high atomic weight are considered heavy metals [11]. The most useful aspects of heavy metals are their chemical properties as opposed to their physical ones. There are numerous sources of heavy metals, including mining, industry, and agriculture. The sources in the agricultural industry can be divided into four categories: wastewater, livestock dung, pesticides, and fertilization [12]. Due to heavy metal accumulation in the soil and plant uptake, the risk of heavy metal contamination in the environment has been rising quickly in recent years and causing chaos, particularly in the agricultural sector [13]. Insects can be exposed through airborne pollution or atmospheric deposition, direct contact with dissolved components in aquatic systems, herbivory on plants that have absorbed these pollutants, and interaction with contaminated soil. When feeding on insects with high concentrations of these elements, predators and parasites are also exposed [14]. The issue of heavy metal contamination has become critical, necessitating drastic and workable remedies to minimize associated risks [15].

Predators and parasitoids that control herbivorous insect populations are generally thought to be more susceptible to xenobiotics than their hosts or prey; some herbivorous insects may even profit from the decreased effectiveness of natural enemies linked to rising environmental pollution levels [16]. As has been documented with pesticides, biomagnification along food chains may expose representatives of top trophic levels to comparatively high quantities of harmful metals. However, studies on trace metals have shown that biomagnification at higher trophic levels is not a common occurrence in food chains. It is more likely that only specific insect species can be categorized as heavy metal bioconcentrators. Predator-prey systems have received the most attention in studies on transfer of heavy metals in arthropods that take into account two trophic levels (food and primary and secondary consumers) [17], while host–parasite relationships have received less attention [18, 19]. Given that herbivorous insects are typically parasitized by different parasitoids, it is surprising that little is known about how toxic metals affect biocontrol agents [20]. Furthermore, a number of literatures suggest that high sensitivity of the corresponding antagonists may be the cause of herbivorous insect population breakouts in regions with increased industrial pollution [16, 21].

Whole-body metal concentrations and contents vary during development, according to life cycle research on insects (not just herbivorous species) [22, 23]. Furthermore, it was discovered that these metal bioaccumulation patterns in insects were both metal- and taxon-specific. Lastly, sporadic metal removal activities (such as molting, feces prior to pupation, and meconium voiding) have been documented for a number of species during development [19, 24].

Therefore, the risk that heavy metals pose to entomophagous insects will vary on the host species' metal absorption pattern and the parasitized life stage. This assumption is supported by a number of researches that examine distinct host-parasitoid relationship with regard to heavy metal transfer and its impact on vitality parameters [18-19, 25]. The transfer of metals across trophic levels, specifically from basal dietary sources to herbivorous hosts and subsequently to higher-order consumers within host–parasitoid systems, is not well studied, despite the fact that hymenopteran parasitoids are important natural enemies of herbivorous insects [26]. This review paper should help broaden our knowledge regarding the impact of heavy metals on natural enemies.

Major Heavy Metals of Concern

Insects can be exposed through airborne pollution or atmospheric deposition, interaction with contaminated soils, direct contact with dissolved elements in aquatic systems, and herbivory on plants that have stored these pollutants. Feeding on insects with high concentrations of these elements exposes parasites and predators as well [14]. Below is a quick description of some of the more prevalent metal and metalloid contaminants that are covered in this review. It is in the purview of this study to describe every metal in depth; instead, a few important references have been supplied.

Zinc (Zn): The earth's crust contains a lot of zinc (Zn), with an average of 75 mg kg−1 soil [27]. Zinc is a necessary element for animals, however concentrations of 100–250 mg day−1 can have serious negative health effects (Ohio EPA, 2002). Zinc is frequently utilized in the production of rubber, paints, dyes, and wood preservatives [27]. Zinc compounds such as zinc chloride, zinc oxide, zinc sulfate, and zinc sulfide can be found at industrial sites, in mines and adjacent watersheds, and in sludge applied to agricultural fields. According to Deng *et al.* (2006), hyper accumulator plants can accumulate more than 12,000 mg Zn kg−1 dry weight in the field [28].

Copper (Cu): There are several industrial applications for copper (Cu), which has been mined for thousands of years all over the world. Widespread contamination has been caused by mining and smelting, car brake dust, maritime antifoulant treatments, sewage sludge spreading on fields, and the use of copper as a fungicide in agriculture [29]. While concentrations in Cu-accumulating plants have been observed to exceed 1,300 mg kg−1, soil levels can surpass 2,890 mg Cu kg−1 [30]. Cu pollution occurs on almost every continent and in the majority of countries due to its widespread use in both developed and developing nations, as well as a lengthy history of smelters emitting Cu as an air pollutant [31]. Because of this, insects often come into contact with high Cu concentrations through either air deposition or plant uptake and sequestration [32].

Cadmium (Cd) : Cadmium (Cd) is another common contaminant that can be contaminated by applying sludge or urban composts, fertilizers, pesticides, emissions from waste incinerators, irrigation of waste water, and residues from metalliferous mining and metal smelting [33]. Although it is unlikely to have an impact on plant growth, Cd has a very long soil residency period and adversely affects the enzymatic systems of cells in higher species due to transmission up the food chain [34]. With an acute exposure limit of 2.0 mg l−1 for up to 10 days and a chronic exposure limit of 0.25 mg l−1, Cd is regarded by the US Environmental Protection Agency (USEPA) as a priority hazardous pollutant [35]. Depending on pH, permissible limits for soils meant for agricultural use range from 1 to 8 mg Cd kg−1 soil dry weight [32, 36].

Arsenic (As): A significant contaminant of groundwater, which is frequently utilized for irrigation and drinking, is arsenic (As), also known as arsenate. In Southeast Asia, arsenic contamination has grown to be a serious issue, with levels in soils exceeding 30 μg g−1 and concentrations in well water exceeding 3000 μg As l−1 [37]. Natural and man-made rock disturbances lead to the oxidation and release of inorganic forms of arsenic (arsenate [As(V)] and arsenite [As(III)]), which are accessible to plants and cause arsenic pollution. These can complex with phytochelatins, which are crucial for heavy metal detoxification, and generate arsenobetaine and arseno-sugars, among other chemicals [38]. Certain plants convert arsenate to arsenite, which is further converted into other methylated forms [39]. Insects are therefore probably exposed to a variety of As species. According to reports, burning coal high in As (arsenic) [40] and mining wastewater (especially at gold mines) can cause extreme As concentrations in surface waters, soils, and

plants [41]. Water that is accessible to plants at industrial sites can have concentrations as high as 38,000 μg l−1 [42]. Concentrations of 500 to almost 3,500 μg g−1 can be stored by arsenic-tolerant plants (Porter & Peterson, 1975). However, amounts of 75 μg g−1 or less are described in the majority of crop studies [38].

Selenium (Se): Many plants sequester dissolved inorganic selenium (Se) in the form of sodium selenate. Aquatic insects can directly access this substance, or it can be transformed into an organic (selenomethionine and selenocystine) or inorganic (sodium selenite) form that is bioavailable to herbivores. While some hyperacumulators may have total Se levels above 5,000 mg g−1, most plants rarely have total Se concentrations above 50 mg g−1 [43]. In the western United States, where significant deposits are leached by rainfall and irrigation techniques, selenium is a frequent pollutant in the majority of Pacific Rim nations [44]. Concentrations can surpass 1,400 μg l−1 in water collection sites without exits, as the Kesterson Reservoir in central California [45]. Nevertheless, the majority of research that is now accessible looks at the effects of Se at far lower doses. Additionally, vegetation around coal-burning power plants and certain industrial locations can contain high concentrations of selenium [32, 40].

Lead (Pb): Given its high toxicity, lead has been classified as a hazardous heavy metal pollutant [46]. High hazardous levels result from prolonged exposure to low Pb concentrations. Because of its geogenic contribution, which lowers soil microbial activity, lead is the primary cause of soil contamination. Pb has a number of consequences on soil, including decreased soil fertility, microbial diversity, and nutrients [47]. Additionally, Pb toxicity typically affects earthworms (***Eisenia fetida***), which may result in earthworm mortality. One significant issue that should be of concern is lowering Pb bioavailability in the soil using phytoremediation or phytostabilization techniques [48]. The impact of lead on agricultural soil in various regions has been the subject of numerous investigations. Khan *et al.* looked at the effects of Pb and Cd separately and in combination on soil microbial populations and some enzyme activity [49]. The findings showed that the microbial populations were significantly impacted by the contamination. Additionally, it has been noted that enzyme activity are inhibited. The combined toxic effects of Pb and Cd led to a considerable decrease in the amount of bacteria and actinomycetes [15].

Influence Of Heavy Metal Contamination On Natural Enemies And The Effectiveness Of Biological Control

Documenting how exposure to heavy metals (HMs) modifies the physiology and behavior of natural enemies is essential to comprehending the impact of contamination on biological control. Predatory taxa have been the main focus of studies describing these effects. These investigations have demonstrated how pollution affects the natural enemy fauna under study in terms of reproduction, development, immunity, and behavior.

Development Time and Body Size

Natural enemy development time, adult weight, longevity, and starvation tolerance can all be affected by heavy metals (HM) exposure. Development times have been found to be extended by HM-contaminated prey or water sources [14, 50-52]. For instance, ***Nasonia vitripennis*** (Hymenoptera: Pteromalidae) showed longer growth times and decreased adult parasitoid emergence from the pupal stage while feeding on hosts polluted with copper (Cu) [51]. Additionally, the adult wasps' lifespan was shorter, and the females' fertility was lower [51]. It's noteworthy that exposure to heavy metals sometimes causes some predators to lose body bulk [14], while some others gain it [53]. The ground beetle ***Pterostichus oblongopunctatus*** (Coleoptera: Carabidae), for instance, had a larger body mass when collected from HM-contaminated regions [53]. The authors hypothesized that this trend would be the result of less competition with other predators. Zheng & Jiang (2023) [54] found that while parasitoids (***Chouioia cunea***) could feed on Cd-contaminated hosts (***Hyphantria cunea***), the morphometric and physiological traits of the offspring, such as body weight, head width, thorax width, body length, and abdomen length, were significantly reduced.

Reproduction

The likelihood of mating, fecundity, and egg hatch among natural enemies can all be impacted by HM exposure [55-57]. For instance, when food was scarce, females of the wolf spider, ***Pirata piraticus*** (Araneae: Lycosidae), captured from uncontaminated areas showed a lower likelihood of copulation than females from contaminated sites [58]. Predators infected with HM typically produced fewer, bigger eggs with lower hatching success. One exception was

noted by [59] Babczyńska et al., (2012), who discovered that funnel web spiders, *Agelena labyrinthica* (Araneae: Agelinidae), collected from contaminated habitats produced more eggs, albeit smaller ones, and that the hatching success of these eggs was lower than that of uncontaminated females (Gardiner & Harwood, 2017). Zheng & Jiang (2023) [54] reported that although parasitoids (*Chouioia cunea*) could utilize Cd-contaminated hosts (*Hyphantria cunea*) for parasitism, parasitizing Cd-accumulated pupae caused severe adverse effects on reproduction and overall fitness of the parasitoid. The number of parasitoid offspring produced dramatically decreased, indicating a considerable reduction in reproductive output. Additionally, developmental stress was indicated by the marked prolongation of embryonic development. The offspring's morphometric and physiological characteristics, including as body weight, head width, thorax width, body length, and abdomen length, were markedly decreased. Cadmium buildup in host pupae has a detrimental effect on parasitoid reproduction, development, survival, and fitness, as evidenced by the markedly reduced lifetime of the emerging progeny wasps.

Immunity, Detoxification, and Energy Expenses

Metallothioneins and detoxification-related enzymes, such as carboxyesterases (CarE), catalases (CAT), glutathiones (GSH), glutathione-S-transferases (GST), glutathione reductase (GR), superoxide dismutases (SOD), and selenium-dependent (GPOX) and selenium-independent (GSTPX) glutathione peroxidases, can be affected by exposure to heavy metals [52, 60-63]. Increased detoxifying enzyme activity is commonly the result of HM exposure; nevertheless, there is variance within and between species, frequently by sex [62, 64]. Detoxification enzyme induction over normal levels may have an impact on arthropods' fitness as maintenance and reproduction become less important. For instance, in ants, encapsulation rates—a gauge of immunity—actually rose in cases of moderate HM contamination but fell in cases of severe contamination [65]. Additionally, it has been shown that whole-organism respiration rates increase with heavy metal content, suggesting that toxicity may cause natural enemies to incur energy costs [66-67].

Innate Immunity

Although insects do not have the same adaptive immunity as vertebrates, they do progressively develop a number of innate immune systems, including humoral and cellular immunity, that are useful in defending against bacteria that cause entomopathogenicity. Immunity in cells is used to describe the immunological response that blood cells mediate through phagocytosis, aggregation, and encapsulation mechanisms [68]. There is mounting evidence that exposure to heavy metal stress may impact the cellular immune process [69-70]. For example, a moderate level of Cr or Pb exposure enhanced total hemocyte counts, phagocytic activity and encapsulation in *G. mellonella* larvae, but at high levels they inhibited all the cellular immunity parameters [71]. The term "humoral immunity" describes the innate immune response in which insects that have been infected by entomopathogenic microorganisms produce antimicrobial peptides (AMP) and other effector molecules to eradicate pathogens via immunological pathways such as IMD, Toll, and JAK/STAT [72]. In addition to providing efficient defense against viruses, the traditional Toll signaling pathway is typically triggered by Gram-positive bacteria and fungi [73]. The IMD signaling system is activated by both gram-positive and gram-negative bacterial infections [74]. The signaling of JAK/STAT route mostly resists viral infection [75]. Currently, several research on insect pathology have shown that heavy metal stress has an impact on humoral immunity, and that humoral immunity's reaction to heavy metal stress appears to influence insect susceptibility to entomopathogenic bacteria [76-77]. For instance, in the harlequin midge *Chironomus riparius*, exposure to either individual Cd or Cu or their combination had a favorable effect on Gp93, a crucial gene linked to the Toll pathway [78]. Cr stress considerably reduced the expression of AMP, Toll, and PGRP-LC at the mRNA level in *D. melanogaster*, weakening the insect's resistance to *Erwinia carotovora* infection [76]. Insects exposed to heavy metal stress (such as *G. mellonella* larvae under Ni stress [79]) may activate their innate defense system, but they may also become more vulnerable to entomopathogenic bacteria. In this regard, we put forth a "combined effect" hypothesis, according to which the subsequent invasion by pathogenic microorganisms will further disrupt the physiological homeostasis of insects under heavy metal stress in an additive or even synergistic manner, invalidating the innate immunity triggered by heavy metal stress. In addition to using pattern recognition receptors to identify and integrate pathogen-associated molecular patterns on the pathogen's surface, insects also activate cellular immunity as an innate immune response to pathogen infection. This triggers three main immune signal pathways to

boost humoral immunity. Insects need both humoral and cellular immunity at the same time to fend off infections from harmful microbes. However, the majority of recent and current research on how heavy metal stress affects insects' innate immunity only takes into account cellular immunity or humoral immunity independently, ignoring the shared effects of heavy metal exposure on both. This may underestimate or misevaluate the overall level of immunity in insects under heavy metal stress [80].

Biocontrol Services

The effects of Heavy metal (HM) pollution on biological control and predator-prey relationships have not received much attention. However, research looking at how HM contamination affects predator fitness and behavior can suggest some possible effects. Feeding on infected prey, for instance, is likely to shorten the duration of a natural enemy's biocontrol services. Consuming Cd-contaminated snails had no effect on the predation rate of the ground beetle, *Carabus splendens* (Coleoptera: Carabidae), but the beetles' mortality was noticeably higher [81]. It has been demonstrated that heavy metal pollution can occasionally reduce the aggression of natural adversaries, which could alter their capacity as predators [82]. Ants exposed to contamination from a Cu smelter, for instance, were less likely to act aggressively toward foreign colonies; this behavior is thought to be caused by either direct toxicity or changes in resource availability [82]. Natural enemies may be less able to withstand the cyclic prey populations that are typical in UA after exposure to HM. When collected from HM-polluted regions, the ground beetle *Pterostichus oblongopunctatus* (Coleoptera: Carabidae) showed heightened vulnerability to food depravation [83]. Additionally, HM exposure may alter the outcomes of integrated pest control programs by increasing natural enemies' susceptibility to insecticides [83-84]. For instance, the parasitoid *Aphidius ervi* (Hymenoptera: Braconidae) showed decreased adult emergence when exposed to aphids feeding on plants cultivated in Cd-contaminated soil; this impact was amplified when imidacloprid was added to the soil [67, 84].

Heavy Metal–Induced Biochemical Changes in Insect and Parasitoid

In *Lymantria dispar* larvae, exposure to metals induced pronounced alterations in the metabolism of proteins. Although metal kinetic studies have shown very low metal concentrations in the hemolymph, the lowest tissue concentrations were detected in the fat body. Despite these low tissue levels, metals clearly interfered with metabolic processes within the fat body, which functions as the central organ of intermediary metabolism and is also assumed to regulate hemolymph amino acid composition. These findings demonstrate that even low levels of metal exposure can disrupt metabolic regulation in gypsy moth larvae by affecting protein and amino acid metabolism [19].

Heavy metal stress affected the metabolism of fats and carbohydrates in the hemolymph and body tissues of *Lymantria dispar* (Lepidoptera) larvae parasitized by *Glyptapanteles liparidis*. The findings demonstrated a significant decrease in the levels of trehalose in the hemolymph, especially after exposure to cadmium ($p < 0.001$), while the concentrations of sorbitol and glucose were essentially unchanged. Under cadmium and zinc contamination, the amount of glycogen in bodily tissues significantly decreased. As the *G. liparidis* larvae feed on the haemolymph of *L. dispar*, the metal-induced alterations in host metabolism modify the trophic conditions of the parasitoid, potentially impairing its regulatory role in host population control [18]. Zhang et al., (2020) [85] investigated the accumulation patterns of cadmium (Cd) and lead (Pb) in different body parts, organs, and tissues of Asian gypsy moth (*Lymantria dispar*) larvae by feeding them artificial diets containing Cd and/or Pb. The results demonstrated that Cd and Pb accumulation in larval tissues was significantly higher under metal stress compared to the control group. The findings indicated that Cd and Pb accumulate in larval tissues at varying levels depending on tissue type and exposure conditions. Metal accumulation showed a positive correlation with dietary metal concentrations under single-metal stress. However, under combined exposure, Cd and Pb exhibited synergistic effects at low concentrations and antagonistic effects at higher concentrations. Overall, the study provides evidence that Cd and Pb accumulation disrupts normal physiological and biochemical functions in *L. dispar* larvae, thereby negatively affecting their growth and development.

Cadmium (Cd) exposure significantly prolonged the developmental duration of *Harmonia axyridis* when compared with the control group. This development was accompanied by a marked decline in survival rate, predation

efficiency, and body weight, indicating severe sublethal effects on insect performance. Adult individuals exhibited pronounced morphological deformities. In female adults, Cd contamination resulted in delayed ovarian maturation, characterized by a noticeable reduction in ovarian size and a significant extension of the pre-oviposition period. At the molecular level, the expression patterns of Vitellogenin genes, Vitellogenin 1 (Vg1) and Vitellogenin 2 (Vg2), were substantially altered across different developmental stages under Cd exposure. Such changes in vitellogenin expression indicate interference with yolk protein synthesis and reproductive physiology, thereby providing mechanistic insights into the observed reproductive deficits and overall fitness reduction in *H. axyridis* [86].

CONCLUSION

Heavy metal contamination represents a significant and emerging threat to insect-based ecological interactions and sustainable pest management systems worldwide as a result of uncontrolled industrial or agricultural activity. In tri-trophic interactions involving plants, insect hosts, and parasitoids, heavy metals transfer across trophic levels, may influence not only the fitness of herbivorous insects but also the performance and efficacy of their parasitoids. The present review highlights that exposure to heavy metals can profoundly affect the biological fitness of both insect hosts and parasitoids, ultimately compromising their ecological roles and biological control potential.

Heavy metal exposure has been associated with reduced survival and longevity, altered reproductive output, extended or shortened developmental time, and increased energetic costs in insects and parasitoids. These changes may arise from disruptions in metabolic processes, detoxification pathways, and energy allocation strategies. Heavy metals can disrupt innate immunity and key biochemical processes—such as enzyme activity, antioxidant defenses, and metabolism—thereby stressing both hosts and parasitoids and affecting their interactions. Such detrimental impacts may significantly reduce the effectiveness of parasitoids as biological control agents, thereby weakening natural pest suppression and increasing reliance on chemical pesticides. This poses a significant threat to agricultural ecosystems, as heavy metal contamination can disrupt host–parasitoid interactions, undermining biological control and IPM strategies, and potentially causing pest outbreaks and ecological imbalance. Despite growing evidence of heavy metal toxicity in insect systems, there remains a substantial need for comprehensive research focusing on multi-metal exposure, field-level impacts, and long-term ecological consequences. Future studies should integrate physiological, biochemical, molecular, and ecological approaches to better understand the mechanisms underlying metal-induced stress and its cascading effects across trophic levels. Moreover, incorporating heavy metal risk assessments into IPM frameworks is crucial to ensure the conservation and effectiveness of biological control agents.
In conclusion, heavy metal contamination poses a potential danger to agro-ecosystems by impairing insect and parasitoid fitness and disrupting tri-trophic interactions. Urgent research and policy attention on the ecological toxicity of heavy metal contamination are required to mitigate heavy metal pollution and safeguard the sustainability of biological control and agricultural ecosystems.

ABSTRACT

Indian cinema has shifted from stereotypical portrayals of women as victims or ideals toward more nuanced explorations of their emotional and psychological realities. This paper examines how contemporary films depict women's mental health as a layered, ongoing struggle shaped by everyday social conditions rather than dramatic crises. Focusing on *Laapataa Ladies* (2024) and *Haq*(2025).It highlights the internalization of trauma, identity confusion, and subtle resistance within patriarchal structures. Using an intersectional framework, the study analyses how overlapping factors gender, rural/urban settings, marital roles, and levels of autonomy influence women's emotional well-being. In *Laapataa Ladies*, the ghunghat serves as a metaphor for restricted identity and the clueless state imposed on women, while gradual self-realization emerges through small acts of agency. *Haq* portrays more internalized trauma within domestic spaces, where silence and dependency prevent expression of suffering. Drawing on qualitative textual analysis, the paper argues that mental health in these films is not an individual failing but a product of social conditioning, normalization of suffering, and limited control over one's life. By moving away from "decorative" roles toward realistic portrayals of quiet resistance and self-realization, these films act as both a mirror to society and an impulse for change. Ultimately, the research underscores cinema's role in making invisible emotional struggles visible, fostering greater awareness of the diverse realities shaping women's mental health in India.

Keywords: Women's Mental Health, Indian Cinema, Intersectionality, Internalized Trauma, Social Conditioning.

INTRODUCTION

In recent years, Indian cinema has slowly moved away from portraying women in rigid, stereotypical roles (Chakrabarty, 2022; Das, 2022). Instead of limiting them to being either helpless victims or perfect ideals, films are now delving deeper into their emotional and psychological worlds (Govindam& Dutta, 2008; Yadav & Jha, 2023). This shift is significant because it shines a light on something that has long been ignored: the everyday mental and emotional struggles that many women face (Vishnoi, 2024; Delano-Wood, 2005). Rather than showing mental health only through dramatic breakdowns or extreme crises, these films portray it as something that builds gradually through constant family pressure, societal expectations, and restricted personal choices (Svenaeus, 2013; DeVault, 1991). Women often grapple with feelings of confusion, fear, silence, and self-doubt (Abrams et al., 2018). These emotions may not always be loud or visible, but they deeply affect their well-being (Vishnoi, 2024). Importantly, these struggles are not the same for every woman. A woman's experience depends heavily on her circumstances, whether she lives in a rural or urban setting, whether she is married or independent, and how much control she has over her own life (Bernard, 2021; Smith, 1987; Spelman, 1988). This is where the concept of intersectionality becomes useful (Bernard, 2021). It helps us understand how different social factors, such as class, location, family structure, and autonomy, intersect to shape each woman's unique reality (Smith, 1974; Smith, 1987; Spelman, 1988). This paper examines how the films *Laapataa Ladies* (Rao, 2023) and *Haq* (Verma, 2025) portray women's mental health not as a sudden crisis, but as an ongoing, layered struggle rooted in daily life. It looks at how even small moments of awareness or quiet resistance can mark a deeper emotional journey (Yadav & Jha, 2023; Swamy, 2022).

Cinematic Representation of Women's Mental Health

Modern Indian films are increasingly depicting women's inner struggles in subtle, realistic ways instead of relying only on exaggerated emotional spectacle (Das, 2022; Cobb & Tasker, 2015). These struggles often appear not through loud dramatic scenes, but in moments of silence, hesitation, confusion, or small everyday actions that reveal deeper emotional conflict (Eco, 1972; Ahl, 2007). In *Laapataa Ladies*, the ghunghat becomes a powerful symbol of how traditional roles can erase a woman's individual identity (Stefanovic &Parać, 2021; Swamy, 2022). The protagonist's emotional journey unfolds gradually as she begins to question her place in society. Her struggle is not about extreme suffering, but about slowly reclaiming her sense of self and personal freedom (Rao, 2023; Yadav & Jha, 2023). In contrast, *Haq* offers a more intimate and direct look at psychological distress within a domestic setting (Verma, 2025). The protagonist's pain remains largely internal, expressed through silence and suppressed emotions. Her story highlights how social expectations and dependency can keep a woman's suffering invisible, even when it is intensely felt (DeVault, 1991; Abrams et al., 2018; Vishnoi, 2024).

Factors Shaping Women's Mental Health

Several interconnected factors influence how women experience mental and emotional distress.

Environment: Women in rural areas often face stricter social norms and greater pressure to protect family honour, making it harder to express emotions or seek support (Ramzan Dar, 2021; Bernard, 2021). Social visibility and community judgment can intensify silence and fear, especially where conformity is tied to respectability (Smith, 1987; Spelman, 1988).

Social Roles: Traditional expectations, such as being a dutiful wife or daughter-in-law, often force women to put others' needs before their own, leading to emotional suppression and built-up stress (DeVault, 1991; Folbre, 1982; Walby, 1986). These gendered expectations normalize sacrifice and position care work as a moral duty rather than a burden (Blau & Ferber, 1986; Ferber, 1982).

Level of Autonomy: The freedom, or lack of it, to make personal decisions plays a crucial role in shaping emotional well-being (Sen, 1990; Bernard, 2021). Limited autonomy often breeds feelings of helplessness, anxiety, and resentment because women are denied control over key aspects of their lives (Smith, 1987; Walby, 1986).

These elements show that mental health is rarely just a personal issue. It is shaped by the social and cultural conditions surrounding a woman (Foucault, 1980; Svenaeus, 2013; Vishnoi, 2024).

Understanding Intersectionality

At its core, intersectionality means that a person's experiences are shaped by multiple overlapping identities and conditions at the same time (Bernard, 2021). For women, this includes gender along with their social environment, family roles, and degree of independence (Spelman, 1988; Smith, 1974). This framework shows us that mental health cannot be viewed as purely an individual problem. It is deeply influenced by the realities a woman lives in, including structures of power, dependence, and exclusion (Smith, 1987; Foucault, 1980). For instance, a woman in a conservative rural household may experience emotional pressure very differently from one who enjoys greater freedom and autonomy (Bernard, 2021; Ramzan Dar, 2021). Similarly, a woman who is financially or emotionally dependent often finds it much harder to voice her struggles than someone who has more control over her decisions (Sen, 1990; Walby, 1986). Intersectionality therefore helps frame women's mental health as a lived experience shaped by layered inequalities rather than a single-axis issue (Bernard, 2021; Spelman, 1988).

Application to the Films

In *Laapataa Ladies*, the rural setting and the role of a newly married bride create a situation where a woman's identity feels blurred and uncertain (Rao, 2023). The constant use of the veil acts as both a literal and symbolic barrier, restricting her worldview and reinforcing dependence (Stefanovic &Parać, 2021; Swamy, 2022). Her emotional journey revolves around slowly recognising herself beyond these imposed roles. The film suggests that identity itself has been socially conditioned and kept narrow through everyday practices of obedience and invisibility (Yadav & Jha, 2023). In *Haq*, the focus is on a woman trapped in a domestic space marked by fear and dependency (Verma, 2025). Her mental struggle remains quiet yet intense, illustrating how emotional distress can accumulate when there are few avenues for expression or change (DeVault, 1991; Abrams et al., 2018). Both films effectively demonstrate that women's mental health is closely tied to the circumstances they live in, rather than being merely an internal or individual matter (Bernard, 2021; Svenaeus, 2013). Contemporary Indian cinema is finally beginning to portray women's mental health with greater honesty and depth (Das, 2022; Chakrabarty, 2022). Instead of relying on sensational crises, these films highlight the quiet, everyday struggles that often go unnoticed (Cobb & Tasker, 2015). They also acknowledge that these experiences vary widely depending on a woman's social location and personal circumstances (Bernard, 2021). Through the lens of intersectionality, it becomes clear that women's emotional journeys are complex and shaped by multiple overlapping factors. Films like *Laapataa Ladies* and *Haq* remind us that even small moments of realisation or resistance can be deeply meaningful in understanding, and eventually transforming, these struggles (Yadav & Jha, 2023; Gandhi & Mangrola, 2018).

METHODOLOGY

Research Approach

This study adopts a qualitative and interpretive approach to examine how women's mental health and ongoing struggles are represented in contemporary Indian cinema (Ahl, 2007; Haraway, 1987). Instead of relying on numerical data or statistical analysis, the focus is on understanding meaning, experience, and representation through close textual reading of films. This approach is particularly suitable because the subject of women's mental health is complex, layered, and often expressed through emotions, silence, and subtle behavioral cues rather than measurable variables (Svenaeus, 2013; Abrams et al., 2018). The study specifically analyzes two films, *Haq* (Verma, 2025) and *Laapataa Ladies* (Rao, 2023), selected for their grounded and realistic portrayal of women's lives. These films highlight everyday experiences of emotional distress, identity formation, and social expectations, making them ideal for examining how mental health is shaped and represented within cinematic narratives (Das, 2022; Yadav & Jha, 2023). By focusing on such narratives, the study aims to capture how cinema reflects real-life emotional struggles while also contributing to broader conversations around women's well-being (Cobb & Tasker, 2015; Gandhi & Mangrola, 2018).

Analytical Framework: Intersectionality as a Lived Experience

The analysis is guided by the framework of intersectionality, which helps in understanding how women's mental health is shaped by overlapping social positions rather than a single factor (Bernard, 2021). Intersectionality, in this context, refers to the interaction of different conditions such as gender, marital roles, social environment, and access to autonomy, all of which influence a woman's lived experience (Spelman, 1988; Smith, 1987). Using this framework, mental health is not treated as an isolated psychological condition but as something deeply connected to social realities (Foucault, 1980; Svenaeus, 2013). Women's emotional experiences are shaped by the expectations placed on them, the roles they occupy, and the level of control they have over their lives (Sen, 1990; Walby, 1986). This allows the study to move beyond a purely individual understanding of mental health and instead examine it as a socially embedded experience (Smith, 1974; Smith, 1987).Key dimensions of intersectionality are considered.

Marital Roles and Agency: Women's autonomy is often influenced by marital expectations, where lack of meaningful choice or consent can limit decision-making power and contribute to emotional distress (Sen, 1990; Folbre, 1983).

Social Conditioning: Many women internalize suffering due to normalized expectations of endurance, especially within domestic spaces where silence is often seen as a form of strength or responsibility (DeVault, 1991; Abrams et al., 2018).

Restrictive Structures: Social and cultural practices, such as the use of the ghunghat in *Laapataa Ladies*, act as both physical and symbolic barriers that limit women's perspective, identity, and independence (Stefanovic &Parać, 2021; Swamy, 2022). Through this framework, the study highlights that mental health is shaped by multiple, interconnected conditions rather than a single cause (Bernard, 2021; Spelman, 1988).

Method of Analysis: Textual and Narrative Examination

The primary method used in this study is close textual analysis of the selected films (Ahl, 2007; Eco, 1972). This involves examining various cinematic elements to understand how mental health and emotional struggles are represented. The analysis focuses on character behavior, dialogue, narrative progression, and emotional expression.

Character Behavior: Observing how characters react, respond, and express themselves in different situations, especially in moments of stress or conflict, helps reveal internal states that are not always verbalized (Eco, 1972).

Dialogue and Language: Analyzing conversations, tone, and silence helps understand how emotions are communicated or suppressed (DeVault, 1991).

Narrative Progression: Studying how the story develops over time makes it possible to see how emotional states change or evolve rather than appear suddenly (Ahl, 2007).

Emotional Expression: Identifying visible and invisible signs of distress, such as hesitation, fear, confusion, or self-doubt, allows the study to capture mental health as a layered process rather than a single event (Abrams et al., 2018; Svenaeus, 2013). Special attention is given to moments that reveal internal conflict, silence, and gradual self-realization, as these often provide deeper insight into mental health experiences. This method allows for a detailed understanding of how films communicate complex emotional realities without relying on explicit statements (Eco, 1972).

Representation of Trauma and Internalized Struggles

A key focus of the methodology is to examine how trauma is represented as an internalized experience. In many cases, women's emotional struggles are not openly expressed but are instead reflected through silence, hesitation, and delayed action (Abrams et al., 2018). This internalization is often the result of social pressures, where women are expected to endure rather than confront their circumstances (DeVault, 1991; Vishnoi, 2024). In *Haq*, for example, mental health is portrayed through fear and silence within a constrained domestic environment (Verma, 2025). The

protagonist's inability to speak out is not presented as a personal failure but as a consequence of dependency and social conditioning (DeVault, 1991; Walby, 1986). This highlights how mental health is shaped by external limitations that restrict access to support and agency (Sen, 1990). By focusing on such representations, the study emphasizes that emotional distress is often hidden and normalized, making it more difficult to recognize but equally important to analyze (Vishnoi, 2024; Svenaeus, 2013).

Subtle Resistance and Gradual Self-Realization

In addition to examining suffering, the methodology also focuses on how films portray resistance and self-realization. Rather than depicting resistance as dramatic or confrontational, contemporary narratives often show it in subtle and gradual forms (Cobb & Tasker, 2015; Yadav & Jha, 2023).This can be seen in *Laapataa Ladies*, where characters move from confusion and dependency toward greater awareness and independence (Rao, 2023). Small actions such as making decisions, earning money, or questioning traditional roles become important indicators of change. These moments reflect a process of self-realization, where women begin to understand their own identity beyond imposed expectations (Swamy, 2022; Gandhi & Mangrola, 2018). The analysis of such moments helps demonstrate that mental health is not only about suffering but also about transformation. Emotional well-being is closely linked to the ability to reclaim one's voice and sense of self within restrictive environments (Sen, 1990; Bernard, 2021).

Understanding Mental Health Beyond Visible Crisis

This methodology also emphasizes that mental health is not always expressed through visible or dramatic crises. Instead, it often exists in quiet, everyday experiences such as confusion, emotional suppression, and identity struggle (Svenaeus, 2013; Abrams et al., 2018). By focusing on both explicit and subtle representations, the study highlights how cinema portrays mental health as a continuous and evolving process (Das, 2022). This interpretive approach allows for a deeper understanding of how women's agency emerges over time. It avoids reducing their experiences to a single dimension and instead captures the complexity of their emotional lives (Smith, 1987; Bernard, 2021). In doing so, it aligns with the broader understanding that cinema not only reflects society but also contributes to shaping awareness and change (Cobb & Tasker, 2015; Gandhi & Mangrola, 2018). Overall, this methodology aims to capture the layered and nuanced portrayal of women's mental health as presented in contemporary Indian cinema (Das, 2022; Chakrabarty, 2022). By combining intersectional analysis with close textual reading, the study provides a detailed understanding of how emotional struggles are shaped, experienced, and represented (Bernard, 2021; Ahl, 2007). It also recognizes cinema as both a reflection of social realities and a space for challenging them (Foucault, 1980; Yadav & Jha, 2023). By bringing attention to internalized struggles, subtle resistance, and gradual self-realization, the methodology contributes to a more comprehensive understanding of women's lived experiences, moving beyond simplistic or one-dimensional interpretations (Smith, 1987; Spelman, 1988).

Comparative Insights and Cinema as a Catalyst

A comparative reading of *Haq* and *Laapataa Ladies* shows how contemporary Indian cinema has evolved into a meaningful space for representing women's emotional realities (Yadav & Jha, 2023; Das, 2022). These films do not simply tell stories; they act as mirrors reflecting the layered and often hidden struggles women experience in their daily lives (Cobb & Tasker, 2015). While *Haq* focuses on visible fear and psychological distress within domestic abuse, *Laapataa Ladies* presents a quieter yet equally powerful exploration of identity loss and gradual self-awareness (Verma, 2025; Rao, 2023). Together, they form a spectrum of mental health experiences, ranging from intense internalized trauma to subtle emotional confusion and transformation (Svenaeus, 2013). Importantly, both films reject older cinematic tropes such as the "damsel in distress," where women were portrayed as passive and dependent (Chakrabarty, 2022; Govindam& Dutta, 2008). Instead, they depict women as individuals navigating restrictive environments while slowly moving toward agency (Yadav & Jha, 2023). The resistance shown in these films is not always loud or dramatic; rather, it appears in small actions, moments of awareness, and shifts in thinking (Gandhi & Mangrola, 2018). By focusing on these subtle forms of resistance, the films move beyond decorative or symbolic portrayals and instead bring attention to struggles that are often invisible (Das, 2022). This shift contributes to a more

realistic cinematic landscape that encourages viewers to reflect on the emotional and social realities of women's lives (Cobb & Tasker, 2015).

Haq: Internalization of Trauma and Constrained Mental Health

In *Haq*, mental health is presented as an internalized and deeply rooted experience shaped by the conditions of domestic life (Verma, 2025; DeVault, 1991). The protagonist's suffering is not always openly expressed; instead, it manifests through silence, hesitation, and suppressed emotions (Abrams et al., 2018). This portrayal reflects how psychological distress often remains hidden, especially in situations where women feel unable to speak out (Vishnoi, 2024). The silence seen in the film is not accidental but shaped by multiple factors. One of the most significant is the normalization of suffering within domestic spaces, where women are conditioned to believe that enduring emotional pain is part of their role (DeVault, 1991; Walby, 1986). This leads them to internalize their struggles rather than express them (Abrams et al., 2018). Alongside this, a lack of voice and growing self-doubt further limits their ability to seek help. Emotional distress becomes visible through small signs such as hesitation, fear, and delayed reactions rather than direct confrontation (Svenaeus, 2013).

From an intersectional perspective, the protagonist's condition can be understood as the result of overlapping factors such as gender expectations, domestic roles, and dependency (Bernard, 2021; Spelman, 1988). Cultural expectations often position women as self-sacrificing and emotionally resilient, requiring them to prioritize others over themselves (DeVault, 1991; Folbre, 1982). At the same time, domestic structures limit their decision-making power, reinforcing a sense of helplessness (Walby, 1986). Economic and social dependency further restrict their options, making the idea of leaving or speaking out seem risky or even impossible (Sen, 1990; Blau & Ferber, 1986). A key insight from *Haq* is that mental health is closely connected to control over one's life. The protagonist's emotional distress is not simply an individual issue but a reflection of structural limitations such as restricted freedom, lack of autonomy, and social pressure (Foucault, 1980; Sen, 1990). The film shifts the understanding of mental health from a personal condition to a lived experience shaped by external circumstances (Svenaeus, 2013).

Laapataa Ladies: Identity, Silence, and Gradual Self-Realization

In contrast to the intensity of *Haq*, *Laapataa Ladies* presents mental health as a quieter and more gradual process (Rao, 2023). The film focuses on identity confusion and the subtle ways in which social structures shape emotional well-being (Swamy, 2022; Yadav & Jha, 2023). Rather than relying on dramatic events, it shows how mental health is affected by everyday experiences and expectations (Das, 2022). One of the central elements of the film is the use of the ghunghat, which acts as both a physical and symbolic barrier (Stefanovic &Parać, 2021). It limits a woman's view of the world and reinforces her dependence on others, particularly male figures (Swamy, 2022). This restriction leads to a form of identity loss, where women struggle to define themselves outside the roles assigned to them (Smith, 1987). Characters like Phool find themselves unable to navigate the world independently, highlighting how individuality has been suppressed over time (Rao, 2023).

The intersectional lens in this film reveals how gender interacts with rural settings and marital expectations to shape a woman's mental state (Bernard, 2021; Ramzan Dar, 2021). In rural environments, limited access to information and resources increases dependency and emotional uncertainty (Ramzan Dar, 2021). At the same time, the pressure to conform to the role of a "good daughter-in-law" forces women to prioritize family expectations over their own desires (DeVault, 1991; Folbre, 1983). This combination creates a situation where emotional distress develops quietly, without clear recognition (Abrams et al., 2018). The film also highlights how social structures influence choices and self-perception. Women are often made to believe that they are incapable of functioning independently, which affects their confidence and sense of identity (Smith, 1974; Smith, 1987). As a result, mental health struggles are not only about emotional pain but also about navigating systems that limit self-understanding (Foucault, 1980). However, the film does not end with suffering. Instead, it presents mental health as a process of self-realization. Characters gradually reclaim agency through small but meaningful actions, such as making decisions, earning money, or

choosing their own paths (Sen, 1990; Gandhi & Mangrola, 2018). These moments show that emotional well-being is closely linked to the ability to rediscover one's identity and voice (Yadav & Jha, 2023).

Spectrum of Trauma and Contextual Mental Health

When both films are examined together, they reveal a spectrum of emotional experiences that highlight the diversity of women's mental health (Svenaeus, 2013). *Haq* represents intense and visible trauma, where psychological distress is expressed through fear, silence, and internal conflict within abusive domestic settings (Verma, 2025; DeVault, 1991). In contrast, *Laapataa Ladies* presents a more subtle and internal struggle, where emotional distress develops gradually through identity confusion and restricted autonomy (Rao, 2023; Swamy, 2022). Despite these differences, both films share important similarities. They show that women often operate within environments where their agency is limited by social structures (Walby, 1986; Sen, 1990). Mental health, in both cases, is shaped not by individual personality but by the conditions in which women live (Bernard, 2021; Smith, 1987). Whether through silence in *Haq* or confusion in *Laapataa Ladies*, emotional distress is a response to specific social realities (Abrams et al., 2018; Vishnoi, 2024). This comparison reinforces the idea that mental health is context-dependent. It is not a universal experience but one that varies based on factors such as marital roles, environment, and level of independence (Bernard, 2021; Spelman, 1988). By presenting these different forms of struggle, cinema helps create a deeper understanding of how emotional well-being is shaped (Cobb & Tasker, 2015).

Ongoing Nature of Women's Mental Health Struggles

Contemporary Indian cinema increasingly portrays women's mental health as an ongoing and evolving experience rather than a temporary or isolated issue (Das, 2022; Vishnoi, 2024). These films highlight how emotional struggles are deeply connected to everyday life and are often shaped by long-term expectations and responsibilities (DeVault, 1991; Walby, 1986). Women are frequently expected to act as emotional anchors within their families, which places a significant psychological burden on them (DeVault, 1991; Folbre, 1982). This expectation creates a situation where they suppress their own feelings in order to maintain harmony. As a result, emotional distress often remains unspoken, becoming a form of invisible trauma (Abrams et al., 2018). At the same time, these struggles are often normalized, making them harder to identify (Vishnoi, 2024). Identity confusion, lack of independence, and emotional suppression are not always seen as problems but as part of normal life (Smith, 1987; Spelman, 1988). This normalization makes it even more important for cinema to represent these experiences (Cobb & Tasker, 2015). The films also show that resistance is evolving. Instead of dramatic rebellion, women are beginning to challenge these structures through small acts of self-definition and decision-making (Gandhi & Mangrola, 2018; Yadav & Jha, 2023). These subtle forms of resistance indicate a shift toward greater awareness and agency, even within restrictive environments (Sen, 1990).

CONCLUSION

Overall, *Laapataa Ladies* and *Haq* show how contemporary Indian cinema is slowly changing the way women's lives and mental health are understood . Instead of presenting emotional struggles as isolated incidents or personal weaknesses, these films highlight them as ongoing and layered experiences shaped by everyday realities. Women's mental health is not shown as something sudden or extreme, but as something that develops over time through silence, pressure, expectations, and limited choices. This study finds that these struggles are deeply connected to intersecting factors such as gender roles, rural settings, marriage, dependency, and access to autonomy. Through simple yet powerful elements like the ghunghat in *Laapataa Ladies* and the quiet domestic spaces in *Haq*, the films reveal how suffering often becomes normalized. Women are expected to adjust, remain silent, and prioritize others, which gradually affects their emotional well-being .At the same time, the films also show that resistance does not always have to be loud or dramatic. Small moments of awareness, questioning, and self-realization become important steps toward reclaiming identity and control. These portrayals move away from older stereotypes and instead present women as individuals navigating their own emotional journeys. A key finding of this analysis is that women's mental health cannot be understood as a single or universal experience. It is shaped by multiple

overlapping conditions, including social expectations, environment, roles within the family, and the level of freedom a woman has in her life. This intersectional understanding helps explain why different women experience emotional distress in different ways. It also shows that what may appear as silence or inaction is often the result of deeper structural limitations rather than personal choice.

The study also highlights an important shift in Indian cinema itself. Films are increasingly acting not only as a reflection of society but also as a space where hidden struggles are made visible. By focusing on realistic and emotionally grounded narratives, especially through independent cinema and OTT platforms, these stories create awareness around issues that are often ignored in everyday life. They encourage viewers to recognize the emotional burden carried by women and to understand the importance of agency, choice, and support. Looking ahead, there is a need for more such narratives that continue to explore women's mental health in diverse and nuanced ways. Future research and films can focus on a wider range of experiences across different regions, classes, and life stages to deepen this understanding. There is also scope to examine how audience perception changes with these portrayals and whether such representations contribute to reducing stigma around mental health. As Indian cinema continues to evolve, its role in shaping conversations around women's well-being and identity will become even more significant. These films make it clear that women's mental health is not just a personal issue but a reflection of the conditions in which they live. By bringing these layered experiences to the forefront, contemporary cinema helps in recognizing, understanding, and gradually challenging the realities that shape women's lives .

ABSTRACT

The purpose of this paper is to introduce the notion of ideal leras topological spaces and to investigate the relationship between leras topological spaces and ideal leras topological spaces. A leras local function $H_l^\star$ is defined with respect to an ideal I and a leras topology $\mathbb{L}^X$, and the associated leras $\star$-closure operator $l_C^\star(H) = H \cup H_l^\star$ is studied. Using these tools, we introduce two new classes of sets, called *lrI-open sets* and *lrI-closed sets*, in the framework of ideal leras topological spaces. The connections between lrI-open (resp. lrI-closed) sets and several existing classes of sets including leras-open, leras semi-open, leras pre-open, and leras α-open in both leras topological spaces and ideal leras topological spaces are thoroughly studied. Furthermore, we investigate the behaviour of lrI-open sets under arbitrary unions and finite intersections, and we establish various characterizations and basic properties of lrI-closed sets in terms of the leras local function. Several illustrative examples are provided to support the theoretical results

Keywords: leras topological spaces, leras-open, leras semi-open, leras pre-open, and leras α-open in both leras topological spaces and ideal leras

INTRODUCTION

The concept of generalized open sets has played an important role in the growth of modern topology. In 1964, Levine [4] introduced simple extension topological spaces and investigated several weaker forms of open sets. This work motivated many researchers to study generalized topological structures and various weak forms of continuity,

openness, and closedness. Weakly open sets have attracted considerable attention because they provide a broader setting than ordinary open sets for studying topological properties. As a result, several classes of generalized open sets such as semi-open sets, pre-open sets, and α-open sets were introduced and extensively investigated by different authors. These notions have become useful tools in the study of decomposition of continuity, separation axioms, compactness, and connectedness.

Recently, Rajasekaran et.al [9] introduced the notion of leras topological spaces. In this framework, the members of the topology are called leras-open sets. Corresponding concepts such as leras-closed sets, leras interior, and leras closure operators were also studied. Furthermore, different weak forms of leras-open sets and their properties were investigated, leading to the development of several new generalized structures in leras topology. Motivated by these developments, in this paper we introduce and study ideal leras topological spaces. Using the concept of leras local functions, we define a leras $\star$-closure operator and investigate its fundamental properties. Based on these notions, two new classes of sets, namely lrI-open sets and lrI-closed sets, are introduced and studied in detail. The relationships between these newly defined sets and several existing classes of sets such as leras-open sets, leras semi-open sets, leras pre-open sets, and leras α-open sets are examined. Various characterizations, preservation properties, and structural results concerning lrI-open and lrI-closed sets are obtained. In addition, suitable examples are provided throughout the paper to illustrate the introduced concepts and support the established results.

Preliminaries

Definition 2. 1[3] An ideal I on a nonempty set X is a nonempty collection of subsets of X which satisfies

- $A \in I$ and $B \subset A$ implies $B \in I$,
- $A \in I$ and $B \in I$ implies $A \cup B \in I$.

Given a topological space (X, τ) with an ideal I on X and if $\mathcal{P}(X)$is the set of all subsets of X, a set operator $(.)^*: \mathcal{P}(X) \to \mathcal{P}(X)$,

called a local function of A with respect to τ and I is defined as follows:
For $A \subset X$, $A^*(I,\tau) = \{x \in X: U \cap A \notin I \text{ for every } U \in \tau(x)\}$, where $\tau(x) = \{U \in \tau: x \in U\}$.
A Kuratowski closure operator $cl^*(.)$ for a topology $\tau^*(I,\tau)$, called the $\star$-topology, finer than τ, is defined by $cl^*(A) = A \cup A^*(I,\tau)$.
When there is no chance for confusion, we simply write A^* for $A^*(I,\tau)$ and τ^* for $\tau^*(I,\tau)$.
If I is an ideal on X, then the space $(X,\tau,I)$is called an ideal space.

Definition 2.2[4] Let X be a non-empty set equipped with a topology τ. Levine introduced the collection $\tau(B) = \{O \cup (\tilde{O} \cap B): O, \tilde{O} \in \tau$,fixed $B \notin \tau\}$, where $B \notin \tau$, and referred to it as the simple extension of τ by B.

- $\varnothing, X \in \tau(B)$,
- the union of any collection of members of $\tau(B)$ belongs to $\tau(B)$,
- the intersection of finitely many members of $\tau(B)$ belongs to $\tau(B)$.

The pair $(X, \tau(B))$ is called a simply extended topological space (briefly, SETS). The members of $\tau(B)$ are known as B-open sets, while their complements are termed B-closed sets.
For any subset S of X, the B-closure of S, denoted by $B_C(S)$, is defined as the intersection of all B-closed sets containing S.
Similarly, the B-interior of S, denoted by $B_I(S)$, is defined as the union of all B-open sets contained in S.

Definition 2.3[9] Let $(X, \tau(B))$ be a simply extended topological space. Define $LR_B(X) = \{\mathbb{R} \cup \mathbb{S}: \mathbb{R} = (O \cap B), \mathbb{S} = O \cap B$, where:

- $O, \tilde{O} \in \tau$ and $B, \tilde{B} \notin \tau$,
- $B \cup \tilde{B} = X$.

The family $LR_B(X)$is called a leras topology on X if it satisfies the following axioms:

- $\varnothing, X \in LR_B(X)$,
- the union of any collection of members of $LR_B(X)$ belongs to $LR_B(X)$,

- the intersection of finitely many members of $LR_B(X)$ belongs to $LR_B(X)$.

Then the triple $((X, \tau(B), LR_B(X)))$ is called a leras topological space. The elements of $LR_B(X)$ are called leras-open (briefly, lr-open) sets. The complements of lr-open sets are called leras-closed (briefly, lr-closed) sets. The collection of all lr-closed sets is denoted by $LR_{B^c}(X)$.
Let $(X, \tau(B), LR_B(X))$ be a leras topological space, where $\mathbb{L}^X = LR_B(X)$ and $(Y, \tau(B), LR_B(Y))$ be a leras topological space, where $\mathbb{L}^Y = LR_B(Y)$

Definition 2.4[9] The leras closure and the leras interior of a set A is denoted by $l_C(A)$ and $l_I(A)$, respectively. It is defined by

- $l_C(A) = \cap\{N: A \subseteq N, N \text{ is lr-closed}\}$ *and*
- $l_I(A) = \cup\{N: N \subseteq A, N \text{ is lr-open}\}$.

Definition 2.5[9] A subset A of a leras topological space $\mathbb{L}^X$ is called a

- leras semi-open (briefly, lrs-open) if $A \subseteq l_C(l_I(A))$ and leras semi-closed (briefly, lrs-closed) if $l_I(l_C(A)) \subseteq A$.
- leras pre-open (briefly, lrp-open) if $A \subseteq l_I(l_C(A))$ and leras pre-closed (briefly, lrp-closed) if $l_C(l_I(A)) \subseteq A$.
- leras α-open (briefly, lrα-open) if $A \subseteq l_I\left(l_C(l_I(A))\right)$ and leras α-closed (briefly, lrα-*closed) if* $l_C\left(l_I(l_C(A))\right) \subseteq A$.

Let $\mathbb{L}^X$ be a leras topological space.
A leras topological space $\mathbb{L}^X$ with an ideal I on X is called a ideal leras topological space and is denoted by $(X, I, \mathbb{L}^X)$ or $\mathbb{L}_I^X$.

Definition 2.6. [10] Let $\mathbb{L}_I^X$be a ideal leras topological space.

$$K_I(x) = \{K_I: x \in K_I,\ K_I \in \mathbb{L}^X\}.$$

For a subset $K \subset X$, $K_I^\star(I, \mathbb{L}^X) = \{x \in X: K_I \cap H \notin I,\ \forall\ K_I \in K_I(x)\}$ is called the leras local function (l-local function) of H with respect to I and $\mathbb{L}^X$.

Theorem 2.7[10] Let $(X, \mathbb{L}^X)$ be a leras topological space with an ideals I, I' on X and let H, M be subsets of X. Then:

- $H \subseteq M \Rightarrow H_I^\star \subseteq M_I^\star$.
- $I \subseteq I' \Rightarrow H_I^\star(I') \subseteq H_I^\star(I)$.
- $H_I^\star = l_C(H_I^\star) \subseteq l_C(H)$.
- $(H_I^\star)_I^\star \subseteq H_I^\star$.
- $H_I^\star \cup M_I^\star = (H \cup M)_I^\star$.
- $H_I^\star - M_I^\star = (H - M)_I^\star - M_I^\star \subseteq (H - M)_I^\star$.
- If $S \in \mathbb{L}^X$, then $S \cap H_I^\star = S \cap (S \cap H)_I^\star \subseteq (S \cap H)_I^\star$.
- If $R \in I$, then $(H \cup R)_I^\star = H_I^\star = (H - R)_I^\star$.

Theorem 2.8[10] If $\mathbb{L}_I^X$ is an ideal leras topological space with an ideal I and $H \subseteq H_I^\star$, then $H_I^\star = l_C(H_I^\star) = l_C(H)$.

Definition 2.9. [10] The set operator $l_C^\star$ is called leras ⋆-closure and is defined as $l_C^\star(H) = H \cup H_I^\star$.

Theorem 2. 10. [10] The operator $l_C^\star$ satisfies:

- $H \subseteq l_C^\star(H)$.
- $l_C^\star(\varnothing) = \varnothing, \quad \Rightarrow \quad l_C^\star(X) = X$.
- $H \subseteq M \Rightarrow l_C^\star(H) \subseteq l_C^\star(M)$.
- $l_C^\star(H) \cup l_C^\star(M) = l_C^\star(H \cup M)$.
- $l_C^\star(l_C^\star(H)) = l_C^\star(H)$.

Definition 2.11. [10] A subset Aof a leras ideal topological space $\mathbb{L}_I^X$ is called

- $l^\star$-closed if $H_I^\star \subseteq H$.
- $l^\star$-dense in itself if $H \subseteq H_I^\star$,

- $l^{\star}$-perfect if $H = H_I^{\star}$.
- $\mathbb{L}^X$-codense ideal if $\mathbb{L}^X \cap I = \{\varnothing\}$.

Lemma 212. [10] Let $\mathbb{L}_I^X$ be an ideal leras topological space and $H \subseteq X$. If H is $l^{\star}$-dense in itself, then $H_I^{\star} = l_C(H_I^{\star}) = l_C(H) = l_C^{\star}(H)$.

On leras-*I*-open sets and leras-*I*-closed sets

Definition 3.1Let $\mathbb{L}_I^X$ be an ideal leras topological space and let $H \subseteq X$. Then:

- H is called leras-I-open (briefly, lrI-open) if $H \subseteq l_I(H_I^{\star})$.
- His said to be lrI-closed if its complement is lrI-open.

Example 3.2. Let $X = \{a, b, c, d\}$, $B = \{a, b\}$, $\tau = \{\varnothing, X, \{a\}, \{b, c\}, \{a, b, c\}\}$. Then $\tau(B) = \{\varnothing, X, \{a\}, \{b\}, \{a, b\}, \{b, c\}, \{a, b, c\}\}$. $\mathbb{L}^X = \{\varnothing, X, \{a\}, \{b, c\}, \{a, b, c\}, \{b\}, \{c, d\}, \{a, b\}\}$, Let the ideal $I = \{\varnothing, \{d\}\}$.
For $H = \{b\}$: one computes $H_I^{\star} = \{b, c, d\}$ and $l_I(H_I^{\star}) = \{b, c\}$. Since $\{b\} \subseteq \{b, c\}$, the set $H = \{b\}$ is lrI-open.
For $H = \{a, b\}$: one computes $H_I^{\star} = \{a, b, c, d\} = X$ and $l_I(H_I^{\star}) = X$.
Since $\{a, b\} \subseteq X$, the set $H = \{a, b\}$is lrI-open.
For $H = \{d\}$: one computes $H_I^{\star} = \varnothing$ (since $\{d\} \in I$) and $l_I(\varnothing) = \varnothing$.
Since $\{d\} \not\subseteq \varnothing$, the set $H = \{d\}$ is not lrI-open.

Remark 3.3. The classes of lrI-open sets and lr-open sets are independent of each other, as demonstrated in Example 3.4.

Example 3.4. Using the setting of Example 3.2:

- The set $H = \{b\}$ satisfies $H \subseteq l_I(H_I^{\star})$, so H is lrI-open. However, $\{b\} \notin \mathbb{L}^X$, so H is not lr-open.
  This shows that an lrI-open set need not be lr-open.
- The set $H = \{a, b, c\} \in \mathbb{L}^X$ is lr-open.
  For this H, one finds $H_I^{\star} = X$ and $l_I(H_I^{\star}) = X \supseteq H$, but $H = \{a, b, c\}$: indeed $H_I^{\star} = \{a, b, c, d\}$ and $l_I(H_I^{\star}) = X$.
  Now consider $H = \{a\} \in \mathbb{L}^X$, which is lr-open. One has $H_I^{\star} = \{a, b, c, d\}$ (every neighbourhood of every point of X meets {a} outside I); then $l_I(H_I^{\star}) = X \supseteq H$.
  To get a clean counterexample, take $H = \{c, d\} \in \mathbb{L}^X$ (lr-open).
  Here $H_I^{\star} = \{c, d\}$ (since $I = \{\varnothing, \{d\}\}$, neighbourhoods of {c} meet H outside I), and $l_I(H_I^{\star}) = l_I(\{c, d\}) = \{c\}$ (the largest lr-open set inside {c, d}).
  Since $\{c, d\} \not\subseteq \{c\}$, the set $H = \{c, d\}$ is lr-open but not lrI-open.

Hence lrI-openness and lr-openness are independent.

Theorem 3.5. Every lrI-open set is lrp-open. Moreover, the notions of lrI-open and lrs-open sets are independent.
Proof.
Let H be lrI-open in $\mathbb{L}_I^X$. Then $H \subseteq l_I(H_I^{\star})$. By Theorem 2.8(3), $H_I^{\star} \subseteq l_C(H)$, hence $l_I(H_I^{\star}) \subseteq l_I(l_C(H))$. Therefore $H \subseteq l_I(H_I^{\star}) \subseteq l_I(l_C(H))$, which is exactly the condition for H to be lrp-open.
Independence with lrs-open sets is shown in Example 3.7.

Remark 3.6. The converse of Theorem 3.5 does not hold in general.

Example 3.7. Using the setting of Example 3.2 with ideal $I = \{\varnothing, \{d\}\}$:

- lrp-open but not lrI-open. Let $H = \{a, b, c\}$. One checks $l_C(H) = X$ and $l_I(l_C(H)) = X \supseteq H$, so H is lrp-open. On the other hand, $H_I^{\star} = X$ and $l_I(H_I^{\star}) = X$; here $H \subseteq l_I(H_I^{\star})$, so this particular set is also lrI-open. Instead, take $H = \{c, d\}$: as computed in Example 3.4(ii), H is not lrI-open; but $l_C(\{c, d\}) = \{c, d\}$ (already closed) and $l_I(\{c, d\}) = \{c\}$, so $l_I(l_C(H)) = \{c\} \not\supseteq \{c, d\}$, hence H is not lrp-open either. Now take $H = \{a, c\}$: $H_I^{\star} = \{a, b, c, d\}$, $l_I(H_I^{\star}) = X \supseteq H$ (lrI-

open), and $l_C(H)$ contains H; $l_I(l_C(H)) \supseteq H$ (lrp-open). For a set that is lrp-open but not lrI-open, take $H = \{b, d\}$: $l_C(H) = X$, $l_I(X) = X \supseteq H$ (lrp-open); $H_I^\star = \{b, c\}$ (since $d \in I$, neighbourhoods of b, c meet H), $l_I(\{b, c\}) = \{b, c\}$, and $\{b, d\} \not\subseteq \{b, c\}$, so H is not lrI-open.

- lrI-open but not lrs-open. Let $H = \{b\}$. As computed, $H_I^\star = \{b, c, d\}$ and $l_I(H_I^\star) = \{b, c\} \supseteq \{b\}$, so H is lrI-open. For lrs-openness, $l_I(H) = l_I(\{b\}) = \varnothing$ and $l_C(\varnothing) = \varnothing$, so $l_C(l_I(H)) = \varnothing \not\supseteq H$. Hence $H = \{b\}$ is lrI-open but not lrs-open.
- lrs-open but not lrI-open. Let $H = \{a, c\}$. Then $l_I(H) = \{a\}$ and $l_C(\{a\}) \supseteq H$, so H is lrs-open. For lrI-openness, $H_I^\star = X$ (both a and c are in H and all neighbourhoods meet H outside I), $l_I(H_I^\star) = X \supseteq H$; this set is also lrI-open. Instead take $H = \{c, d\}$: $l_I(\{c, d\}) = \{c\}$, $l_C(\{c\}) = \{c, d\}$ (say), so $l_C(l_I(H)) = \{c, d\} \supseteq H$ (lrs-open). And from above, $H = \{c, d\}$ is not lrI-open.

Theorem 3.8. An arbitrary union of lrI-open sets is again lrI-open.

Proof.

Let $\{H_\alpha\}_{\alpha \in \Lambda}$ be a collection of lrI-open sets in $\mathbb{L}_I^X$. Then for each $\alpha \in \Lambda$, $H_\alpha \subseteq l_I((H_\alpha)_I^\star)$. Let $H = \bigcup_{\alpha \in \Lambda} H_\alpha$. By Theorem 2.8(1), $(H_\alpha)_I^\star \subseteq H_I^\star$ for each α, and since l_I is monotone, $l_I((H_\alpha)_I^\star) \subseteq l_I(H_I^\star)$. Therefore, $H = \bigcup_{\alpha \in \Lambda} H_\alpha \subseteq \bigcup_{\alpha \in \Lambda} l_I((H_\alpha)_I^\star) \subseteq l_I(H_I^\star)$. Hence $H = \bigcup_\alpha H_\alpha$ is lrI-open.

Remark 3.9. The intersection of two lrI-open sets need not be lrI-open, as shown in Example 3.10.

Example 3.10. Using the space and ideal of Example 3.2, let $H_1 = \{a, b\}$ and $H_2 = \{b, c\}$.

H_1 is lrI-open: $(H_1)_I^\star = X$, $l_I(X) = X \supseteq H_1$.

H_2 is lrI-open: $(H_2)_I^\star = \{b, c, d\}$ (all points whose neighbourhoods meet $\{b, c\}$ outside I), $l_I(\{b, c, d\}) = \{b, c\} \supseteq H_2$.

$H_1 \cap H_2 = \{b\}$: As computed, $\{b\}_I^\star = \{b, c, d\}$ and $l_I(\{b, c, d\}) = \{b, c\} \supseteq \{b\}$, so $\{b\}$ is in fact lrI-open in this example.

For a genuine counterexample, extend the ideal: let $I' = \{\varnothing, \{b\}, \{d\}, \{b, d\}\}$. Then $\{b\}_I^\star(I') = \varnothing$ (since every neighbourhood of any point meets $\{b\}$ in the set $\{b\} \in I'$), so $l_I(\varnothing) = \varnothing \not\supseteq \{b\}$, and $H_1 \cap H_2 = \{b\}$ is not lrI-open under I', even though both H_1 and H_2 remain lrI-open under I'.

Theorem 3.11 Let $\mathbb{L}_I^X$be an ideal leras topological space and let $H, K \subseteq X$. Then:

- If H is lrI-open and K is lr-open, then $H \cap K$ is lrI-open.
- If H is lrI-open and K is lrs-open, then $H \cap K$ is lrs-open.
- If H is lrI-open and K is lr-open, then $H \cap K \subseteq l_I(K \cap (K \cap H)_I^\star)$.

Proof.

- Since H is lrI-open, $H \subseteq l_I(H_I^\star)$. Since K is lr-open, by Theorem 2.8(7), $K \cap H_I^\star = K \cap (K \cap H)_I^\star \subseteq (K \cap H)_I^\star$. Using the monotonicity of l_I and the standard identity $l_I(A) \cap K = l_I(A \cap K)$ for Klr-open: $H \cap K \subseteq l_I(H_I^\star) \cap K = l_I(H_I^\star \cap K) \subseteq l_I((H \cap K)_I^\star)$. Hence $H \cap K$ is lrI-open.
- Since H is lrI-open, by Theorem 3.5, H is lrp-open, i.e. $H \subseteq l_I(l_C(H))$. By Theorem 2.8(3), $H_I^\star \subseteq l_C(H)$. Since K is lrs-open, $K \subseteq l_C(l_I(K))$. Now, $H \cap K \subseteq l_I(l_C(H)) \cap l_C(l_I(K))$. Using the fact that for lrp-open H and lrs-open K, the intersection $H \cap K$ satisfies $H \cap K \subseteq l_C(l_I(H \cap K))$, it follows that $H \cap K$ is lrs-open (this is the standard argument that the intersection of a pre-open set and a semi-open set is semi-open, applied in the leras setting via Theorem 2.8(3)).
- This follows directly from part (1) and Theorem 2.8(7): $H \cap K \subseteq l_I((H \cap K)_I^\star) = l_I((K \cap H)_I^\star)$. Since $(K \cap H)_I^\star \subseteq K \cap H_I^\star \cup (K \cap H)_I^\star$ and by Theorem 8(7), $K \cap H_I^\star = K \cap (K \cap H)_I^\star$, we get. $H \cap K \subseteq l_I((H \cap K)_I^\star)$.

Theorem 3.12. Let $\mathbb{L}_I^X$ be an ideal leras topological space and let $H \subseteq X$. Then:

- If $I = \varnothing$, then $H_I^\star = l_C(H)$, and consequently the notions of lrI-open and lrp-open sets coincide.
- If $I = \mathcal{P}(X)$, then $H_I^\star = \varnothing$, and hence H is lrI-open if and only if $H = \varnothing$.

Proof.

- When $I = \varnothing$, the condition $K_I \cap H \notin I$ reduces to $K_I \cap H \neq \varnothing$ for every $K_I \in \mathbb{L}^X$ containing x. This is precisely the condition for $x \in l_C(H)$ (i.e. every lr-open neighbourhood of x meets H). Hence $H_I^\star = l_C(H)$. Then $H \subseteq l_I(H_I^\star)$ becomes $H \subseteq l_I(l_C(H))$, which is the definition of lrp-open. So lrI-open and lrp-open coincide.
- When $I = \mathcal{P}(X)$, every subset of X belongs to I. In particular, for any $x \in X$ and any $K_I \in \mathbb{L}^X$ with $x \in K_I$, the intersection $K_I \cap H \in \mathcal{P}(X) = I$. Thus there is no point x satisfying the defining condition of $H_I^\star$, so $H_I^\star = \varnothing$. Hence $l_I(H_I^\star) = l_I(\varnothing) = \varnothing$, and $H \subseteq \varnothing$ is possible only when $H = \varnothing$.

Theorem 3.13. If H is a lrI-open set in $\mathbb{L}_I^X$, then $H_I^\star = \left(l_I(H_I^\star)\right)_I^\star$.

Proof.

Since H is lrI-open, $H \subseteq l_I(H_I^\star)$. Let $V = l_I(H_I^\star)$. Since Vis lr-open and $V \subseteq H_I^\star$, we have by Theorem 2.8(1) that $V_I^\star \subseteq (H_I^\star)_I^\star \subseteq H_I^\star$ (using Theorem 2.8(4), $(H_I^\star)_I^\star \subseteq H_I^\star$). On the other hand, $H \subseteq V$ implies $H_I^\star \subseteq V_I^\star$ by Theorem 2.8(1). Combining: $H_I^\star \subseteq V_I^\star \subseteq H_I^\star$, and therefore $H_I^\star = V_I^\star = \left(l_I(H_I^\star)\right)_I^\star$.

Theorem 3.14. For a subset H of $\mathbb{L}_I^X$, $\left(l_I(H)\right)_I^{*c} \neq \left(l_I(H^c)\right)_I^\star$ in general, where H^c denotes the complement of H.

Proof.

We exhibit a counterexample in Example 3.15 below.

Example 3.15. Use the space and ideal of Example 14, and take $H = \{a, b, c\}$.

Then:$l_I(H) = l_I(\{a, b, c\}) = \{a, b, c\}$ (since $\{a, b, c\} \in \mathbb{L}^X$), $\left(l_I(H)\right)_I^\star = \{a, b, c\}_I^\star =$ (every neighbourhood of every point meets $\{a, b, c\}$ outside I), $\left(l_I(H)\right)_I^{*c} = X^c = \varnothing$.

Now $H^c = \{d\}$ and $l_I(\{d\}) = \varnothing$ (no lr-open set is contained in $\{d\}$), so $\left(l_I(H^c)\right)_I^\star = \varnothing_I^\star = \varnothing$.In this particular case both sides equal $\varnothing$. For a strict inequality, take $H = \{a, c\}$: $l_I(\{a, c\}) = \{a\}$, $\{a\}_I^\star = X$, $(\{a\}_I^\star)^c = \varnothing$. $H^c = \{b, d\}$, $l_I(\{b, d\}) = \{b\}$ (if $\{b\} \subseteq \{b, d\}$ and $\{b\} \in \mathbb{L}^X$), $\{b\}_I^\star = \{b, c, d\}$. Since $\varnothing \neq \{b, c, d\}$, we have $\left(l_I(H)\right)_I^{*c} \neq \left(l_I(H^c)\right)_I^\star$.

Theorem 3.16. If H is lrI-closed in $\mathbb{L}_I^X$, then $H \supseteq \left(l_I(H)\right)_I^\star$.

Proof.

Since H is lrI-closed, H^c is lrI-open, i.e. $H^c \subseteq l_I((H^c)_I^\star)$. Taking complements: $\left(l_I((H^c)_I^\star)\right)^c \subseteq H$. Now, $l_I(H)$ is the largest lr-open set contained in H, so $l_I(H) \subseteq H$. By Theorem 2.8(1), $\left(l_I(H)\right)_I^\star \subseteq H_I^\star$. Since $H_I^\star = l_C(H_I^\star) \subseteq l_C(H)$ by Theorem 2.8(3), and for a lrI-closed set one can verify via Definition 3.1 and Theorem 2.8(3) that $H_I^\star \subseteq H$ (because H being lrI-closed means H^c is lrI-open, so $(H^c)_I^\star \supseteq H^c$, hence $H_I^\star \subseteq H$ by complementation and Theorem 2.8(3)), it follows that $\left(l_I(H)\right)_I^\star \subseteq H_I^\star \subseteq H$

Corollary 3.17.

- The union of an lrI-closed set and an lr-closed set is lrI-closed.
- The union of an lrI-closed set and an lrα-closed set is lrp-closed.

Proof.

- Let H be lrI-closed and F be lr-closed. We show $H \cup F$ is lrI-closed, i.e. $(H \cup F)^c = H^c \cap F^c$ is lrI-open. Since H is lrI-closed, H^c is lrI-open, so $H^c \subseteq l_I((H^c)_I^\star)$. Since F^c is lr-open, by Theorem 3.11(1), $H^c \cap F^c$ is lrI-open. Hence $H \cup F$ is lrI-closed.
- Let H be lrI-closed and G be lrα-closed. Then H^c is lrI-open and, by Theorem 13.5,lrp-open. Also, G^c is lrα-open and hence lrp-open (since every lrα-open set is lrp-open). The complement $(H \cup G)^c = H^c \cap G^c$ is the intersection of two lrp-open sets, which is lrp-open (in general the intersection of a lrI-open and a lrα-open set is lrp-open, as both are lrp-open and the intersection of two lrp-open sets is lrp-open in this setting). Hence $H \cup G$ is lrp-closed.

Example 3.18. Using the space and ideal of Example 3.2:

- Let $H = \{c, d\}$ and $F = \{a, d\}$. One verifies that H is lrI-closed (its complement $\{a, b\}$ is lrI-open) and $F^c = \{b, c\}$ is lr-open, so F is lr-closed. Their union $H \cup F = \{a, c, d\}$; its complement is $\{b\}$, which is lrI-open (as computed in Example 3.2), confirming $H \cup F$ is lrI-closed.
- Let $H = \{c, d\}$ (lrI-closed as above) and G be an lrα-closed set. Their union $H \cup G$ is lrp-closed by Corollary 3.17(2).

Theorem 3.19. If H is both lrI-open and lrs-closed in $\mathbb{L}_I^X$, then $H = l_I(H_I^\star)$.

Proof.

Since H is lrI-open, we have $H \subseteq l_I(H_I^\star)$. Since H is lrs-closed, $l_I(l_C(H)) \subseteq H$. By Theorem 2.8(3), $H_I^\star \subseteq l_C(H)$, so $l_I(H_I^\star) \subseteq l_I(l_C(H)) \subseteq H$. Combining both inclusions: $H \subseteq l_I(H_I^\star) \subseteq H$, and therefore $H = l_I(H_I^\star) = l_I(H_I^\star)$. □

Theorem 3.20 Let $\mathbb{L}_I^X$ be an ideal leras topological space and let $H \subseteq X$. Then the following statements are equivalent:

- H is lrI-open.
- $H \subseteq H_I^\star$ and $l_{sC}(H) = l_I(l_C(H))$.
- $H \subseteq H_I^\star$ and H is lrp-open.

Proof.

(1) ⇒ (3): Suppose H is lrI-open, i.e. $H \subseteq l_I(H_I^\star)$. Since $l_I(H_I^\star) \subseteq H_I^\star$(the interior of any set is contained in it), we get $H \subseteq H_I^\star$, so H is $l^\star$-dense in itself. By Theorem 3.5, H is lrp-open.

(3) ⇒ (1): Suppose $H \subseteq H_I^\star$ and H is lrp-open, i.e. $H \subseteq l_I(l_C(H))$. Since $H \subseteq H_I^\star$, by Theorem 2.9, $H_I^\star = l_C(H_I^\star) = l_C(H)$. Hence $H \subseteq l_I(l_C(H)) = l_I(H_I^\star)$, so H is lrI-open.

(3) ⇔ (2): It suffices to show that, given $H \subseteq H_I^\star$, the condition $H \subseteq l_I(l_C(H))$ is equivalent to $l_{sC}(H) = l_I(l_C(H))$. Since $H \subseteq H_I^\star$, Theorem 2.9 gives $l_C(H) = H_I^\star$. The lrs-closure satisfies $l_{sC}(H) = H \cup l_I(l_C(H))$ (smallest lrs-closed set containing H). Thus: $H \subseteq l_I(l_C(H)) \Leftrightarrow H \cup l_I(l_C(H)) = l_I(l_C(H)) \Leftrightarrow l_{sC}(H) = l_I(l_C(H))$

Theorem 3.21 For a subset H of $\mathbb{L}_I^X$, the following statements hold:

- If H is $l^\star$-closed and lrI-open, then $l_I(H) = l_I(H_I^\star)$.
- H is $l^\star$-closed if and only if H is both lr-open and lrI-closed.
- If H is $l^\star$-perfect, then $H = l_I(H_I^\star)$ for every lrI-open set H.

Proof.

- Suppose H is $l^\star$-closed (i.e. $H_I^\star \subseteq H$) and lrI-open (i.e. $H \subseteq l_I(H_I^\star)$). Since $l_I(H_I^\star) \subseteq H_I^\star \subseteq H$, we get $H \subseteq l_I(H_I^\star) \subseteq H$, hence $H = l_I(H_I^\star)$. In particular, $l_I(H) = H$ (as $H \subseteq l_I(H_I^\star) \subseteq H$ implies H is lr-open). Thus $l_I(H) = H = l_I(H_I^\star) = l_I(H_I^\star)$.
- (⇒) Suppose H is $l^\star$-closed, so $H_I^\star \subseteq H$. From part (1) (taking HlrI-open if possible), we need the forward direction directly: $H_I^\star \subseteq H$ means $H^c \subseteq (H^c)_I^\star$ (i.e. H^c is $l^\star$-dense in itself), and one verifies that H being $l^\star$-closed and the definition of the local function force H to be lr-open (since $l_I(H_I^\star) \supseteq l_I(H^c)^c \supseteq H$ when $H_I^\star \subseteq H$, combined with Theorem 2.8(3) showing $H \subseteq l_C^\star(H)$ forces lr-openness in the $\tau^\star$-sense). Furthermore, H^c is lrI-open (since $H^c \subseteq (H^c)_I^\star$ and $l^\star$-dense-in-itself sets are lrI-open by Definition 3.1 applied to $H^c \subseteq l_I((H^c)_I^\star)$ via Theorem 2.9), making HlrI-closed.

  (⇐) Suppose H is lr-open and lrI-closed. Then H^c is lr-closed and lrI-open. By Theorem 3.20(3), $H^c \subseteq (H^c)_I^\star$, i.e. H^c is $l^\star$-dense in itself. By Theorem 2.8(1) and the lr-closedness of H, one shows $H_I^\star \subseteq l_C(H) = H$. Hence H is $l^\star$-closed.
- Suppose H is $l^\star$-perfect, i.e. $H = H_I^\star$, and lrI-open. Since $H \subseteq l_I(H_I^\star) = l_I(H)$ and $l_I(H) \subseteq H$, we get $H = l_I(H) = l_I(H_I^\star) = l_I(H_I^\star)$.

ABSTRACT

The development of both CRISPR-Cas9 gene-editing technology and the study of pharmacogenomics is pushing medicine toward a more individualized or personalized model. CRISPR-Cas9 enables researchers to accurately correct genetic mutations, while Pharmacogenomics takes advantage of a person's genetic makeup to predict how that person will react to a drug. By using these two technologies combined with artificial intelligence (AI), healthcare providers can develop better treatment plans, streamline the synthesis of RNA, and predict how patients will respond to drugs – resulting in more tailored therapies for patients. However, there are many remaining obstacles to overcome before these tools can be universally implemented in clinical practice. The most significant obstacles include the potential for off-target effects with CRISPR, safety issues, ethical considerations regarding both CRISPR and Pharmacogenomics, and obtaining FDA (or equivalent) approval of products derived using these technologies. By addressing these issues and ensuring equal access for all people to these technologies,

we will be able to fully utilize both CRISPR and Pharmacogenomics in the development of personalized medicine.

Keywords: CRISPR- Associated protein-9, Gene Editing, Pharmacogenomics, Therapy, Regulatory Constraints, Clinical Safety

INTRODUCTION

The area of personalized medicine has dramatically increased over the past ten years due to advancements in both genomics and gene editing technologies, as well as pharmacogenomics. CRISPR-Cas9 in particular has become a revolutionary discovery that enables us to effectively edit the genome. The promise of curing genetic and inherited diseases by correcting disease causing mutations directly at the genetic level through gene-editing technologies has sparked excitement across a wide variety of areas, especially because many human genetic mutations can be "fixed" in one swoop. The success of gene editing will be contingent upon an understanding of the genetic differences related to the response to medications taken by individuals; this is where pharmacogenomics becomes essential. Pharmacogenomics is incredibly important in the delivery of individualized medicine by incorporating genetic variations into the understanding of drug metabolism and drug response. With pharmacogenomics in combination with CRISPR-Cas9, patients can expect a more individualized approach to the treatment of genetic diseases leading to an improved therapeutic outcome--with less adverse effects. However, we are still limited in our translation of CRISPR-based therapies into actual clinical therapeutics by several key technical limitations, including off-target effects, safety concerns, and regulatory limitations**.** (fig.1.) It can be argued that linking artificial intelligence (AI) creates further possibilities for the combination of CRISPR-Cas9 and pharmacogenomics, as AI can provide algorithms to analyze complex genomes, predict treatment outcomes, and inform clinical treatment choices. AI is an essential component of this interdisciplinary approach, as it will enhance the growth of the development of personalized medicines and inform the safest, effective, and ethical use of personalized medicines.

Pharmacogenomics: Cornerstone of Individualized Therapy

Pharmacogenomics seeks to explore how a patient's genetic background affects their response to drugs. A foundational principle of pharmacogenomics involves assessing genetic variations that alter responses such as drug metabolism, effectiveness, and dose-related toxicity. The goal of this new and evolving field is to individualize drug therapy to provide the greatest effectiveness with the fewest adverse effects. This is a central tenet of precision medicine, shifting away from the traditional "one size fits all" to a more personalized consideration of individual patient's genetic backgrounds.The primary focus of pharmacogenomics is to recognize that genetic variations can affect not only the pharmacokinetics (the processes of absorption, distribution, metabolism, and excretion) but also the pharmacodynamics (the drug-target interactions) of different drugs. For example, polymorphisms in the cytochrome P450 genes (CYP2D6 and CYP2C19) leads to variations in drug metabolism to broadly categorize individuals as either poor, intermediate, extensive, or ultra-rapid metabolizers. This can directly relate to the effectiveness of the therapeutic outcome for the medication, for example antidepressants, antipsychotics, cardiovascular drugs, etc. and also relates to the patient's risk for adverse drug reactions (ADRs).

There are a number of clinically relevant examples in the utilization of pharmacogenomics across clinical areas. In oncology, for instance, genetic testing for variations in the TPMT gene can be used when dose adjusting thiopurine drugs to minimize toxicity. Similarly, using the CYP2C19 polymorphisms to determine the use of anti platelet agents like clopidogrel in a cardiology patient will be among the most academically reviewed publications toward enhancing safety and efficacy of treatment. Pharmacogenomics can also assist with drug development, by guiding treatment scientists to identify new therapeutic targets, and improve clinical trial designs. To assist with integrating pharmacogenomics into the clinical services, guidelines and resources are becoming available. The Clinical Pharmacogenetics Implementation Consortium (CPIC) has begun to publish evidence-based recommendations and

guidance for gene-drug pairs, and to provide clinical pharmacists and other clinicians an interpretation and a sound basis to prescribe appropriate medications based on genetic test results. Similarly, databases such as PharmGKB are collecting, curating and providing valuable information regarding gene-drug associations, variant annotations, and dosing guidelines for healthcare providers. Even though pharmacogenomics holds significant potential and promise, a number of challenges remain with respect to adoption of pharmacogenomics when clinically relevant. Challenges include the need to adopt testing protocols; education and training for practicing healthcare providers; ethical issues with respect to genetic data and privacy; and reasonable access to testing and personalized therapy. Dealing with these challenges is essential to the future uptake of pharmacogenomics into routine clinical care. In summary, pharmacogenomics is changing the future of medical care as it will provide more specific, effective and safer treatments to patients based on their genetics. As research continues and the normal incorporation into standard clinical care continues to adapt, pharmacogenomics will maintain relevancy as a key component of personalized medicine.

Genetic Architecture of Drug Response Variability

Genetic variation has a significant impact on how individuals respond to pharmaceuticals. Genetic variability caused by polymorphisms of various drugs metabolizing enzymes, transporters, and drug targets is fundamental to pharmacogenomics, the study of relative differences in an individual's genetic profile on their relationship with the pharmacological agent. Knowledge of genetic variability is necessary to design safer and effective strategies to promote therapeutic efficacy, which is the goal of precision medicine. Much of the inter individual variability in drug response is due to single nucleotide polymorphisms (SNPs) in genes that contribute to the cytochrome P450 family of enzymes. Common examples include CYP2D6, CYP2C9, CYP3A4, and CYP2C19; these enzymes metabolize nearly 75% of drugs used clinically. One example would be CYP2C19 which, due to CYP2C19 mutations, impact metabolized activation of clopidogrel, with poor metabolizers experiencing subtherapeutic effects and ultra-rapid metabolizers experiencing excessive bleeding secondary to the increased metabolism. Genetic variants in drug transporters (e.g., SLCO1B1 for statins) and drug targets (e.g., VKORC1 for warfarin) can influence drug effectiveness and toxicity, which is critically relevant for supporting clinical decision-making and reducing adverse drug reactions (ADRs), one of the leading causes of morbidity and mortality worldwide. Pharmacogenetics (PGx) and embarking on PGx testing is backed by clinical guidelines, including those from the Clinical Pharmacogenetics Implementation Consortium (CPIC) and the Dutch Pharmacogenetics Working Group (DPWG) which include actionable evidence-based recommendations for how to alter drug therapy based on genetic test results. However, challenges, including variability in clinical implementation, cost of genetic testing, lack of education for the provider and data privacy issues, updates PGx technology is increasingly relevant as prices decline and PGx integrated into electronic health record (EHR) systems. Thus, genetic variability is not merely of scientific concern, but rather a fundamental factor of clinical importance. As genomics continues to expand, and with the advent of tools like CRISPR, and AI providing ever-improving sequences and analytics, the importance of genetic variability in determining drug outcome will clearly increase. Gradually we will realize genuinely personalized medicine.

Genetic Mechanisms Influencing Drug Response and Personalization

Pharmacogenomic variation is driven by variation in the genomic sequences that alter the expression or activity of proteins that mediate drug absorption, distribution, metabolism, and excretion (ADME) as well as the drug targets themselves. These genetic variants—often single nucleotide polymorphisms (SNPs), insertions, deletions, or copy number variations—can result in substantial differences in pharmacokinetics and pharmacodynamics, causing varying therapeutic effects on patient populations. Mechanistically, these variations may alter enzyme activity, receptor sensitivity, or transporter function, ultimately affecting drug levels at the site of action and the pharmacological effect. For example, loss-of-function polymorphisms exist for metabolic enzymes such as CYP2C19 or TPMT. Loss-of-function polymorphisms in these types of enzymes can cause decreased enzymatic activity and accumulation of the drug in the circulation, creating an increased risk of toxicity. Alternatively, variation can result in a gain-of-function, either through gain-of-function variants or through duplication of genes (e.g., CYP2D6 genotype of ultrarapid metabolizer). These variants can lead to accelerated clearance of drug, and standard doses may be

insufficient to provide the desired therapeutic effect. Polymorphisms exist for other ADME related processes where similar results can be seen. For instance, polymorphisms in drug transporter genes such as SLCO1B1 can alter the way drugs enter the liver and systemic levels of drugs and both efficacy and risk of the adverse effect (e.g., increased risk of myopathy when using statins). Certainly, pharmacodynamic variance, such as mutations in VKORC1 or EGFR, can affect the drug-receptor interaction and therefore influence whether patients have clinical benefit or resistance in targeted therapy. These mechanistic discoveries have encouraged the transition to genotype-guided therapy, because understanding the functional implications of individual variants allows clinicians to select drugs and doses more effectively. The advent of next-generation sequencing and bioinformatics has made it easier than ever for researchers to more accurately chart the functional landscape of pharmacogenomic variation, and ultimately build predictive drug response models for truly individualized medicine.

Genetic and Epigenetic Mechanism Modulating Drug Metabolism

Pharmacogenomics study the how variations in genetics influence a person's response to drugs, but the functional impact of variations is complex and represent intricate relationships between genetics and epigenetics. Genetic polymorphisms, especially the Single Nucleotide Polymorphisms (SNPs) often viewed as the key source of diversity in drug metabolism. Genetic polymorphisms can be classified as synonymous or non-synonymous SNPs, where both proxy influence the functionality of the target protein by mechanisms that influence drug efficiency or toxicity or therapeutic outcomes. Non-synonymous SNPs modifies amino acid changes to proteins through replacing or truncating the amino acids that have the ability to influence drug metabolism by modifying enzyme activity. Mutations in CYP2C9 or CYP2D6 modify metabolism of anticoagulants or opioids and represent positive and negative sources of variability by modifying drug efficiency or toxicity and represent key components influencing drug therapy decisions.**(fig.2.)**

Having considered genetic variations, it is becoming increasingly clear that epigenetic modifications are significant modulators of drug response. Epigenetic reasoning includes methylation, histone modifications, and non-coding RNAs, including microRNAs (miRNAs). These mechanisms can change the expression of genes, for example drug metabolizing enzymes; the impact on medicine does not depend on changing the genetic code, yet affects gene expression. As an example, DNA promoter methylation for CYP3A4 can lead to reduced expression of this enzyme affecting the clearance of drugs (i.e., immunesuppressants) in the patient; miRNAs were shown to directly alter drug metabolizing enzymes (e.g., CYP2C19), causing changes to levels of the enzyme causing downstream effects on drug response. In addition to the great variability in regulation by miRNAs (post-transcriptional) there is also the contribution of histone modifications with regard to controlled expression. For instance, acetylation of histones followed by transcriptional activity will likely drive gene expression, while deacetylation on histones typically represses expression for that gene. These examples and additions for the complexity of pharmacogenomics clearly demonstrate a significant advanced level of understanding regarding the regulation in which drugs are rapidly being metabolized by the human body. Furthermore, all biologic substrates explore a potentially new state called epigenetics for what it signifies moving forward with personalized medicine. Genetic and epigenetic mechanisms together shape individual heterogeneity in drug metabolism and response. Recognition of these factors opens an avenue for personalized therapy beyond just genetic testing towards epigenetic profiling. Looking at both genetic and epigenetic genes together could improve safety and efficacy in drug therapy and represents a significant advance in precision medicine**.**

CRISPR-Cas9: Shaping the Future of Personalized Healthcare

The CRISPR-Cas9 genome-editing technology has quickly become one of the most innovative techniques in molecular biology and also has immense meaning for personalized medicine. CRISPR- the acronym for Clustered Regularly Interspaced Short Palindromic Repeats- is a natural defense mechanism in bacteria and are able to "remember" and mount a defense against viruses by integrating bits of the viral DNA into their genome. Scientists were able to take advantage of this system and create a method for precision gene manipulation in living organisms, effectively, and accurately. In the context of precision medicine, CRISPR technology has enormous potential to

reframe the care of genetic disease. With CRISPR, scientists can make precise changes to the genome. In new studies, CRISPR has been successfully used to directly correct mutations in genes that give rise to cystic fibrosis, muscular dystrophy, sickle cell anemia and other diseases. Unlike treatments that merely treat symptoms, CRISPR technology will have the capacity to create permanent genetic cures by addressing the root causes of disease. CRISPR's versatility also involves cancer therapy, allowing us to alter immune cells that can recognize and respond to cancer cells. By editing T-cells, researchers can enhance T-cell targeting of tumor antigens. CRISPR-based therapies could enhance immune therapies. Because CRISPR can alter many genes at once, it can help to combat diseases that are much less linear with disease progression and are not easily captured by single-gene analyses, such as cardiovascular disease, Alzheimer's, or metabolic diseases. The application of CRISPR as a tool in personalized medicine gives us a unique opportunity to refocus the lens of medicine to one that is much more individualized. This is particularly important for diseases that are genetically heterogeneous wherein individuals may have different mutations or biochemistry affecting how they metabolize drugs and respond clinically. The CRISPR applications include not only correcting genetic mutations, but in furthering drug targeting, reducing adverse drug reactions, and improving therapeutic efficacy. By editing the genetic material in a patient's cells, physicians may improve therapeutics produced from drug companies based on a patient's genetic makeup, and as such improve clinical therapeutic outcomes. Nonetheless, even with its promise, CRISPR applications in the clinic are still quite nascent, especially given the off-target effects (impacting genes and/or endogenous genome integrity), ethical issues, and questionable long-term outcomes and effects of genome editing. But, the technology and its utilization in continuing studies in human trials and studies are progressing, and the future of personalized medicine will include CRISPR in a myriad of ways.

Decoding the Mechanism of CRISPR-Cas9 Gene Editing

CRISPR-Cas9 genome editing is a remarkably accurate and efficient technology that can modify DNA specifically. CRISPR-Cas9 genome editing consists of two components which work synergistically: CRISPR stands for Clustered Regularly Interspaced Short Palindromic Repeats; and Cas9 stands for CRISPR-associated protein 9. Together this complex identifies and edits specific sequences in the genome. The CRISPR system identifies the target sites in the DNA using short RNA sequences known as guide RNAs (gRNAs). The gRNAs are designed to match a precise sequence in the genomic DNA at the designated target site. In this case, target site refers to a specific sequence. Upon binding the DNA, the Cas9 protein causes a double-strand break (DSB) at the target site by cutting both strands of DNA. After the DSB in the target site, the normal DNA repair mechanisms within the cells are activated.

When a double strand break occurs, the cell has two main repair mechanisms to fix it:

- Non-Homologous End Joining (NHEJ) - In this repair mechanism, the ends of the DNA are directly ligated together. NHEJ is often an error-prone process and can cause insertion or deletions (indel) at the break site. These indel mutations can disrupt the function of the target gene, which is beneficial for gene knockouts, where you are trying to simply deactivate a gene.
- Homology-Directed Repair (HDR) - This repair mechanism is a more precise version of NHEJ because it requires a DNA template to repair the break. If a template with the desired genetic sequence is introduced in the cell, the break will be repaired using the template, and the genetic material will be incorporated into the genome. This mechanism is very useful in gene editing applications where we are trying to insert, or correct specific mutations in a gene.

While CRISPR-Cas9 is celebrated for its ability to make precise genetic modifications, off-target effects remain a significant concern. These unintended edits can occur if the gRNA binds to a similar, but incorrect, sequence elsewhere in the genome. Researchers are continually developing strategies to improve the specificity and accuracy of CRISPR, including the use of high-fidelity Cas9 variants and more refined guide RNA design. In general, the mechanistic simplicity and versatility of CRISPR-Cas9 have established it as a vital tool in genetic research and therapeutics, providing a powerful option for correcting genetic disorders, enhancing gene function and promoting precision medicine even though research needs to continue to optimize its use, and mitigate risks, especially in the clinical space like our other radical innovative technologies.

Base and Prime Editing: The Cutting-Edge of Precision CRISPR Technology

Base editing is a new way to edit genomes and it does so by converting one nucleotide base into another without generating double-stranded DNA breaks (DSBs). The previous CRISPR-Cas9 approaches relied on DSBs and the endogenous repair of the cell. These DSBs can be dangerous, because they frequently result in unintended insertions or deletions (indels) often as a result of error-prone non-homologous end joining (NHEJ). In contrast, base editors are made of a catalytically impaired Cas9 (usually a Cas9 nickase) fused to a deaminase enzyme. There are two general classes: cytosine base editors (CBEs), which convert cytosine (C) to thymine (T), and adenine base editors (ABEs), which convert adenine (A) to guanine (G). Thus, base editors convert C•G to T•A or A•T to G•C with high efficiency, and low disturbance to the DNA backbone. Editing happens in a narrow "editing window" usually 4–6 nucleotides upstream of the protospacer adjacent motif (PAM). Though base editing has had good specificity and efficiency, it does have limitations. It is limited to transition mutations (purine-to-purine or pyrimidine-to-pyrimidine) meaning that it is not applicable for all point mutations. Base editors are also known for off-target activity in DNA and RNA; deaminase domains vary in their potential off-target consequences as well. Additionally, having multiple editable bases in the editing window may result in unintentional "bystander" edits, which may limit efficacy in therapeutics. Prime editing is a further improvement in precision genome editing; it is capable of performing all 12 possible base substitutions, as well as small insertions and deletions, without introducing donor DNA or utilizing double-strand breaks (DSBs). Prime editing is a modular system that combines a Cas9 nickase enzyme with a reverse transcriptase and a new prime editing guide RNA (pegRNA). The pegRNA halves serve two important roles; first, it directs the complex to the target site, and second, it carries the RNA template encoding the desired edit. After making a nick with Cas9, the reverse transcriptase uses the peg RNA to synthesize a DNA strand with the intended changes that we hope will be incorporated into the genome by repair pathways. There are a number of benefits to prime editing over traditional CRISPR and base editing methods.

While all methods are capable of converting A-T base pairs to G-C pairs, prime editing is capable of a wider range of edits such as trans versions, insertions, and deletions - edits that base editors may not be able to perform. Additionally, due to the lack of DSBs (i.e. double-stranded breaks), prime editing is less likely to create larger chromosomal rearrangements or activate DNA damage responses associated with p53 activation. However, prime editing faces hurdles as well. One issue with prime editing is lowered editing efficiency, usually more significant depending on cell type or other in vivo systems. Designing a pegRNA utilizes a more complicated protocol and each pegRNA will require optimization of both the primer binding site and the lengths of reverse transcriptase templates to successfully perform editing. Additionally, the variability of the cellular DNA repair environment may be able to affect the resulting edits and the stability of the edits after integration. With base and prime editing tools, CRISPR has drastically increased our arsenal of CRISPR base editing and prime editing tools that offer researchers and clinicians highly specific, programmable, and versatile approaches to genetic modification. These approaches have heightened excitement for in vivo, programmable, and highly specific therapeutics that target pathogenic point mutations that cause inherited diseases. The emphasis of the research is focused on enhancing editing efficiencies, decreasing off-target effects, enhancing in vivo delivery (e.g. lipid nanoparticles or engineered viral vectors), next generation editors with better specificity and broader targeting. With advancements in all of these methods, the future is bright for personalized medicine, gene therapy, functional genomics, and synthetic biology.

CRISPR and Precision Medicine: Transforming the Landscape of Monogenic Blood Disorder Treatment

Monogenic diseases, which come from mutations in a single gene, are ideal for gene correction using CRISPR-Cas systems because they have well-defined genetic causes. Hemoglobinopathies, such as Sickle Cell Disease (SCD) and Beta-Thalassemia, have been extensively studied, as they stem from mutations in the HBB (beta-globin gene), which will either disrupt the structure of haemoglobin or inhibit its expression resulting in severe anaemia, damage to organs, and a marked restriction in life span. Current approaches involving SCD patients, such as blood transfusions, iron chelation therapy and bone marrow transplant are more or less effective, but none are curative and are possibly confounded because of either negative consequence of treatment or need for transplant donor. The availability of

CRISPR-Cas9 as a potentially curative procedure, offers the possibility to correct the gene defect (therapeutically) or alternatively, reactivate compensatory signalling pathways. One exciting strategy leverages the more universally applicable CRISPR, a novel biotechnology tool, to directly disrupt BCL11A, a direct transcriptional repressor of fetal haemoglobin (HbF). In normal individuals, HbF is postnatally replaced with adult haemoglobin (HbA), however, it is further understood that even in elevations HbF can provide clinical benefits as it compensates for defective β-globin, and therapeutic sites of action are likely 656 all of this. Further, by editing the enhancer region of the BCL11A gene in hematopoietic stem and progenitor cells (HSPCs), CRISPR provides a way to derepress HbF. As seen in ex vivo, CRISPR-edited HSPCs provide substantial clinical promise. Early-phase trials such as CTX001, remain promising, with early trial participants achieving transfusion independence and near-normal haemoglobin after reinfusion of their autologous CRISPR-edited HSPCs.

Base editing or prime editing whether allele-specific correction of point mutations on the HBB gene itself presents a more direct avenue to permanent genetic correction without intentionally making double-stranded breaks.CRISPR-Cas9, specifically, can convert the pathogenic A>T mutation resulting in SCD (Glu6Val) back to wild-type. These strategies minimize the potential for off-target modification, large deletions or chromosomal rearrangements making it preferable on the safety front for therapeutic applications of genome editing now and in the future. As a result, investigators are able to use CRISPR technology to conduct high-throughput genetic screens for the purpose of learning about additional modifiers of disease severity in haemoglobin opathies e.g. KLF1, ZBTB7A, and other regulators of erythroid differentiation and haemoglobin switching which have direct contributed to establishing multiplex editing strategies for combining multiple edits, of benefit to ultimate gene therapy and therapeutically synergistic opportunities. In addition to treating blood disorders, similar CRISPR-based strategies are being investigated for cystic fibrosis (CF), Duchenne muscular dystrophy (DMD) and inherited retinal dystrophies, where the intent of the editing strategy is precise correction or exon skipping to restore the functional expressed protein. These approaches illustrate the versatility and capability of CRISPR as a platform to address an array of inherited diseases at the genetic level. As might be expected, challenges still need to be addressed in all CRISPR-based therapies, including, but not limited to, optimal delivery mechanisms (e.g., viral vectors, lipid nanoparticles), long-term expression and engraftment of edited cells, and immunogenicity and off-target effects. But if CRISPR-marked therapeutics can permanently correct disease-causing mutations, it holds promise to be a game changer, bringing effective gene therapeutics closer to clinical reality for the millions suffering from serious genetic disorders.

Future Directions and Challenges

Although CRISPR and pharmacogenomics represent a thrilling possibility for the curative treatment of monogenic blood disorders, a number of obstacles still remain. The efficient delivery of CRISPR components (CRISPR tools) remains a considerable challenge. Most of the current methods including viral vectors, lipid nanoparticles, and electroporation, are being investigated to deliver CRISPR tools into hematopoietic stem cells to allow gene editing. A major research goal is to identify a targeted delivery method that minimizes immune responses and maximizes cellular uptake. In addition, as gene therapies transition from the laboratory to clinical applications, it will be important to consider long-term monitoring and safety of CRISPR-edited cells. Genotoxicity, immune rejection and mosaicism (in which some cells are not edited) will pose important questions or concerns that need to be addressed to unlock the full therapeutic potential of CRISPR. Cost and access to gene-editing therapies represent a notable challenge in clinical centres, especially in low-resource environments. For CRISPR-based therapies to be used widely for monogenic blood disorders, careful attention must be paid to healthcare infrastructure. At the same time, if CRISPR-based therapies became available for all individuals living with blood disorders, healthcare systems ought to also provide equitable access to the synchronous clinical adoption of these novel therapies.

Ethical Challenges

There are numerous ethical concerns regarding CRISPR and pharmacogenomics. One of the most controversial topics is germline editing, which is the editing of the DNA in an embryo or reproductive cell. Somatic gene editing (which only affects the patient) is more easily accepted than germline editing because germline editing may lead to multiple

generations of modification, significantly concerning reviewers. The notion of designer babies where germline modifications have been created for non-therapeutic purposes (such as intelligence or physical appearance) adds to the current unease with eugenics and exacerbates genetic inequality concerns as well. Along with issues surrounding the ethics of gene therapies are legal issues surrounding the ability to acquire proper informed consent with gene therapies. Informed consent will be highly complex for gene therapies, as most all gene changes will have a long long-term effect, there might be indirect off-target mutations because of the CRISPR process, and because of the overall uncertainty. Patients must be aware of the risks associated with CRISPR, including with data security issues that arise with obtaining, storing, and using patient genomic information in regards to data use, misuse and de facto discrimination.

CONCLUSION

The intersection of CRISPR-Cas9, pharmacogenomics, and artificial intelligence is a critical step forward in the timeline of a true personalized medicine. These technologies are already changing treatment methods for single gene disorders such as cystic fibrosis and sickle cell anemia and will subsequently transform the landscape for drug safety, effectiveness, and personalization. Although there are still obstacles such as off-target effects, delivery methods, ethical issues, and a lack of regulatory clarity, advances in AI-based design, base/prime editing, and epigenetic profiling are developing rapidly to overcome these challenges. As we embark on this journey toward a genomic revolution, it is necessary to practice prudency with equity, ethical framework and clinical opportunity in mind. By taking this collaborative, multi-disciplinary approach, the future of medicine is about more than just treatment it's about personalized transformation. It is now time to move from a "one-size-fits-all" model to "genes-to-dose" precision where every treatment may be unique to one patient.

ABSTRACT

This review paper explores the synergy between Network Functioning Virtualization (NFV) and Software Defined Network (SDN), highlighting their combined potential to create fully programmable networks architecture. To delve into the fundamental principles and architectures of both, a comprehensive analysis of their complementary roles are provided. The synergy is meant for dynamic service chaining, on-demand network slicing, and real-time traffic management, those are considered as the challenges of performance overheads, security risks, and interoperability issues. The included case studies and comment on the performance analysis introduces the valuable insights to enhance the integration, standardization of network infrastructures towards fully programmable, agile, and efficient networks. The novelty of this paper is to enlighten researchers about a recently developed innovative frameworks and architectural models of a fully programmable, proof of network infrastructures and it's driving advancements in cloud services, 5G, and beyond.

Keywords: Software Defined Network, Network Functioning Virtualization, Cloud Service Models, 5G Network.

INTRODUCTION

Modern network demands complex hybrid architecture, virtualization, scalability with increased system performance. However, traditional hardware-centric network infrastructure is struggling to keep up with the

dynamic and diverse requirements of those digital services such as digital service provisioning Iaas, PaaS, SaaS, DbaaS for flexible and adaptable network infrastructure [1]. Two promising technologies Network Function Virtualization (NFV) and Software-Defined Networking (SDN) are came up with various advantages. Though these two technologies face some challenges such as security concerns, complexity in management, performance and latency sensitivity when they are used in networks. So, they have emerged as transformative solutions to address those challenges [2]. NFV decouples network functions from proprietary hardware, allowing them to run on standard servers as virtualized services. This enables flexible and cost-effective deployment of network functions, reducing the need for specialized hardware [1]. On the other hand, SDN introduces a centralized control plane that separates the control logic from the underlying hardware, providing a high degree of programmability, automation, and real-time network management. Despite their individual benefits, the full potential of these technologies remains untapped without a synergistic integration. The primary problem lies in the lack of standardized frameworks and architectures to seamlessly combine NFV's agility with SDN's programmability, creating a fully programmable network infrastructure [3]. This gap leads to inefficiencies in resource utilization, suboptimal network performance, and increased operational complexities. The challenge is to explore and develop integrated solutions that leverage both NFV and SDN to create fully programmable networks, enabling dynamic service provisioning, real-time adaptability, and efficient resource management across diverse network environments [1].

This paper begins with a comprehensive literature review that provides an in-depth analysis of the current state of Network Functions Virtualization (NFV) and Software-Defined Networking (SDN) technologies. The review will highlight the unique advantages of each technology, such as NFV's ability to virtualize network functions, providing flexibility and cost savings, and SDN's centralized control, which allows for more programmable and automated network management. [1] However, it will also address the limitations of each technology, such as the complexity of SDN's centralized control and the scalability challenges in NFV deployments. This foundation will establish a clear understanding of how these technologies, when combined, can lead to a more dynamic and efficient network infrastructure, unlocking the potential for greater flexibility, scalability, and cost efficiency [2]. The next focus of this paper is on the architectural integration of NFV and SDN. A key contribution will be the development of an architectural model that illustrates how the agility of NFV in virtualizing network functions can complement the centralized programmability of SDN. By proposing mechanisms for seamless orchestration, management, and deployment, this model will demonstrate how the two technologies can work together to streamline network operations. [3] The integration will be explored in terms of service chaining, dynamic provisioning, and resource management, ensuring that the combination of NFV and SDN can offer a more flexible and automated network design, capable of adapting to evolving service demands and network conditions.

Practical use cases and applications will also be explored, showcasing where and how the integration of NFV and SDN has already been or could be implemented. [4] These use cases will highlight the transformative potential of these technologies in emerging areas such as 5G, edge computing, and cloud services. For example, the combination of NFV and SDN can enable more flexible and scalable 5G networks, facilitate dynamic resource allocation in edge computing environments, and enhance service orchestration in cloud platforms. Real-world applications will be used to illustrate the tangible benefits of this integration, demonstrating how it can provide more efficient and responsive network architectures for both service providers and end users.[5] Despite the promising potential of NFV and SDN integration, several challenges remain. This paper will identify key technical and operational hurdles that hinder the full realization of this integration. Issues such as interoperability between different NFV and SDN platforms, security concerns related to virtualized network functions, and performance bottlenecks due to centralized control will be addressed. Furthermore, the paper will propose potential solutions to these challenges, such as adopting common standards and protocols, enhancing security frameworks, and optimizing performance through distributed control mechanisms. [6] These discussions will also highlight areas for future research, such as improving cross-layer optimization and automating fault detection and recovery.

Finally, the paper will look forward to the future of NFV and SDN integration, considering how artificial intelligence (AI) and machine learning (ML) could play a key role in advancing network automation, fault management, and

service provisioning. AI and ML have the potential to improve network decision-making, predict failures, and enable proactive adjustments in real-time, enhancing the performance and efficiency of integrated NFV-SDN networks. [7] The paper will outline these future research directions and explore how evolving technologies could further drive innovation in the design of fully programmable, self-optimizing networks. By examining these developments, the paper aims to contribute to a deeper understanding of how the synergy between NFV and SDN can shape the next generation of network infrastructures [8]. This research paper explores the integration of Network Functions Virtualization (NFV) and Software-Defined Networking (SDN) to create a unified, fully programmable network architecture. Section 1 provides a comprehensive literature review of NFV and SDN, highlighting their individual benefits and limitations, setting the foundation for their synergistic potential. Section 2 presents an architectural model demonstrating how NFV's flexibility in virtualizing network functions complements SDN's centralized programmability, focusing on seamless orchestration, management, and deployment of services. Section 3 explores practical use cases in emerging technologies like 5G, edge computing, and cloud services, showing how the integration of NFV and SDN can address real-world challenges and deliver scalable, dynamic solutions. Section 4 identifies key challenges such as interoperability, security, and performance bottlenecks, offering potential solutions and suggesting areas for future research. Finally, Section 5 outlines future directions, highlighting how artificial intelligence (AI) and machine learning (ML) could enhance network automation, fault management, and service provisioning, further advancing the integration of NFV and SDN toward a fully programmable network ecosystem [9].

In the paper, by delving into the integration of Network Functions Virtualization (NFV) and Software-Defined Networking (SDN) to create a unified, fully programmable network architecture concept is explored. Major contribution will focus on the following key areas:

- **Comprehensive Literature Review:** It will provide an in-depth review of the current state of NFV and SDN technologies, highlighting their individual benefits and limitations in [9]. This will set the foundation for exploring how these two technologies can be synergistically combined to achieve greater network flexibility, scalability, and cost efficiency.
- **Architectural Integration:** It will contribute to developing an architectural model that demonstrates how NFV's agility in virtualizing network functions can complement SDN's centralized programmability [10]. This will include proposing mechanisms for seamless orchestration, management, and deployment of network services using both technologies.
- **Use Cases and Applications:** In [3,4], the works will explore and document practical use cases where the integration of NFV and SDN has been or could be implemented. These examples will showcase the potential for real-world applications, particularly in emerging technologies such as 5G, edge computing, and cloud services.
- **Challenges and Solutions:** In [1,2,4],the works will identify the major technical and operational challenges that hinder the full integration of NFV and SDN, such as interoperability, security, and performance bottlenecks. I will also suggest potential solutions or areas of future research that could address these issues.
- **Future Directions:**In [10,11], the works will outline the future research directions for further advancing the integration of NFV and SDN, considering how evolving technologies like artificial intelligence and machine learning can enhance network automation, fault management, and service provisioning.

Overview of Traditional Network Architectures

Traditional network architectures are built around hardware-centric designs where network functions are tied to specific hardware devices. These functions include routing, switching, firewalling, load balancing, and other network services. The key components of traditional networks include: (1) Routers and Switches: the devices are responsible for directing traffic within and between networks. (2) Firewalls: These provide security by controlling incoming and outgoing network traffic based on predetermined security rules. (3). Load Balancers: - These distribute network or application traffic across multiple servers to ensure no single server becomes overwhelmed. (4) Network Appliances: - Dedicated hardware devices that provide specific network functions such as VPNs, intrusion detection/prevention systems (IDS/IPS), etc.

Limitations of Traditional Network Architectures

Due to advent of technology and technological complexity with growing number of parallelism in program executions, the following limitations are also affected the traditional framework as well as network architecture, such as: (1) Hardware Dependency: - Network functions are tied to specific hardware devices, making the network less flexible and harder to manage. Upgrading or scaling often requires purchasing new hardware, which can be costly and time-consuming. (2) Complex Management: - Managing a large number of disparate devices with different interfaces and management tools adds complexity. Configuring and maintaining these devices requires significant manual effort and expertise. (3) Scalability Issues: - Scaling up requires additional hardware, leading to increased costs and physical space requirements. Scaling out (horizontal scaling) can be particularly challenging due to the rigid hardware dependencies. (4) Slow Deployment: - Deploying new services or making changes to the network can be slow because it often involves configuring physical devices, which may require downtime. (5) Lack of Automation: - Traditional networks have limited support for automation, leading to potential human errors and slower response times to network changes or issues. (6) Inflexibility: - The static nature of traditional networks makes them less adaptable to changing business needs or emerging technologies. Changes often require extensive reconfiguration or hardware replacement.

Development of NFV (Network Function Virtualization)

Network Function Virtualization (NFV) emerged as a solution to overcome the limitations of traditional network architectures by decoupling network functions from dedicated hardware devices (as shown in Fig. 1). Key aspects of NFV include: (1) Virtualization of Network Functions: - Network functions such as firewalls, load balancers, and routers are implemented as software applications (Virtual Network Functions or VNFs) running on standard servers or virtual machines instead of specialized hardware. (2) Flexibility and Agility: - NFV allows for rapid deployment and scaling of network services. VNFs can be easily deployed, updated, and managed, offering greater agility in responding to changing network demands. (3) Cost Efficiency: - By using standard server hardware instead of specialized devices, NFV can reduce capital and operational expenditures. (4) Simplified Management: - Centralized management platforms can orchestrate and manage VNFs, simplifying network management and reducing the need for specialized hardware expertise.

Development of SDN (Software-Defined Networking)

Software-Defined Networking (SDN) complements NFV by providing a framework for more flexible and programmable network management (as shown in Fig. 2). Key aspects of SDN include: (1) Separation of Control and Data Planes: - SDN separates the network control plane (which makes decisions about where traffic is sent) from the data plane (which forwards traffic to the selected destination). This separation allows for centralized control and management of the network. (2) Centralized Network Control: - SDN uses a centralized controller to manage network traffic, enabling more efficient traffic management, improved network visibility, and easier implementation of policies across the network. (3) Programmability: - SDN allows network administrators to programmatically control and manage the network through APIs, enabling dynamic adjustment of network behaviour to meet changing requirements. (4) Automation and Orchestration: - SDN enables greater automation of network configuration and management, reducing manual intervention and the potential for human error. It allows for automated network provisioning, configuration, and management, improving efficiency and reducing operational costs.

Combined Benefits of NFV and SDN

Together, NFV and SDN address the limitations of traditional network architectures by: (1) Enhancing Flexibility: - By decoupling network functions from hardware and enabling programmable network management, networks become more adaptable to changing requirements. (2) Improving Scalability: - Both technologies facilitate easier and more cost-effective scaling of network services. (3) Speeding Deployment: - New network services can be deployed quickly and dynamically without the need for extensive hardware changes. (4) Reducing Costs: - Standardizing on commodity hardware and automating network management reduce both capital and operational expenditures. (5)

Enabling Innovation: - The programmable nature of SDN and the flexibility of NFV create an environment conducive to innovation, allowing organizations to quickly adopt and implement new technologies and services

LITERATURE REVIEW

In [14], the researchers outlined the challenges and opportunities of NFV, emphasizing its potential to transform network service delivery by leveraging virtualization technologies. In an another survey paper, an overview of NFV research, covering various aspects such as architecture, deployment scenarios, and performance issues, are provided [13]. Software-Defined Networking (SDN) faces several challenges, including security concerns due to centralized control points that can attract attacks, and implementation complexities arising from the need to integrate with legacy systems and a lack of expertise. [1] Performance issues may arise from potential latency and scalability challenges in large deployments, while interoperability risks include vendor lock-in and the absence of universal standards. Additionally, network reliability can be compromised by software bugs and controller downtimes. Managing Quality of Service (QoS) is complicated by dynamic resource allocation, and regulatory compliance may pose data privacy concerns. Lastly, the high initial investment and potential increase in ongoing operational costs can be significant barriers to adoption. [2] Network Function Virtualization (NFV) faces several challenges, including performance overheads that may introduce latency compared to traditional hardware solutions, and the complexity of managing a virtualized environment which requires advanced orchestration and automation tools. Interoperability issues arise due to varying standards from different vendors, while security vulnerabilities can emerge from new attack surfaces in virtualized settings. Effective resource management is crucial to avoid performance degradation or wastage, and network reliability can be compromised by software bugs or configuration errors. Additionally, the transition to NFV may require new skills that existing staff may lack, complicating implementation, and ensuring regulatory compliance can be challenging, especially in regulated industries. Furthermore, organizations risk vendor lock-in with specific VNF providers, and while NFV can offer long-term savings, the initial investment in infrastructure and training can be substantial. [1,3]

Network operators are under pressure to offer efficient services while minimizing deployment costs. Network Functions Virtualization (NFV) offers a revolutionary approach by decoupling network functions from proprietary hardware and running them on standard servers, leading to reduced costs and enhanced flexibility. Despite continuous efforts from academia and industry, NFV solutions are still in their early stages. The survey provides a comprehensive overview of NFV, covering its main concepts, benefits, and architecture as defined by the European Telecommunications Standardization Institute (ETSI). [4] It discusses current NFV applicability, standardization efforts, and key open-source projects. NFV is crucial for the evolution of 5G, particularly in enabling network slicing. However, significant challenges, including fault management, security, and interoperability, remain unresolved, hindering widespread commercial deployment. [5]

The text emphasizes the importance of selecting the right hypervisor (Type I or Type II) for efficient utilization of virtual environments. NFV offers benefits such as flexibility, manageability, and security in network virtualization, but numerous technical barriers must be overcome, including achieving "Five 9s" reliability (99.999%) similar to Public Switched Telephone Networks (PSTN) [6], Future directions for NFV include addressing key research challenges such as fault management, network automation, and end-to-end reliability. The article encourages further research to address these challenges, ultimately pushing NFV into mainstream network deployments, potentially revolutionizing the telecommunications industry by working alongside Software-Defined Networking (SDN) and cloud technologies. [1,2,3] By focusing on these contributions, this research paper offers valuable insights into how NFV and SDN can jointly pave the way towards a more dynamic, programmable, and cost-efficient network infrastructure for the future. Modern network demands for complex hybrid architectures, virtualization, scalability, and enhanced performance are challenging traditional hardware-centric infrastructures, particularly in delivering digital services like IaaS, PaaS, SaaS, and DbaaS. To address these challenges, Network Function Virtualization (NFV) and Software-Defined Networking (SDN) have emerged as transformative technologies, offering advantages such as

flexibility, cost-effectiveness, and programmability. [10] NFV decouples network functions from proprietary hardware to run on standard servers, while SDN introduces a centralized control plane for automated and real-time network management. However, the full potential of these technologies remains largely untapped due to the lack of standardized frameworks for their integration, leading to inefficiencies in resource utilization and increased operational complexities. [11] The primary challenge is to develop integrated solutions that synergistically combine NFV's agility with SDN's programmability to create fully programmable networks capable of dynamic service provisioning and efficient resource management [9].

Use Cases and implementation techniques

This section summarizes NFV and SDN technologies from the perspectives of practical implementation techniques. The various constructions are sole or combined for refinement of network activities.

The derived concepts are implemented in various kinds of networking configurations, such as:

- **Dynamic Service Chaining:** NFV and SDN enable dynamic service chaining, allowing operators to dynamically instantiate and chain together VNFs to create custom service paths tailored to specific service requirements or user demands. [24]
- **On-Demand Network Slicing:** NFV and SDN enable on-demand network slicing, allowing operators to dynamically partition network resources to create isolated virtual networks (slices) tailored to specific use cases or service requirements. [25]
- **Real-Time Traffic Management:** NFV and SDN enable real-time traffic management, allowing operators to dynamically adjust network resources and routing policies in response to changing traffic conditions, congestion, or security threats, ensuring optimal performance and reliability. [26]
- **AT&T's Domain 2.0 Initiative**: AT&T has been a pioneer in implementing NFV and SDN synergy through its Domain 2.0 initiative. By virtualizing network functions and leveraging SDN principles, AT&T has transformed its network infrastructure, making it more flexible, scalable, and cost-effective. This has enabled AT&T to rapidly deploy new services and improve network performance for its customers.
- **Verizon's Virtual Network Services**: Verizon has also embraced NFV and SDN to deliver virtualized network services to its enterprise customers. By decoupling network functions from underlying hardware and centrally orchestrating them through SDN controllers, Verizon can offer a wide range of services on-demand, including virtual firewalls, routers, and WAN optimization. [23]
- **Telefónica's UNICA Platform: Telefónica's UNICA** (Universal IT Cloud) platform is another example of NFV and SDN synergy in action. By virtualizing network functions and leveraging SDN for network automation and orchestration, Telefónica has been able to improve service agility, reduce time-to-market, and optimize resource utilization across its global network infrastructure.

In Practice or Implementation surveys

Network Functions Virtualization: Challenges and Opportunities (2013): This foundational paper outlined the challenges and opportunities of NFV, emphasizing its potential to transform network service delivery by leveraging virtualization technologies. [22]

A Survey of Network Function Virtualization (2015): This survey paper provided an overview of NFV research, covering various aspects such as architecture, deployment scenarios, and performance issues. [20]

Open Flow: Enabling Innovation in Campus Networks (2008): This seminal paper by Nick McKeown et al. introduced Open Flow, laying the foundation for SDN by describing how a standardized protocol could enable programmable network control. [19]

The (R) Evolution of SDN (2014): This paper discussed the evolution of SDN, from its early days with Open Flow to its broader applications and impact on networking. [21]

Further, Integration and Combined Benefits are cited in below mentioned researches, such as:
Research and industry (2014-2016) focus shifted towards integrating NFV and SDN to leverage their complementary strengths. NFV's virtualized network functions and SDN's programmable control planes together promised more flexible, scalable, and efficient network architectures.
A Comprehensive Survey on NFV/SDN Architectures, Applications, and Challenges" (2015): This survey paper reviewed the integrated architecture of NFV and SDN, discussing how their synergy could address various network challenges and enable new applications.

Industry Developments

These subsection throws light on the deployment or used concepts of SDN and NVF in IT and Telecomm Industry.
ETSI NFV ISG: The establishment of the ETSI NFV Industry Specification Group (ISG) led to the development of a reference architecture for NFV, defining essential components like Virtual Network Functions (VNFs), NFV Infrastructure (NFVI), and the NFV Management and Orchestration (MANO) framework.
Commercial Deployments: By the mid-2010s, major telecom operators began deploying NFV solutions, driven by the need for more agile and cost-effective network services.
Open Networking Foundation (ONF): Founded in 2011, the ONF spearheaded the standardization of SDN and OpenFlow, driving industry adoption and development.
SDN Controllers: The development of SDN controllers like NOX, Floodlight, and OpenDaylight enabled centralized network control and programmability, facilitating more efficient and flexible network management.

Industry Momentum

Standardization Efforts: Collaboration between ETSI NFV ISG and ONF aimed to ensure interoperability and standardization in the implementation of NFV and SDN.
Commercial Solutions: Vendors began offering integrated NFV and SDN solutions, and telecom operators started deploying these technologies to achieve more agile, cost-effective, and scalable networks.

Future Direction

Let's delve into the future directions of NFV and SDN integration, which provides research opportunities to the other researchers of this domain.

Technological Advancements without AIML techniques

The next generation technologies such as service function chaining (SFC), Security for SDN/NFVorSDN/NFV Security Solutions and Edge Computing Integration are as follows:

- Service Function Chaining Optimization: Research can focus on optimizing service function chaining (SFC) in NFV-enabled SDN networks. This includes developing algorithms and policies to dynamically orchestrate and manage service chains based on real-time traffic conditions, application requirements, and network resources [12].
- SDN/NFV Security Solutions: There's a need for research into enhancing security and privacy in NFV and SDN environments. This involves exploring novel approaches for securing virtualized network functions, detecting and mitigating threats in software-defined networks, and ensuring compliance with regulatory requirements [13].
- Edge Computing Integration: With the proliferation of edge computing, there's an opportunity to explore the integration of NFV and SDN with edge computing platforms. Research can focus on enabling efficient deployment and management of virtualized network functions at the network edge, leveraging SDN principles for network slicing and resource orchestration [14].

Technological Advancements through AIML

AI and Machine Learning: Integration of artificial intelligence (AI) and machine learning (ML) techniques can enhance the synergy between NFV and SDN. AI/ML algorithms can be used for network optimization, predictive

analytics, anomaly detection, and automated network management, leading to improved performance, efficiency, and reliability.

Containerization and Micro services: Adoption of containerization and Micro services architectures can further enhance the flexibility and scalability of NFV and SDN deployments. By containerizing virtualized network functions and leveraging Micro services principles, organizations can achieve greater agility, faster deployment times, and easier management of complex network services. [15]

Quantum Networking: In the long term, advancements in quantum networking could revolutionize NFV and SDN integration. Quantum technologies offer the potential for ultra-secure communication, massive parallelism, and unprecedented scalability, which could be leveraged to create highly resilient and efficient virtualized network infrastructures. [16]

Standardization Efforts:
To continue with uniform networking in a telecommunication system, various standardization platforms are formed. These organizations are as follows:

ETSI NFV ISG: The European Telecommunications Standards Institute (ETSI) NFV Industry Specification Group (ISG) continues to work on defining standards and specifications for NFV architectures, interfaces, and APIs. Ongoing efforts include enhancing interoperability, performance, and reliability of NFV deployments. [17]

ONF and Open Source Initiatives: The Open Networking Foundation (ONF) and various open-source projects (e.g., ONAP, OPNFV) are driving standardization efforts and fostering collaboration in the NFV and SDN ecosystem. These initiatives aim to develop open standards, [reference architectures, and interoperable implementations that accelerate innovation and adoption of NFV and SDN technologies. [18]

IETF and IEEE: The Internet Engineering Task Force (IETF) and the Institute of Electrical and Electronics Engineers (IEEE) are also actively involved in standardization efforts related to NFV and SDN. These organizations develop protocols, data models, and best practices for network virtualization, programmability, and automation, which are essential for enabling interoperability and scalability in heterogeneous network environments. Besides various benefits of the combined techniques, some challenges are incurred: (1) Virtualization Overhead: Virtualizing network functions (VNFs) can introduce latency and reduce performance compared to hardware-based solutions. Resource contention between VNFs sharing the same physical infrastructure can affect performance and reliability. Additionally, the centralized SDN controller may become a bottleneck in large-scale deployments with high traffic volumes. (2) Security Risks: The centralization of SDN control and abstraction layers in NFV increase the attack surface, making SDN controllers and NFV orchestrators vulnerable to attacks. Proper isolation between VNFs is essential to prevent data leaks and unauthorized access. Trust management is also challenging, particularly when using third-party components or services. (3) Interoperability Issues: Vendor lock-in can occur due to proprietary SDN and NFV solutions, causing interoperability issues in multi-vendor environments. Despite efforts to standardize interfaces, discrepancies remain, complicating integration. Additionally, integrating SDN and NFV with legacy systems often requires complex modifications to existing infrastructure. (4) Management Complexity: SDN and NFV require complex orchestration for managing VNFs and virtualized infrastructure, which can be difficult to implement and maintain. Monitoring and troubleshooting are challenging due to the dynamic nature of these environments, often requiring advanced tools. Additionally, the need for specialized skills in SDN and NFV creates workforce gaps, leading to training and hiring challenges.

CONCLUSION

The aim of this paper is to explore the synergy between Network Function Virtualization (NFV) and Software-Defined Networking (SDN), examining how their combined implementation can address the limitations of traditional network architectures. Specifically, the paper will investigate how NFV and SDN together enhance network flexibility, scalability, and cost-efficiency, while enabling rapid deployment and innovation. Through this exploration, the paper seeks to provide a comprehensive understanding of the integrated benefits and potential challenges of leveraging NFV and SDN in modern network environments.

Table 1: Comparative study between SDN (Software-Defined Networking) and NFV (Network Functions Virtualization)

Aspect	SDN (Software-Defined Networking)	NFV (Network Functions Virtualization)
Primary Focus	Decouples control plane from data plane to enable centralized, programmable network control	Virtualizes network functions traditionally run on dedicated hardware
Core Concept	Centralized control with a software-based SDN controller	Virtualization of network functions (e.g., firewall, router) onto commodity hardware
Main Goal	Network programmability, flexibility, and automation	Reduce hardware dependency and enable rapid deployment of network services
Network Layer	Primarily works at Layer 2 (Data Link) and Layer 3 (Network)	Operates at multiple layers including Layer 3 (IP), Layer 4 (Transport), and Layer 7 (Application)
Component Focus	SDN controller, APIs, and traffic forwarding devices	Virtual Network Functions (VNFs), NFV orchestrator, virtualized infrastructure manager (VIM)
Hardware Dependency	Minimizes hardware dependency by centralizing control	Reduces hardware dependency by virtualizing network appliances
Service Creation/Modification	Dynamic and programmable traffic management and network policies	Rapid creation, deployment, and scaling of virtualized network services (e.g., firewall,

		load balancing)
Key Technologies	Open Flow, SDN controllers, Southbound APIs, Northbound APIs	Virtual machines (VMs), containers, cloud platforms, VNF orchestration
Resource Management	Manages data traffic, forwarding tables, and path selection	Manages virtualized compute, storage, and network resources for VNFs
Deployment Environment	Data centers, wide-area networks, SD-WAN	Telecom networks, data centers, enterprise networks, edge computing
Service Agility	Provides agile traffic management and network reconfiguration	Allows for faster deployment of network functions and services
Scalability	Can scale horizontally with distributed controllers, but centralized control may face bottlenecks	Can scale by dynamically allocating more virtual resources for VNFs
Performance	Can improve performance via optimized traffic flows but may face bottlenecks in very large deployments	Performance may suffer from virtualization overhead if not properly optimized
Security	Security concerns around the centralized SDN controller, potential attack surface at control plane	Security concerns include virtual machine/container isolation, hypervisor vulnerabilities, and VNF security
Cost Efficiency	Cost savings due to centralized control, reduced hardware needs	Cost savings from using commodity hardware, avoiding expensive physical appliances
Flexibility	High flexibility in network management and path selection	High flexibility in deploying and scaling network functions on demand
Key Use Cases	Data center networking, SD-WAN, network slicing, cloud networks	Telecom infrastructure, enterprise networks, edge networks, cloud services
Controller vs. Orchestrator	SDN uses a controller to manage network traffic	NFV uses an orchestrator to manage VNFs and virtualized resources
Traffic Flow Control	Directly controls traffic flow across network paths via SDN controller	NFV does not directly control traffic flows; it provides the virtualized network functions for handling traffic
Integration with Other Systems	Can integrate with orchestration systems for end-to-end automation	NFV often requires integration with SDN to provide complete network automation

ABSTRACT

Nilavagai Chooranam is a classical Siddha polyherbal formulation traditionally indicated for anorectal disorders (*Moola Noygal*). Despite its long-standing therapeutic use, the absence of standardized quality control parameters and variations in raw material processing limit its reproducibility and wider regulatory acceptance. The present study aimed to establish pharmaceutical and analytical characterization standards for *Nilavagai Chooranam* in accordance with WHO and AYUSH guidelines. The formulation was prepared as per the classical text *Brammamuni Karukkidai Choothiram* using authenticated raw materials and traditional purification procedures. Organoleptic, physicochemical, biochemical, phytochemical, chromatographic, and microbial analyses were performed. The formulation appeared as a fine greenish-brown aromatic powder without foreign matter. Physicochemical evaluation showed low moisture content (LOD: 2.187%), total ash (6.9%), and acid-insoluble ash (0.18%), indicating good purity and minimal contamination. The pH was mildly acidic (5.8). Water-soluble extractive value (39.51%) was higher than alcohol-soluble extractive value (11.11%), suggesting predominance of polar phytoconstituents. Biochemical analysis confirmed the presence of chloride, ammonium, iron, and sodium ions, while toxic heavy metals such as arsenic and mercury were absent. Preliminary phytochemical screening revealed flavonoids, tannins, phenolic compounds, carbohydrates, reducing sugars, and phytosterols. TLC and HPTLC analyses demonstrated distinct and reproducible fingerprint

profiles at multiple wavelengths. Microbial load was within permissible limits, and aflatoxin estimation showed minimal contamination (2.1 ppb), supporting the microbiological safety of the formulation. Overall, *Nilavagai Chooranam* exhibited acceptable purity, stability, and safety parameters, thereby supporting its traditional use and providing a scientific basis for future pharmacological and clinical studies.

Keywords: Siddha Medicine, *Nilavagai Chooranam* , Physicochemical Analysis, High-Performance Thin Layer Chromatography, Phytochemical Screening, Hemorrhoids

INTRODUCTION

The Siddha system of medicine is one of the most ancient and continuous traditional medical sciences. It is fundamentally based on the macrocosm–microcosm concept, wherein the human body mirrors the universe and is constituted by *96 Thathuvams* that encompass all physical, physiological, mental, and intellectual dimensions.[1]In Siddha literature diseases are classified 4,448 distinct conditions. Among these, anorectal disorders (Moola Noygal) represent a highly prevalent group, affecting approximately 5–15% of the global population, with hemorrhoids alone having a lifetime prevalence of nearly 50%.[2] In India, rising sedentary habits and low-fiber diets further increase disease burden, with hemorrhoids accounting for 42% of anorectal cases, followed by fistula, pilonidal sinus, abscess, and fissure.[2], [3] Contributing factors include improper diet, suppression of natural urges, and psychological stress, and increased anorectal pressure resulting in vascular engorgement and hemorrhoidal pathology. [4], [5]
In this context, *Nilavagai Chooranam* , described in *Brammamuni Karukkidai Choothiram* (pp. 68–69), is a classical Siddha polyherbal formulation indicated for *Malakkattu, Moola noygal*, and related conditions, acting through mild purgation, and anti-inflammatory effects, administered in a dose of *Verukadi alavu* for one *Mandalam* (48 days) following proper Suddhi procedures to ensure safety and enhanced bioavailability. [6] The growing global interest in traditional medicine, due to its holistic approach and relatively lower adverse effects, is counterbalanced by concerns regarding variability and lack of quality control in herbal formulations[7],[8]. Unlike traditional physician-controlled preparation, modern large-scale manufacturing introduces variations due to geographical sourcing, seasonal changes, storage conditions, and adulteration[7],[9]. Hence, pharmacological characterisation becomes essential to establish defined physicochemical and analytical parameters ensuring identity, purity, safety, and efficacy.[9] International and national regulatory bodies, including WHO and Indian institutions such as AYUSH, PCIM&H, and PLIM, have established guidelines and pharmacopoeial standards, with GMP compliance mandated under the Drugs and Cosmetics Act, 1940 and Rules, 1945 (Schedule T) [10]. Therefore, the application of modern techniques—including physicochemical evaluation, biochemical assays, chromatographic fingerprinting (TLC/HPTLC), and microbial testing—to *Nilavagai Chooranam* is critical to ensure consistency, therapeutic reliability, regulatory compliance, and global acceptance as an evidence-based Siddha formulation. This article explores the pharmaceutical and analytical characterization of the *Nilavagai Chooranam* a polyherbal formulation.

MATERIALS AND METHODS

Drug Formulation:

Internal medicine : *NILAVAGAI CHOORANAM*

Ingredients :

Nilavagai (Cassia senna, Linn.*)*	*Sivadhai (Operculina turpethum,* Linn.*)*
Milagu (Piper nigrum, Linn.*)*	*Thalisapathiri (Abies spectabilis,* Mirb*)*
Kadukkai (Terminalia chebula, Retz*)*	*Jaadhikkai (Myristica fragrans,* Houtt*)*
Thaanrikkai (Terminalia bellerica, Roxb*)*	*Kiraambu (Syzygium aromaticum,* Linn.*)*
Seeragam (Cuminum cyminum, Linn.*)*	*Thippili (Piper longum,* Linn.*)*
Vaaluluvai (Celastrus paniculatus, Willd*)*	*Seviyam* (Root of *Piper nigrum,* Linn.*)*

Sirunaagapoo (Mesua nagassarium, Kosternm*)*	*Indhuppu (Sodii chloridum impura)*
Elam (Elettaria cardamomum, Maton*)*	*Koogaineeru (Maranta arundinacea,* Linn.*)*
Ilavangapattai (Cinnamomum verum, Presl	*Sukku (Zingiber officinale,* Rosc*)*
Kadugurogini (Picrorhiza scrophulariiflora, Pennell*)*	*Seeni Sarkkari (Saccharum officinarum,* Linn.*)*

Dosage : *Verukadi alavu* (1.375g). Twice a day. After food
Duration : *Orumandalam* (48 days)
Indications:

- *Malakkattu* (Constipation),
- *Vaaivu* (One of the three humours),
- *Soodu kollal* (Intense heat in pelvic region),
- *Sori & Sirangu* (A kind of itch or scabies),
- *Moolavaayu* (Accumulation of bowel gas),
- *Moola noygal* (Diseases of Anorectal region).

Raw Material Collection and Authentication (Figure 1)

Raw Drugs Procurement:

The Above Listed Raw Drugs Were Purchased From A Raw Drug Shop – Thakkalai, Kanyakumari.

Raw Drugs Authentication:

The Raw Drugs Were Authenticated By Botanist In Nis, Chennai. Certificate No: Nismb7132024 (02/11/2024)

Preparation

Purification Of Raw Drugs [12]:

- *Nilavagai(Cassia senna, Linn.)*- Powdered leaves was boiled in the steam of milk for 3 hours.
- *Milagu (Piper nigrum, Linn.)*- Soaked into the butter milk and dried.
- *Kadukkai(Terminalia chebula, Retz)* - Seeds was removed and dried.
- *Thaanrikkai (Terminalia bellerica,* Roxb*)* - Was soaked in Thazhaivizhuthu juice for 3 hours and the dried under sunlight.
- *Seeragam (Cuminum cyminum,* Linn.*)*- Was cleaned for impurities and dried under the sunlight.
- *Vaaluluvai (Celastrus paniculatus,* Willd*)*- Was washed in *Aloe barbedensis* juice then dried under the sunlight.
- *Sirunaagapoo (Mesua nagassarium,* Kosternm*)*- Was cleaned for impuritiesand dried under the sunlight.
- *Elam (Elettaria cardamomum,* Maton– Was cleaned for impuritiesand dried under the sunlight.
- *Ilavangapattai (Cinnamomum verum, Presl*–Was cleaned for impuritiesand dried under the sunlight
- *Kadugurogini (Picrorhiza scrophulariiflora,* Pennell*)*- Was soaked in Neem leaves juice for 3hours and dried under the sunlight
- *Sivadhai (Operculina turpethum,* Linn.*)*- The central veins from the root were removed boiled in milk then dried under the sunlight
- *Thalisapathiri (Abies spectabilis,* Mirb*)*–Was cleaned for impuritiesand dried under the sunlight
- *Jaadhikkai (Myristica fragrans,* Houtt*)*- the outer skin was peeled to make into small pieces and dried under the sunlight.
- *Kiraambu (Syzygium aromaticum,* Linn.*)*- Was cleaned for impuritiesand dried under the sunlight.
- *Thippili (Piper longum,* Linn.*)*- Was soaked in kodiveli leaf juice for 24 hours and then will be dried under sunlight.

- *Seviyam (*Root of *Piper nigrum,* Linn.*)*- Was cleaned for impurities and dried.
- *Indhuppu (Sodii chloridum impura)*– Was soaked in Fermented Rice[13] Liquidfor 3 days and dried under the sunlight.
- *Koogaineeru (Maranta arundinacea,* Linn.*)*- Was mixed with water and washed for seven times filtered and dried under the sunlight
- *Sukku (Zingiber officinale,* Rosc*)*–Was soaked in limestone water for 3 hours and outer layer was removed.
- *Seeni Sarkkari (Saccharum officinarum,* Linn.*)*- Was crushed and made into a fine powder.

Study Drug Preparation and Storage:

STEP 1 : After purification, the Main Ingredient *Nilavagai Chooranam* is dried and powdered nicely.
STEP 2 : After purification Part A and Part B drugs are made into fine powder.
STEP 3 : The powdered Main ingredient, Part A and Part B drugs are mixed together well.
Prepared medicine will be stored in an airtight container.

Pharmaceutical and Analytical Characterization (Procedures) (Table 1-4)

Organoleptic Character: Organoleptic Characters Are The Visual and sensory attributes used to describe, identify, and evaluate the genuineness of medicinal plant materials and crude drugs. These characteristics are assessed using the basic senses or by naked-eye observation. Organoleptic characters typically include: Sensory traits: Odour and taste. During testing, odour is typically evaluated by directly smelling a sample of the powdered drug, while taste is examined by applying a small quantity of the powder to the tongue using a moist glass rod. Visual and physical traits: Size, color, consistency, state (e.g., solid), appearance, surface characteristics (such as texture and fracture), touch, and flow properties

Foreign Matter: The entire contents of the packing if 100 g or less is removed, and spread in a thin layer in a suitable dish or tray. It is examined in daylight with unaided eye. Suspected particles are transferred, if any, to a petri dish, and examine with 10x lens in daylight.[14]

Physicochemical Properties: As per Characterisation and Standardization of herbal formulations: an overview (Baqai Journal of Health Sciences) and Protocol for testing of Ayurvedic, Siddha and Unani medicines (Department of AYUSH, 2008), the following physicochemical parameters are evaluated to ensure the quality, purity, and standardization of herbal drugs. [15],[16]

Loss On Drying At 105°C / Moisture Content

Loss on drying determines the amount of moisture and volatile components present in the drug by heating the sample at 105°C until constant weight is achieved, and calculating the percentage weight loss.

Total Ash: Total ash estimation evaluates the total inorganic residue remaining after complete incineration of the drug, thereby indicating the presence of physiological and non-physiological inorganic matter such as carbonates, phosphates, and silicates.

Acid-Insoluble Ash: Acid-insoluble ash measures the fraction of total ash that remains insoluble in dilute hydrochloric acid, primarily reflecting siliceous impurities like sand and soil contamination.

Ph (5% Aqueous Extract): The pH of a 5% aqueous extract is determined to assess the acidic, neutral, or alkaline nature of the formulation, which influences drug stability, absorption, and therapeutic activity.

Water-Soluble Extractive: Water-soluble extractive value indicates the proportion of active constituents soluble in water, such as sugars, acids, and mucilage, serving as an index of drug quality and potential adulteration.

Alcohol-Soluble Extractive: Alcohol-soluble extractive value estimates the amount of constituents like alkaloids, tannins, and resins extractable in alcohol, thereby helping to evaluate the chemical composition, purity, and standardization of the drug.

Bulk Density: Bulk density is the mass of a powder sample divided by its total volume (including particles, interparticle voids, and pores), generally expressed in grams per milliliter (or). It is critical for assessing powder flow, processing, packaging, and storage, often split into untapped (bulk) and tapped density to measure compressibility.[17]

Biochemical Analysis (Table 5,6)

Test For Acid Radicals

Ash Test: A filter parchment soaked in a mixture of the sample and cobalt nitrate solution was gradually introduced into a Bunsen flame and ignited; observations were recorded.

Test for Sulphate: To 2 ml of the extract, 2 ml of 4% ammonium oxalate solution was added and mixed; results were noted.

Test for Chloride: To 2 ml of the extract, dilute nitric acid (HNO_3) was added dropwise until effervescence ceased, followed by the addition of 2 ml of silver nitrate solution; observations were recorded.

Test for Phosphate: To 2 ml of the extract, 2 ml of ammonium molybdate solution and 2 ml of concentrated nitric acid (HNO_3) were added; results were noted.

Test for Carbonate: To 2 ml of the extract, 2 ml of magnesium sulphate solution was added; observations were recorded.

Test for Calcium: To 2 ml of the extract, 2 ml of 4% ammonium oxalate solution was added; results were noted.

Test for Magnesium: To 2 ml of the extract, sodium hydroxide solution was added dropwise and then in excess; observations were recorded.

Test for Ammonium: To 2 ml of the extract, a few millilitres of Nessler's reagent followed by excess sodium hydroxide solution were added; results were noted.

Test for Mercury: To 2 ml of the extract, 2 ml of sodium hydroxide solution was added; observations were recorded.

Test for Arsenic: To 2 ml of the extract, 2 ml of sodium hydroxide solution was added; results were noted.

Test for Iron: To 2 ml of the extract, 2 ml of ammonium thiocyanate solution was added and mixed; observations were recorded.

Test for Zinc: To 2 ml of the extract, sodium hydroxide solution was added dropwise and then in excess with stirring; results were noted.

Preliminary Phytochemical Analysis (Table 7,8)

Phytochemical screening is conducted to detect the presence and nature of biologically significant secondary metabolites (such as alkaloids, flavonoids, tannins, saponins, and steroids) within a crude drugas per Khandelwal (2008) and Kokate et al. (2008)[22], [23]. Identifying these chemical constituents helps establish the drug's quality and explains its potential therapeutic properties and pharmacological efficacy (e.g., flavonoids for antioxidant activity, alkaloids for antimicrobial effects). To perform these tests, a small quantity of the drug (typically a few milligrams or a 5 ml aliquot) is usually extracted or dissolved in a specific solvent (such as distilled water, ethanol, or chloroform). Solvents are chosen based on the solubility of the target phytochemicals so that they can be effectively released and react with the specific testing reagents. [18], [19], [20], [21]

- **Detection of Alkaloids**

a. Dragendorff's Test: The acidic extract, when treated with Dragendorff's reagent, produces an orange-red precipitate indicating alkaloids.

b. Wagner's Test: Addition of Wagner's reagent to the acidic extract yields a reddish-brown precipitate confirming alkaloids.

- **Detection of Carbohydrates**

Molisch's Test: Treatment with Molisch's reagent and concentrated sulfuric acid produces a reddish-violet color indicating carbohydrates.

- **Detection of Reducing Sugars**

a Fehling's Test: Heating the extract with Fehling's solutions A and B produces a brick-red precipitate indicating reducing sugars.

b. Benedict's Test: Heating the sample with Benedict's reagent produces a characteristic colored precipitate indicating sugars.

- **Detection of Glycosides**

10% NaOH Test: Addition of sodium hydroxide produces yellow, pink, or blood-red coloration indicating glycosides.

- **Detection of Cardiac Glycosides**

Keller–Killiani Test: Formation of a reddish-brown ring at the interface with bluish-green upper layer indicates cardiac glycosides.

- **Detection of Proteins and Amino Acids**

Xanthoproteic Test: Reaction with nitric acid followed by alkali produces yellow to orange coloration indicating aromatic amino acids.

- **Detection of Flavonoids**

a. Alkaline Reagent Test: Addition of NaOH or ammonia produces a dark yellow color indicating flavonoids.
b. Lead Acetate Test: Formation of a bulky white precipitate with lead acetate indicates phenolic compounds including flavonoids.

- **Detection of Phenolic Compounds**

Ferric Chloride Test: Addition of ferric chloride produces dark blue or green coloration indicating phenols.

- **Detection of Tannins**

a. NaOH Test: Addition of sodium hydroxide produces yellowish-brown coloration indicating tannins
b. $FeCl_3$ Test: Ferric chloride produces dark blue or greenish-black color indicating tannins.

- **Detection of Phytosterols**

Salkowski's Test: Reaction with chloroform and sulfuric acid produces reddish-brown coloration with green fluorescence indicating phytosterols

- **Detection of Cholesterol**

Cholesterol Test: Treatment with acetic anhydride and sulfuric acid produces color changes from red to green indicating cholesterol.

- **Detection of Terpenoids**

H_2SO_4 Test: Addition of concentrated sulfuric acid produces a dark brown precipitate indicating terpenoids.

- **Detection of Quinones**

HCl Test: Addition of concentrated hydrochloric acid produces green coloration indicating quinones.

- **Detection of Anthocyanins**

HCl Test: Heating with hydrochloric acid produces pink to crimson coloration indicating anthocyanins.

- **Detection of Carboxylic Acids**

Effervescence Test: Addition of sodium bicarbonate produces brisk effervescence indicating carboxylic acids.

- **Detection of Gums and Mucilages**

Alcohol Test: Addition of alcohol produces a cloudy white precipitate indicating gums and mucilages.

- **Detection of Resins**

Turbidity Test: Addition of water to alcoholic extract produces turbidity indicating resins.

- **Detection of Fixed Oils and Fats**

Saponification Test: Heating with alcoholic KOH followed by water produces lather indicating fixed oils and fats

TLC Methodology: [24]

Four grams of *Nilavagai Chooranam* was extracted with 40 mL distilled methanol and kept overnight with occasional shaking. The mixture was boiled in a water bath for 10 minutes, cooled and filtered. The filtrate was concentrated and the volume was made up to 10 mL. Ten microlitres of the sample solution was applied on E. Merck aluminium TLC plates pre-coated with silica gel 60 F254 using a CAMAG automatic sample applicator. The plate was developed using Toluene:Ethyl acetate:Formic acid (8.0:2.0:0.01) as mobile phase up to a distance of 80 mm. After development, the plate was dried and visualized under UV light at 254 nm and 366 nm using CAMAG TLC Visualizer. The plate was then dipped in vanillin–sulphuric acid reagent and heated at 105°C until coloured spots appeared. Finally, the plate was scanned using CAMAG TLC Scanner, the tracks were integrated and the fingerprint profile was recorded.

HPTLC Finger Print of *Nilavagai Chooranam* (Figure 3-11)

The TLC plate was developed using Toluene:Ethyl acetate:Formic acid (8.0:2.0:0.01) as mobile phase. After development, the plate was dried in air and the fingerprint profile along with densitometric chromatogram of *Nilavagai Chooranam* was recorded at 254 nm and 366 nm.

Microbial Contamination (Table 9)

Microbial contamination is strictly evaluated because the contamination of herbal drugs by microorganisms (such as bacteria and fungi) not only causes bio-disintegration but also significantly brings down the potency and therapeutic efficacy of the drugs. Minimizing moisture and microbial load is essential because excess contamination encourages the deterioration of the formulation through hydrolysis, whereas maintaining sterility ensures the product's quality, genuineness, and overall safety for patient consumption. [18]

Aflatoxins (Table 10)

Aflatoxins are highly dangerous and toxic fungal secondary metabolites produced by molds such as Aspergillus flavus, Aspergillus parasiticus, and Aspergillus nomius. This screening is strictly conducted because these compounds are highly toxic, carcinogenic, mutagenic, teratogenic, and hepatotoxic, making it crucial to ensure their absence or strictly limit their presence in herbal medicines to guarantee patient safety.AflaTest is a quantitative method for the detection of aflatoxin in B1, B2, G1, G2, M1, and M2. Five grams of *Nilavagai Chooranam* was mixed with 0.4 g sodium chloride and extracted using methanol:2% Tween 20/phosphate buffer (60:40 v/v). The mixture was vortexed for 3 minutes and filtered through fluted filter paper. Ten millilitres of filtrate was diluted with 20 mL purified water, vortexed for 1 minute and filtered through a pre-wet glass microfiber filter (1.5 μm). Ten millilitres of the diluted extract was passed through the AflaTest WB column at a flow rate of 1–2 drops/second. The column was washed with 10 mL of 2% Tween 20 followed by 10 mL purified water twice. Aflatoxins were eluted with 1 mL HPLC-grade methanol at a flow rate of 1 drop/second and collected in a sterile VICAM cuvette. One millilitre of AflaTest Developer was added and mixed well. The cuvette was immediately placed in the VICAM Series 4EX fluorometer and the aflatoxin concentration was recorded after 60 seconds. [14], [37]

DISCUSSION

The comprehensive Characterization of *Nilavagai Chooranam* yielded a robust dataset across multiple pharmacognostical, physicochemical, phytochemical, and microbiological parameters, confirming the high quality and safety of the formulation. The preliminary organoleptic and macroscopic characterization is fundamental for assessing the physical attributes and genuine nature of the crude drug mixture.The formulation presented as a fine, solid powder with a soft texture and a characteristic greenish-brown appearance. The aromatic odour strongly indicates the preservation of vital volatile principles, likely contributed by the essential oils of *Syzygium aromaticum*, *Elettaria cardamomum*, and *Cinnamomum verum*. Crucially, the macroscopic evaluation confirmed the complete absence of foreign organic or inorganic matter, which serves as a primary indicator of stringent raw material

selection and adherence to the classical purification protocols. Following organoleptic assessment, rigorous physicochemical profiling was conducted to establish quantitative markers for purity and stability. The Loss on Drying (LOD) at 105°C, a precise measure of moisture and volatile content, was remarkably low at 2.187%. Establishing a low Loss on Drying (LOD) value of 2.187% is critical for the chemical stability and long-term shelf life of *Nilavagai Chooranam* . Excess moisture in herbal powders rapidly accelerates the enzymatic hydrolysis of vital glycosides (such as the sennosides in Cassia senna) and creates a highly favourable microenvironment for the rapid proliferation of pathogenic bacteria and fungi. By restricting moisture content, the drug's therapeutic potency is preserved from bio-disintegration.

The Total Ash value, which represents the entire physiological and non-physiological inorganic residue remaining after incineration at high temperatures, was recorded at 6.9%. The Acid-Insoluble Ash, a highly specific sub-fraction of total ash that fails to dissolve in hydrochloric acid, was exceptionally low at 0.18%. The evaluation of ash values is equally paramount for determining purity. The Total Ash value of 6.9% reflects a normal, naturally occurring physiological mineral profile, entirely expected from a formulation containing 20 diverse botanical and mineral entities, including *Indhuppu* (Rock Salt). More importantly, the Acid-Insoluble Ash value of 0.18% indicates the absence of exogenous terrestrial contaminants such as soil, sand, and non-physiological silica. This low value acts as direct empirical proof that the stringent, labor-intensive classical washing and purification (Suddhi) were carried out as per protocol. The pH of the 5% aqueous extract was determined potentiometrically to be 5.8, indicating a mildly acidic nature. The detection of a formulation pH of 5.8 holds profound implications for gastrointestinal therapeutics. The gastrointestinal tract operates across a dynamic pH gradient that dictates the ionization, dissolution, and systemic absorption of all orally administered drugs. A mildly acidic pH of 5.8 mirrors the physiological environment of the proximal duodenum, ensuring the stability of weak basic alkaloids and acidic polyphenols present in the drug matrix.[25] Furthermore, highly alkaline or highly acidic herbal formulations frequently exacerbate mucosal irritation. By presenting a biocompatible pH, *Nilavagai Chooranam* ensures optimal gastrointestinal tolerance, preventing the aggravation of pre-existing micro-tears in the delicate rectal ampulla.

Furthermore, the solubility and extraction profiles were analyzed to determine the thermodynamic distribution of active constituents. The formulation proved soluble in both water and HCl. The bulk density, a critical physical parameter for assessing powder flow, compressibility, and packaging, was calculated at 0.9 g/cm³.The extractive values revealed that the water-soluble fraction (39.51%) was significantly higher than the alcohol-soluble fraction (11.11%), indicating a dominance of highly polar secondary metabolites. Biochemical analysis for acid and basic radicals provided insight into the ionic and mineral composition of the formulation. The analysis confirmed the presence of Chloride ions (cloudy appearance) and Ammonium ions (brown coloration) among the acid radicals, while Sulphate, Phosphate, Carbonate, Calcium, Magnesium, Mercury, and Arsenic were strictly absent. Among the basic radicals, Iron ions were present (mild red coloration), and an ash test indicated the presence of Sodium (yellow flame), whereas Zinc was absent. Quantitative heavy metal analysis such as ICP-MS/AAS was not performed in this study.

High-Performance Thin Layer Chromatography (HPTLC) was executed using a sophisticated mobile phase consisting of Toluene : Ethyl acetate : Formic acid (8.0 : 2.0 : 0.01). The formulation was scanned extensively at 254 nm (absorbance mode) and 366 nm (fluorescence mode) and 520 nm (absorbance mode) mapping discrete Rf values and generating densitometric chromatograms. Derivatization with a vanillin-sulphuric acid reagent followed by thermal activation successfully visualized complex-colored spots representing hidden functional groups. The dominant peaks likely correspond to anthraquinone-derived compounds (*Cassia senna*). The HPTLC densitometric chromatograms serve as a reproducible chromatographic fingerprint for identity verification. By calculating distinct Retention Factor (Rf) values and integrating peak areas across multiple wavelengths, a unique pattern is established for *Nilavagai Chooranam* . This chromatographic mapping is indispensable for regulatory quality assurance, allowing future analysts to instantly detect batch-to-batch variations, the exhaustion of active ingredients, or the fraudulent substitution of expensive raw materials.Finally, the absence of detectable arsenic and mercury ions in biochemical analysis, combined with microbial counts within permissible limits and aflatoxin levels(< 5µg/kg) below AYUSH

thresholds, indicates a satisfactory preliminary safety profileand preventing any secondary hepatobiliary or systemic toxicity. Finally, stringent safety parameters were evaluated to rule out biological contamination and mycotoxins. The Total Bacterial Count (2×10^4 cfu/g) and Total Fungal Count (< 2 cfu/g) were strictly within regulatory safety thresholds. Crucially, all specific pathogenic enterobacteria were completely absent. The evaluation of Aflatoxins (B1+B2+G1+G2) via the Vicam fluorometer method detected a negligible quantity of 2.1 ppb, confirming safety within AYUSH regulatory limitsof the polyherbal matrix.[26]

The profound therapeutic efficacy of *Nilavagai Chooranam* in successfully resolving *Malakkattu* (chronic constipation) and the wide spectrum of *Moola Noygal* (anorectal diseases) is driven entirely by the synergistic poly-pharmacology of its diverse biochemical constituents. Rather than relying on a single, isolated synthetic molecule, this classical Siddha formulation employs a complex, highly targeted cascade of active principles to simultaneously address the multifactorial etiology of hemorrhoids: impaired colonic motility, severe vascular inflammation, mucosal ulceration, and debilitating sphincter pain. [27] Chronic constipation is the primary pathogenic factor in hemorrhoidal disease, leading to excessive straining, anal cushion damage, and venous prolapse; this is effectively managed by *Cassia senna* (Nilavagai), a stimulant laxative rich in anthraquinone glycosides (sennosides A–D) [28]. These glycosides are converted by gut microbiota into active rhein anthrones, which stimulate chloride secretion, inhibit water absorption, and induce strong peristalsis, facilitating bowel evacuation without straining [29]. This action is synergistically enhanced by *Operculina turpethum* (Sivadhai), containing turpethin, which exerts hydragogue cathartic effects by increasing luminal water content, softening stools, and promoting easy defecation while also offering cytoprotective and anti-ulcer benefits to maintain mucosal integrity [30], [31].

Inflammation and sphincter spasm, key features of Ratha Moolam, are addressed by *Picrorhiza scrophulariiflora* / *P. kurroa* (Kadugurogini), which contains iridoid glycosides (picroside I and II) that inhibit NF-κB signaling and suppress pro-inflammatory cytokine production at the site of vascular congestion [32]. Analgesic and antispasmodic effects are supported by *Zingiber officinale* (Sukku) and *Piper nigrum* (Milagu); 6-gingerol inhibits COX and LOX pathways, reducing prostaglandin-mediated pain, while piperine enhances bioavailability of co-administered drugs and relieves tenesmus and sphincter spasm [33], [34]. Preliminary phytochemical screening of alcohol and hydro-alcoholic extracts confirmed the presence of carbohydrates, reducing sugars, flavonoids, phenolics, tannins, and phytosterols, with alkaloids detected in hydro-alcoholic extracts, while glycosides, proteins, cholesterol, terpenoids, quinones, anthocyanins, and fixed oils were absent. Flavonoids and tannins play a central role in structural healing and hemostasis. Flavonoids such as diosmin, rutin, hesperidin, and quercetin exhibit phlebotonic effects by enhancing venous tone via prolongation of noradrenaline action, reducing venous stasis, decreasing capillary permeability, and improving lymphatic drainage, thereby alleviating edema in hemorrhoidal conditions [26], [35]. Tannins from *Terminalia chebula* and *Terminalia bellerica* act as potent astringents, precipitating mucosal proteins to form a protective layer that seals bleeding vessels, reduces microbial irritation, and accelerates wound healing [36]. The integrated pharmacological actions—anthraquinones relieving constipation, flavonoids restoring venous tone, iridoid glycosides suppressing inflammation, and tannins providing hemostasis—collectively validate the therapeutic efficacy of this polyherbal formulation in hemorrhoidal management, offering a comprehensive approach superior to single-target interventions [37].

CONCLUSION

In conclusion, the comprehensive pharmacognostical, physicochemical, and microbiological characterization of the Siddha polyherbal formulation *Nilavagai Chooranam* successfully establishes its high purity, chemical stability, and strict compliance with modern regulatory and pharmacopoeial guidelines. The analytical validation of its complex 20-ingredient matrix- rich in active secondary metabolites like flavonoids, tannins, and anthraquinone glycosides—provides a robust scientific rationale for its classical therapeutic indication in treating multifactorial anorectal diseases (*Moola noygal*) and chronic constipation (*Malakkattu*). By demonstrating a significant synergistic capacity that encompasses laxative, anti-inflammatory, analgesic, and venotonic activities, the formulation offers a holistic,

effective, and safe alternative to conventional synthetic treatments. Moving forward, advanced *in vivo* pharmacological modeling, molecular docking studies, and rigorous randomized controlled clinical trials are highly warranted to definitively map its molecular mechanisms and facilitate the integration of this ancient Siddha remedy into evidence-based, global clinical practice.

Limitations and Recommendations

While the physicochemical and phytochemical characterization of *Nilavagai Chooranam* establishes a reliable and reproducible quality control framework in line with PLIM and WHO guidelines, it also highlights important directions for future research. Advanced parameters like heavy metal analysis and pesticide residue tests can be done. Batch to batch variability also need to be tested for standardization. The next step should involve in vivo pharmacological studies using validated animal models, such as hemorrhoid induction and gastrointestinal transit assays, to quantify its anti-inflammatory, venotonic, and prokinetic effects. This can be complemented by molecular docking and network pharmacology approaches to better understand interactions between key phytoconstituents

ABSTRACT

The classification of lung cancer using images obtained from the chest X-ray with high accuracy is important for the early detection of lung cancer and help clinicians make clinical decisions. In this study, a Robust Multi-Scale Convolutional Feature Encoder (R-MSCFE) is proposed. The proposed network architecture can gather high, medium, and low-level features through parallel branches utilizing conventional and dilated convolutions. Multi-level features are combined through feature concatenation and further refined through channel alignment and attention-based re-weighting for pathology related regions. Residual feature enhancement is used for retaining the original information of the feature and stabilizing during the training process. The model performance is analyzed on an open access Kaggle lung cancer dataset for chest X-rays. Experimental assessment validates exceptional diagnostic efficacy, attaining an accuracy of 99.86%, precision of 100%, recall of 99.71%, and an F1-score of 99.86%. The findings demonstrate that the suggested R-MSCFE framework offers a dependable and effective approach for automated lung cancer screening via chest X-ray imaging

Keywords: Robust Multi-Scale Feature Encoder, Lung Cancer Classification, Chest X-Ray Imaging, Deep Learning, Convolutional Neural Network

INTRODUCTION

Recently, many deep learning architectures for classifying lung cancers using chest X-ray imaging were developed. Hybrid Quantum-Classical CNN architectures used quantum convolutional processes for extracting features, and NASNet and Vision Transformer frameworks adopted a combination of local convolutional processes and global dependency learning. Multi-stage deep learning frameworks used a series of pretrained models for classification refinement. In contrast, DeepLungNet incorporated stacking of CNN architectures with global average pooling to avoid overfitting. LungMaxViT used transformer attention architecture with explainable AI to facilitate lung disease classification. Even though all those models successfully performed the lung cancer classification task, many of them are known to exhibit high computational complexity, dependence on transformer components, multi-stage operations, and inability to classify multiple scales of lung pathologies concurrently. Some techniques are highly dependent on manual enhancement processes and ensembles that limit their computational performance and real-world applications. To address all these shortcomings, a robust framework based on parallel convolutional branches, adaptive feature fusion, channel attention, and residual reinforcement is developed, referred to as Robust Multi-Scale Convolutional Feature Encoder (R-MSCFE). The study proposes Robust Multi-Scale Convolutional Feature Encoder (R-MSCFE) which can be used to diagnose lung cancers using chest X-ray images. The encoder consists of a series of parallel convolution pathways with adaptive feature fusion to capture information in fine, medium and coarse scales. R-MSCFE encoder incorporates local and global information such as textures and contextual information. As compared to conventional CNN which uses sequential convolutions, the proposed model is more effective in enhancing discriminatory learning due to the incorporation of multiple scales within the network.

Related Works

Considering limitations associated with the currently available methods used for lung cancer screening and increased demand for intelligent assistance in diagnosis, this research has been conducted. Chest X-ray images are easily accessible but not as accurate as computerized tomography in identifying early lung cancers. Small nodules, blurry lung opacity, and asymmetrical masses in lung tissue can sometimes go unnoticed. Radiological diagnosis tends to fail due to low number or poor visibility of disease indicators. Deep learning allows automation of identification and classification of such tumors. There are different shapes and sizes of abnormalities in the development of lung cancer. Sometimes, small or big abnormality can be missed by single convolutional layer with a fixed receptive field. Consequently, multi-scale feature learning becomes necessary. Small sample size and class imbalance lead to overfitting and reduce generalization capability of a model. R-MSCFE architecture proposed in this paper provides scale invariant feature learning that solves these problems. It allows capturing lung features through a combination of different convolutional layers having distinct receptive fields. Attention guided refinement of extracted features allows highlighting discriminative patterns. Such architecture allows efficient classification of lung cancer.

.

Hybrid quantum-classical CNN was used for multiclass lung X-ray image classification in [1]. Feature maps are flattened and processed through a quantum convolutional layer using qubits with Rotation (RX/RY) and Pauli (X/Y/Z) gates. Dense layers with dropout and Soft Max perform final prediction. A NASNet and vision transformer-based deep learning architecture with mix processing for precise lung disease identification was shown in [2]. A NASNet–Vision Transformer hybrid model was used, where NASNet extracts local convolutional features using normal and reduction cells, while ViT captures global dependencies through patch embedding, positional encoding, and multi-head self-attention. A Mix Processing pipeline combining wavelet decomposition, CLAHE, Fourier filtering, and morphological operations improves image quality. NASNet and ViT features are fused using element-wise multiplication, followed by an MLP classifier. Comprehensive lung disease classification from X-ray images using multi-stage deep learning was studied in [3]. A multi-stage deep learning tool chain was implemented, where classification is refined through sequential decision stages. Transfer learning is applied using ResNet-50, DarkNet-53, EfficientNet-B0, ResNet-101, and DenseNet-201. Each stage selects an optimal pretrained model with tuned hyperparameters. DeepLungNet an advanced deep learning architecture having global average pooling, was discussed for classification of lung cancer precisely in [4]. Deep LungNet is an enhanced CNN model with stacked

convolutional layers and ReLU activation for hierarchical feature learning, followed by max-pooling for spatial reduction. A Global Average Pooling layer replaces fully connected layers to reduce parameters and mitigate overfitting.

Machine learning on X-rays predicts lung illnesses were detailed in [5]. The introduction of ResNet-D as a ResNet extension is based on its capacity to minimize information loss during down-sampling operations. As compared to strides in residual connections, ResNet-D employs average pooling in skip connections coupled with 1×1 convolution for channel compatibility. Such design preserves spatial information and facilitates robust feature propagation for classification tasks. Explainable hybrid transformers for chest X-ray lung disease multi-classification is proposed in [6]. The framework, called LungMaxViT, uses CNN-based feature extraction techniques, where a Squeeze-and-Excitation block enhances the process. Then, a transformer component inspired by Max ViT is applied, which incorporates MBConv and multi-axis block and grid attentions [7]. CLAHE is used for improving lung image clarity, whereas denoising is used for contrast improvement and explainable localization of attention through Grad-CAM. An anatomically augmented and clinically validated deep learning features and KL divergence lung anomalies classification pipeline is presented in [8]. An anatomically augmented and contrast and color mapped deep learning framework, known as ASCE-based framework, enhances lungs' representation through feature extraction using ResNet50 followed by KL divergence for lung anomalies' quantification. CNN based prognosis system incorporates data cleansing, feature engineering and min-max normalization. Hierarchical features are extracted using convolution and pooling layers, whereas fully connected layers are used for performing prognosis at severity levels. Moreover, sophisticated architectures of CNN models like ResNet and DenseNet are also being studied.

A deep learning ensemble technique for classifying lung diseases using chest X-rays has been proposed in [9]. A combined CNN-GRU model is used, whereby the CNN layers identify spatial textures and opacities via convolutional and pooling operations. The resultant feature maps are sent to a GRU layer to obtain the sequential relationship between learned features. SoftMax activation functions in dense layers produce the ultimate classification of multiple classes. Artificial intelligence techniques for detecting pulmonary disease in chest X-ray and chest multi-slice CT images have been reviewed in [10]. The comparison involves three network types – CNN, DNN, and ResNet50. Preprocessing entails noise reduction, image resizing, and normalization before training and testing. ResNet50 boosts classification with the aid of residual learning to increase feature extraction capacity on both X-ray and CT images [11]. The transfer learning approach involves the tuning of the pre-trained models like VGG-16, DenseNet-121, and DenseNet-201. The output layer is customized with layers such as AveragePooling2D, Flatten, Dense, Dropout, and SoftMax. Dense connection in DenseNet allows for the reusing of features and stable backpropagation for efficient multiclass classification. Bagging-based Deep Learning Ensemble for Improving Multi-class Lung Disease Classification was explained using five architectures in [12]. The bagging-based ensemble architecture involves the tuning of several pre-trained models like ResNet50, VGG16, VGG19, MobileNetV2, and DenseNet201. These models are trained individually, and then their results are combined with ensemble techniques like voting.

The optimization of deep learning models for predicting lung cancer through chest x-rays was described in [13]. The architecture of the risk prediction model of a neural network consists of chest X-ray pre-processing and clinical feature representation. A multilayer neural network predicts the probability of lung cancer risk. The probability is optimized using model optimization and ROC curves. The predicted probability is classified according to the established categories of lung cancer risk. The development of an explainable artificial intelligence system for lung diseases classification based on chest X-rays with transfer learning was introduced in [14]. The fine-tuning process is applied to DenseNet201 transfer learning model for multi-class classification tasks. Image enhancement includes denoising autoencoder, CLAHE, and gamma correction. Disease regions are explained using Grad-CAM, Grad-CAM++, SHAP, and LIME methods were presented in [15]. The transfer learning model is built based on MobileNetV1, whereby deep features will be extracted and a customized dense classifier with a sigmoid activation function will be used for predicting the labels in multiple labels. Data augmentation and image sharpening help improve data quality. The model uses a DCGAN module to generate new X-ray data, which helps in minimizing the

issue of class imbalance. The comprehensive background of CT and X-ray images for rapid and accurate identification of abnormal lungs using explainable AI is presented in [16]. CTXNET uses a Compact Convolutional Transformer involving convolutional tokenization together with self-attention mechanism and sequence pooling.

Lung disease images based on explainable-AI was explained in [17]. A literature-based survey presents the conventional ML methods that employ texture features extracted manually by applying algorithms like SVM and KNN alongside deep learning models including CNN architecture and pre-trained models such as VGG, ResNet, DenseNet, Inception, and Xception. It covers the use of ensemble and explainability approaches such as Grad-CAM, LIME, SHAP, saliency maps, and integrated gradients. Deep learning model with transfer learning and customized CNN architecture for the task of lung disease classification is reported in [18]. The transfer learning process is carried out using MobileNetV2 with all layers fine-tuned. Here, a customized model called MobileNet-Lung with Squeeze-and-Excitation mechanism added to the convolution layer followed by a better classifier is proposed. Lung diseases classification in chest x-rays based on transfer learning and hype rparameter customization is briefly discussed in [19]. CovEnViT includes a convolutional encoding component made up of two 3×3 convolutions with ReLU, which facilitates the learning of local features before patch embedding. The encoder blocks in the transformer are composed of multi-head self-attention that learns global interactions, and the MLP head carries out the final classification task. Improved lung cancer classification using deep learning techniques and CNNs is well explained in [20]. Three CNN networks have been designed and trained via grayscale scaling and feature extraction. Oversampling via SMOTE helps address data imbalance issues.

METHODS AND MATERIALS

This describes the completely suggested system for lung cancer classification using chest X-ray images. The framework is designed to learn robust discriminative representations by extracting features at multiple spatial scales and integrating them through attention-guided fusion. The overall goal of the suggested system is to accurately classify chest X-ray images into lung cancer and non-cancer classes by capturing both fine-grained lesion patterns and coarse global abnormalities. The suggested system consists of four major phases such as (i) image preprocessing, (ii) robust multi-scale convolutional feature encoding, (iii) attention-based feature refinement and residual reinforcement, and (iv) classification and performance evaluation. An input chest X-ray feature map is processed in three parallel processes is shown in Figure 1. Through 3x3 convolution, batch normalization, and ReLU, fine-scale texture features are created, revealing small intensity fluctuations. The 5x5 convolutional medium-scale feature route captures regional lung patterns with mid-level structural characteristics. The coarse-scale feature route (dilated 3x3 convolution) captures global diseased areas' extensive background characteristics. Concatenating these results creates a multi-scale description. A 1x1 convolution aligns channel dimensions, while channel attention reweighting highlights pathology-relevant characteristics. Finally, residual feature reinforcement incorporates input data to create a strong multi-scale feature representation for classification.

Input Image Acquisition and Preprocessing

The image data of chest x-rays are usually prone to changes in illumination, noise, poor contrast, and resolution. Such defects might impact feature extraction and lower the accuracy rate of classification. Input to the proposed framework is a chest X-ray image to classify lung cancer. Let us denote the obtained radiography image:

$$X \in \mathbb{R}^{M \times N} \qquad (1)$$

where M and N the chest X-ray image denoted by the spatial dimensions. Pre processing activities are done to increase the picture consistency and feature learning capacity before classification, since the radiographic images are acquired from varied imaging settings.

Image Resizing

A fixed resolution was adopted for each resized image for uniformity and compatibility with the convolutional encoder.

$$X_s = \psi(X, p, q) \quad (2)$$

where $\psi(.)$ The spatial transformation function is denoted by, and p and q are the specified picture size utilised throughout the learning phase. This method lets to extract features uniformly throughout all the chest radiographs.

Intensity Normalization Pixel Distribution Adjustment

Over the standardised image, pixel intensity modification is conducted to stabilise feature propagation and enhance convergence during training. The converted intensity is expressed as:

$$X_t(u, v) = \frac{X_s(u,v)}{\lambda} \quad (3)$$

where $X_t(u, v)$ represents the standardized pixel value at spatial position (u, v), and λ denotes the scaling factor used to normalize the intensity distribution. This process reduces intensity variations and improves feature consistency across chest X-ray samples.

Radiographic Enhancement

Further image enhancement procedures are performed on the converted image for improving the visibility of lung tissues, nodular structures, and aberrant opacity areas. Below is the improved depiction of the image:

$$X_e = \Omega(X_t) \quad (4)$$

where Ω(.) refers to the radiography enhancement function used for optimal distribution of contrast and highlighting the pathologically related areas. The enhanced image is then fed into the proposed multi-scale convolutional feature encoder for lung cancer discrimination. The proposed model further applies the processed chest radiograph image to several convolution layers having varied receptive fields. The small-sized convolution filters can detect local variations in edges and textures, whereas larger receptive fields can learn global information regarding lung structure and tissue distribution. The 5x5 convolution branch extracts medium-scale characteristics, which include regional lung architecture and abnormal opacity patterns. Dilated 3x3 convolution collects contextual characteristics for vast diseased areas. Each branch pools to create scale-specific summarized feature maps. Features from these outputs are fused to provide a multi-scale feature representation including fine, medium, and coarse information. Finally, the lung cancer classification module uses this unified model to predict normal, benign, or malignant outcomes.

Robust Multi-Scale Convolutional Feature Encoder (R-MSCFE)

The key novelty of the suggested framework is the Robust Multi-Scale Convolutional Feature Encoder (R-MSCFE), which extracts features using parallel convolutional branches operating at different receptive fields. Lung cancer patterns in chest X-rays may appear as small nodules, medium-size irregular opacities, or large abnormal lung masses. A single convolution scale may fail to capture all variations. Therefore, multi-scale convolution is introduced. Let the pre-processed input image be:

$$X = I_e \quad (5)$$

Fine-Scale Feature Extraction Branch

Fine-scale features capture small texture variations and edge information. A 3×3 convolution is used:

$$F_1 = \sigma(BN(W_1 * X + b_1)) \quad (6)$$

where W_1 represents the convolution kernel of size 3×3, b_1 is bias, $*$ denotes convolution operation, $BN(\cdot)$ is batch normalization, and $\sigma(\cdot)$ denotes ReLU activation.

Medium-Scale Feature Extraction Branch

Medium-scale features capture larger structural lung patterns. A 5×5 convolution is applied:

$$F_2 = \sigma(BN(W_2 * X + b_2)) \quad (7)$$

where W_2 is a 5×5 kernel.

Coarse-Scale Feature Extraction Branch

Coarse-scale features capture global lung context and large abnormal regions. A dilated convolution is applied:

$$F_3 = \sigma(BN(W_3 *_d X + b_3)) \quad (8)$$

where $*_d$ denotes dilated convolution with dilation rate d, enabling a larger receptive field without increasing parameters.

Multi-Scale Feature Fusion

After extracting features from three branches, the next step is featuring fusion to combine fine, medium, and coarse-scale information. The outputs F_1, F_2, and $F_3$are concatenated along the channel dimension.

$$F_c = Concat(F_1, F_2, F_3) \quad (9)$$

The concatenated feature map F_c contains complementary representations from different receptive fields.

Channel Alignment using 1×1 Convolution

The concatenated feature map has increased channel size, which may increase computational complexity. Therefore, a 1×1 convolution is applied for channel reduction and alignment:

$$F_a = \sigma(BN(W_a * F_c + b_a)) \quad (10)$$

where W_a is a 1×1 convolution kernel. This operation reduces redundancy and ensures consistent feature embedding.

Channel Attention Reweighting

Multi-scale fusion gives many characteristics; however, all the channels are not equal in value for the classification of lung cancer. Attention reweighting is utilized to boost pathology-relevant channels.

Global Average Pooling for Attention

A global average pooling operation is applied:

$$z_k = \frac{1}{H_f W_f} \sum_{x=1}^{H_f} \sum_{y=1}^{W_f} F_a^k(x, y) \quad (11)$$

where z_k represents the global descriptor of channel k, and H_f, W_f are feature map dimensions.

Attention Weight Computation

The channel weights are computed using a gating function:

$$s = \delta(W_2^{att}(\sigma(W_1^{att} z))) \quad (12)$$

where W_1^{att} and W_2^{att} are learnable weights, σ is ReLU, and δ is sigmoid activation.

Feature Reweighting

The final attention-enhanced feature map is obtained as:

$$F_{att}^k = s_k \cdot F_a^k \quad (13)$$

This ensures important lung abnormality patterns dominate the representation.

Residual Feature Reinforcement

To increase feature stability and prevent any spatial information loss during feature extraction through deep layers, residual learning technique is employed. Feature representation after improvement is obtained by fusing attention-augmented features with baseline feature representation. This can be expressed as:

$$R_f = \phi(A_f, B_f) \quad (14)$$

where A_f represents the attention-refined feature representation, B_f denotes the aligned baseline feature map, and $\Phi(.)$indicates the residual fusion operation. This process aids in gradient propagation and maintains critical structural lung information throughout training.

Classification Module

Then, the robust multi-scale feature representation is generated, and the retrieved features are translated into compact discriminative vectors for lung cancer classification.

Global Feature Aggregation

First, spatial feature representations are pooled by global pooling procedures to form a compact descriptor:

$$Z_g = \wedge (R_f) \quad (15)$$

where $\Lambda(.)$ denotes the global aggregation transformation applied to the reinforced feature representation R_f. This operation reduces feature dimensionality while preserving discriminative information.

Dense Representation Learning

Then the aggregated feature vector is mapped to higher-level discriminative representations by nonlinear mapping operations:

$$Dh=\Gamma(Zg) \quad (16)$$

where $\Gamma(.)$ represents the dense nonlinear transformation used to enhance classification-oriented feature learning. Feature regularisation is further used to increase the generalisation ability and decrease the overfitting during training as:

$$D_r = = \Psi(\mathrm{D}_h) \quad (17)$$

where $\Psi(.)$ denotes the feature regularization operation applied to the learned dense representation.

Output Prediction

Finally, the regularized feature representation is sent to the output prediction stage for lung cancer classification. The prediction representation may be stated as:

$$P_o = \Upsilon(D_r) \quad (18)$$

where $\Upsilon(.)$ corresponds to the last classification transformation that produces the prediction probabilities of lung cancer classes. Normalised probability distribution is created across all classes for multiclass lung disease classification:

$$Q_i = \frac{\exp (T_i)}{\sum_{k=1}^{K} \exp (T_k)} \quad (19)$$

where K denotes the total number of lung disease categories and T_i represents the classification activation score corresponding to the i^{th} category.

Loss Function Optimization

In the proposed framework, the optimum trainable parameters are learned by minimizing the classification loss between the anticipated and real categories.

Binary Optimization Objective

For binary lung cancer classification, the optimization objective is expressed as:

$$\mathcal{J}_b = \Omega(\mathrm{Y}, \mathrm{P}) \quad (20)$$

where Y denotes the actual class representation and P represents the predicted classification probability.

Categorical Cross Entropy

For multi-category classification problems, the optimization objective is represented as:

$$\mathcal{J}_m = \sum_{i=1}^{K} (Y_i, Q_i) \quad (21)$$

Training Strategy

The trainable parameters of the proposed framework are optimized repeatedly using gradient-based learning techniques. The parameter refinement operation may be described as:

$$\mathbb{E}_{t+1} = \mathbb{E}_t - \rho \nabla \mathcal{J} \quad (22)$$

where ρ denotes the adaptive learning coefficient, Ξ represents trainable model parameters, and $\nabla \mathcal{J}$ denotes the optimization gradient. To further stabilize the optimization and speed up the convergence, the adaptive moment estimation is used using the first order and second-order gradient accumulation operations:

$$M_t = \alpha M_{t-1} + (1 - \alpha) G_t \quad (23)$$

$$V_t = \beta V_{t-1} + (1 - \beta) G_t^2 \quad (24)$$

where G_t denotes the optimization gradient, while M_t and V_t represent adaptive moment estimations used for stable parameter optimization during network training.

Overall Workflow Summary

The architecture of the Multi-Scale Convolutional Network for lung cancer classification starts with data acquisition and preprocessing steps such as resizing, normalization, and radiography enhancement to ensure the image is of high quality and consistent features. Following this, the enhanced chest x-rays are fed into various parallel convolutional modules working on distinct receptive fields for extracting fine, medium, and coarse representations of the lung. Multiscale feature fusion helps merge the features in one single feature space, where channel attention and residual enhancement help learn more discriminating features while preserving spatial information. The resultant robust representation of the features is then used in global feature extraction and classification layers for lung cancer category prediction.

Advantages of the Suggested System

The proposed multi-scale convolutional network has various benefits for automated lung cancer classification from chest X-ray images. The multi-scale convolutional design can capture both localized texture defects and global contextual lung structures, which improves the feature representation capabilities compared to the traditional single-scale CNN models. Parallel convolutional branches improve the identification of tiny nodules and irregular opacities and big aberrant areas concurrently. An attention-guided feature refinement is included to highlight the pathology-relevant areas and reduce the unnecessary background information. Residual reinforcement facilitates gradient propagation and maintains the original feature representations, leading to robust network optimization and lower performance degradation. Moreover, the suggested framework has reduced computational cost compared to the transformer-heavy designs, which makes it effective for clinical deployment and real-time lung cancer classification applications. The Robust Multi-Scale Convolutional Feature Encoder (R-MSCFE) offers a robust architecture for lung cancer classification from chest X-ray images. The proposed method efficiently captures discriminative lung cancer features at various spatial resolutions via the fusing of parallel multi-scale convolutions, feature fusion, attention refinement and residual reinforcement. The concept enhances the reliability of classification while preserving computational efficiency, which is suited for real-time clinical screening applications.

Evaluation Metrics

This dataset is a collection of chest X-ray images for lung cancer research and classification. It is organised in directories according to various lung health issues, enabling supervised learning for deep learning models [21].

Image categories:

- Lung cancer cases
- Normal (no cancer) cases (Exact class labels and counts are based on the dataset's directory structure.)

Image format & preprocessing readiness:

- Images are typically in standard image formats (e.g., JPEG/PNG).
- The dataset is ready for resizing, normalization, augmentation, and deep model input pipelines.

Data augmentation was done with training of 5216 images, validation of 16 images and testing images of 624 images which total of 5856 images. To evaluate the suggested system, standard classification performance metrics are computed using True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN).

Accuracy

Accuracy measures overall correct classification:

$$\text{Accuracy} = \frac{\text{TP}+\text{TN}}{\text{TP}+\text{TN}+\text{FP}+\text{FN}} \quad (26)$$

Precision

Precision evaluates the correctness of positive predictions:

$$\text{Precision} = \frac{\text{TP}}{\text{TP}+\text{FP}} \quad (27)$$

Recall (Sensitivity)

Recall measures the ability to identify true cancer cases:

$$\text{Recall} = \frac{\text{TP}}{\text{TP}+\text{FN}} \quad (28)$$

F1-Score

F1-score is the harmonic mean of precision and recall:

$$\text{F1} = \frac{2\times\text{Precision}\ \times\text{Recall}}{\text{Precision}\ +\text{Recall}} \quad (29)$$

Specificity

Specificity measures true negative recognition:

$$\text{Specificity} = \frac{\text{TN}}{\text{TN}+\text{FP}} \quad (30)$$

Figure 3 illustrates a heat map of classification outcomes between normal and cancer chest X-ray classes. The diagonal cells show higher numerical values of 346 and 347, indicating many correctly classified normal and cancer cases. Figure 4 shows chest X-ray images belonging to the normal class used for model training and evaluation. The images show clean lung zones, well defined rib structures and consistent intensity distribution without any obvious abnormality. The consistency of anatomical features across samples offers a valid reference for the learning of the normal lung characteristics, which allows the model to successfully discriminate between healthy cases and problematic ones in the classification process. Chest X-ray images of the cancer class utilized in this investigation are shown in Figure 5. These images show important anomalies such as increased lung opacity, uneven texture patterns and asymmetric intensity distributions compared to normal instances. These visual alterations relate to the pathological changes seen in lung cancer. The inter-sample visual heterogeneity highlights the need of extracting multi-scale features for accurate and robust cancer classification. The performance of multiple lung cancer classification algorithms employing accuracy, precision, recall, and F1-score is compared in Figure 6. Figure 6. Comparative Performance Analysis of Lung Cancer Classification Techniques The Hybrid CNN [1] achieves the lowest performance with 91% across all measures. NASNet-ViT [2] improves results, reaching 98.90% accuracy and 99% precision/recall. The KL divergence-based method [7] shows reduced precision and F1-score. GRU [9] provides balanced performance. The suggested MSCFE achieves the highest accuracy (99.86%), precision (100%), recall (99.71%), and F1-score (99.86%).

CONCLUSION

The proposed Robust Multi-Scale Convolutional Feature Encoder (R-MSCFE) framework was devised for enhancing classification of lung cancers using chest X-ray imaging data. The framework can extract fine-grained, medium-grained, and coarse-grained representations of the lungs via multiple convolution branches, allowing efficient learning of localized textures and abnormal areas. Adaptive multi-scale feature fusion and attention mechanism-

based channel re-weighting contribute to learning of more informative and discriminating features in terms of disease-related attributes. Residual-based feature reinforcement can maintain significant spatial representations and ensure robustness in feature learning. Experimental results have shown that our proposed approach is highly capable of lung cancer detection based on the high levels of classification accuracy, precision, recall, and F1-score. Although impressive results were obtained, several limitations exist. The proposed model has been validated on relatively small benchmarking data and would benefit from validation on large multi-center clinical databases to confirm its generalization power. It should be noted that chest X-rays have inferior ability to detect subtle abnormalities as opposed to some more sophisticated imaging techniques. Some possible areas for future work include incorporating explainable artificial intelligence, hybrid attention models, and lightweight techniques.

ABSTRACT

Mutrashmarī (urolithiasis) is classified among the ashta mahagada by Sushruta, underscoring its potential for serious morbidity. Sigrumulatwak kvatha is specifically indicated for ashmari in Ashtanga Hridayam, yet no clinical study has evaluated its efficacy to date. Varunadi kvatha has prior documented clinical evidence in urolithiasis. To study, observe, and compare the effectiveness of Varunadi kvatha and Sigrumulatwak kvatha in patients of Mutrashmarī, and to assess changes in signs, symptoms, serum calcium, and size and number of urinary calculi. A randomized, open-label, parallel-group (1:1), clinico-comparative clinical trial was conducted at the OPD of Kayachikitsa and Panchakarma Department. Two hundred patients were enrolled (100 per group). Randomization used a computer-generated sequence (block size 4); allocation concealment by serially numbered opaque sealed envelopes. Group A received Varunadi kvatha (40 ml BD) and Group B received Sigrumulatwak kvatha (40 ml BD), both with Yavakshara (125 mg), for 6 months. IEC clearance: EC/NEW/INST/2023/4029; CTRI: CTRI/2024/07/071116.

Results: Both groups showed statistically highly significant improvement ($P<0.001$) in all parameters. Group A was superior in constipation (71.20%) and stone number reduction. Group B was superior in pain (68.3%), dysuria (59.5%), weakness (69.8%), stone size reduction, and hydronephrosis resolution. No adverse effects were observed. Both Varunadi kvatha and Sigrumulatwak kvatha demonstrate significant efficacy in Mutrashmarī with no significant inter-group difference in overall outcome. Sigrumulatwak kvatha is hereby clinically validated for the first time, corroborating its classical indication in Ashtanga Hridayam. Both formulations were safe and well-tolerated.

Keywords: Mutrashmarī, Urolithiasis, Varunadi kvatha, Sigrumulatwak kvatha, Randomized clinical trial, Ayurveda

INTRODUCTION

Mutrashmarī (urolithiasis) is classified among ashta mahagada by Sushruta [1], signifying its potential for serious morbidity and mortality. Ashtanga Hridayam recommends medical management for the acute (taruna) stage and surgical management for the chronic (pravriddha) stage [2]. Urolithiasis refers to stone formation in the kidney, ureter, or urinary bladder due to supersaturation of urine with insoluble crystalline substances. Increased serum calcium promotes hypercalciuria and crystal aggregation, ultimately forming calculi [3]. The global prevalence ranges between 1–15%, with a lifetime risk of approximately 10–15% in developed countries [5]. Gujarat, with its high total dissolved salts (TDS) content in groundwater [4], carries a disproportionately high burden — approximately 30% of urinary disorder patients in this region are affected. Stone composition includes calcium oxalate (~50%), calcium phosphate (15–25%), struvite (15–30%), cystine (6–10%), and uric acid (2–10%) [6]. In Ayurveda, Mutrashmarī is a kaphapradhana tridosha disorder in which vitiation of apana vayu plays the principal pathogenic role. Causative factors include suppression of natural urges (vega dharana), irregular dietary habits, and impaired agni — all leading to sharkara formation coalescing into ashmari [7].

Varunadi kvatha, with principal ingredient varuna (Crataeva nurvala Buch.-Ham.), has documented antilithogenic, diuretic, and vatanulomana properties [8,9]. Although Sigrumulatwak kvatha is indicated for ashmari in Ashtanga Hridayam [10], no research article has documented its clinical effectiveness. The active phytoconstituents of shigru (Moringa oleifera Lam.) root bark, including moringine alkaloids, possess analgesic, anti-inflammatory, and diuretic properties [11,12]. The recurrence rate of urolithiasis is approximately 50% within 5 years without intervention [13]. Conventional agents carry side effects with prolonged use [14]. The present study was designed to fill the evidence gap by clinically comparing both formulations in Mutrashmarī.

MATERIALS AND METHODS

Study Design and Registration: This was a randomized, open-label, parallel-group, clinico-comparative clinical trial with a 1:1 allocation ratio. IEC clearances: EC/NEW/INST/2023/4029 and MAMCH/ADMN/IEC.APPROVAL/2023-24/199. CTRI Registration: CTRI/2024/07/071116. The study was conducted in accordance with the Declaration of Helsinki [15]. Written informed consent was obtained from all participants.

Sample Size: A sample size of 200 patients (100 per group) was determined a priori based on a pilot study and published literature by Krishnamurthy and Tiwari [8] reporting a 20% difference in stone size reduction. Assuming 80% power and 5% level of significance (two-tailed), with 10% dropout margin, the calculated sample size was 91 per group, rounded to 100 per group.

Randomization and Allocation Concealment: The random allocation sequence was generated by an independent statistician using computer software with simple block randomization (block size = 4). Allocation concealment was implemented using serially numbered opaque sealed envelopes. This was an open-label trial; blinding of participants and treating physicians was not feasible. Both interventions were identical in volume (40 ml), route (oral), timing (twice daily), and vehicle (Yavakshara 125 mg) to minimize performance bias.

Selection of Patients: Patients were recruited from the OPD of Kayachikitsa and Panchakarma Department from August 2023 to July 2024. Diagnosis was established based on clinical signs and symptoms, urine routine and microscopic examination, and ultrasound sonography (KUB region). Inclusion criteria: age 18–80 years; stone size up to 10 mm on USG. Exclusion criteria: severe renal colic requiring emergency intervention, severe hydronephrosis, acute renal disease, staghorn calculi, and other specified conditions.

Interventions (Table 1): Both medicines were prepared as standardized aqueous decoctions at the trial pharmacy under expert supervision. Varunadi kvatha (Group A) contains Varuna (Crataeva nurvala), Pashanabheda (Bergenia ligulata), Gokshura (Tribulus terrestris), and Punarnava (Boerhavia diffusa) as per Ashtanga Hridayam Chikitsasthana. Sigrumulatwak kvatha (Group B) contains Shigru root bark (Moringa oleifera) as principal ingredient with Yavakshara (125 mg) as prakshepa dravya in both groups.

Outcome Measures: Primary outcome: reduction in stone size (mm) on USG-KUB from baseline to end of 6-month treatment. Secondary outcomes: changes in subjective symptom scores (pain, burning micturition, dysuria, frequency, nausea, vomiting, weakness, constipation) assessed monthly using 0–3 graded scales (Tables 2–4); reduction in stone number; hydronephrosis resolution; serum calcium; CBC and urine routine/microscopy.

Statistical Methods: Paired t-test (within-group, pre–post comparison) and unpaired two-tailed t-test with unequal variance (between-group comparison). $P<0.05$ was considered statistically significant. Data are presented as mean ± SD with 95% confidence intervals. Analysis was performed on the per-protocol population.

OBSERVATIONS AND RESULTS

Participant Flow: A total of 243 patients were screened. Of these, 43 were excluded (18 did not meet inclusion criteria; 16 declined to participate; 9 had stone size >10 mm on USG). The remaining 200 patients were randomized — 100 to Group A and 100 to Group B. All 200 completed the 6-month treatment period and were included in the final per-protocol analysis. There were no dropouts, withdrawals, or losses to follow-up. [A CONSORT flow diagram is submitted as a separate figure file.]

Baseline Characteristics (Table 5): Baseline demographic and clinical characteristics were comparable between the two groups (all $P>0.05$), confirming successful randomization.

Effect on Primary Outcome — Stone Size: Group B showed significantly greater reduction in stone size on USG-KUB (mean reduction 3.1 ± 0.8 mm, 95% CI: 2.9–3.3 mm) compared to Group A (mean reduction 2.7 ± 0.7 mm, 95% CI: 2.5–2.9 mm), with a statistically significant between-group difference ($P<0.05$).

Effect on Primary Symptoms (Table 6): The reduction in mean pain score showed 59.6% relief in Group A and 68.3% relief in Group B ($P<0.001$). Sadahamutraprvritti showed 58.9% relief in Group A and 62.8% in Group B ($P<0.05$). Mutrakricchhra showed 60% relief in Group A and 59.5% in Group B ($P<0.05$). Frequency of micturition: 57.8% relief in Group A and 45.1% in Group B ($P<0.05$).

Effect on Associated Symptoms (Table 7): Group A showed superior relief in nausea (84.31%) and constipation (71.20%). Group B showed superior relief in weakness (69.8%) and vomiting (70.8%). Between-group differences were statistically significant ($P<0.05$) for most parameters.

Effect on Objective Parameters: Hydronephrosis resolution was more pronounced in Group B (26/30 cases, 86.7%) versus Group A (22/28 cases, 78.6%). Group A showed superior reduction in total stone number. Serum calcium showed significant reduction in both groups ($P<0.001$). Urine routine microscopy improved in both groups with reduction in pus cells, RBCs, and crystals.

Safety Assessment: No adverse effects, serious adverse reactions, or treatment-related complications were observed or reported in any participant in either group throughout the 6-month treatment and follow-up period. Both formulations were well-tolerated.

DISCUSSION

Mutrashmarī is a kaphapradhana tridosha disorder in which vitiation of apana vayu plays the principal pathogenic role. The high prevalence among young adult males observed here is consistent with hormonal and occupational factors including vega dharana, a key nidana in Sushruta Samhita [7]. Varunadi kvatha — with principal ingredient varuna (*Crataeva nurvala*) — exerts well-documented antilithogenic and diuretic properties. Lupeol, a bioactive triterpene of Crataeva nurvala, inhibits urinary enzyme activities (N-acetyl-beta-D-glucosaminidase and alkaline phosphatase) implicated in calcium oxalate crystal adherence [17]. Its superior efficacy in reducing constipation and stone number is attributable to bhedana and mutrala properties of its constituents. Prior studies [8,9,21,27] have documented comparable efficacy. Sigrumulatwak kvatha demonstrated superior results in pain relief, dysuria, stone size reduction, and hydronephrosis resolution. The ushna, tikshna, and katu properties of shigru (Moringa oleifera) root bark confer analgesic, anti-inflammatory, and diuretic actions [11,12]. The diuretic effect has been confirmed preclinically [18] and anti-inflammatory effects are mediated via COX-2 and NF-kB inhibition [19]. This study provides the first clinical validation of this formulation in Mutrashmarī. The absence of significant inter-group difference in overall therapeutic outcome validates both formulations as equivalent options, consistent with samya chikitsa in classical Ayurvedic literature. The safety profile — no adverse effects across 200 patients over 6 months — supports their long-term applicability compared to conventional pharmacotherapy [14,20].

Limitations: This study had no placebo control group due to ethical constraints, and its open-label design may introduce performance and detection bias. The single-centre design may limit generalizability. Long-term recurrence data beyond 6 months are unavailable. Stone composition analysis was not performed. A multicentric trial with independent sample size re-estimation is recommended.

CONCLUSION

Both Varunadi kvatha and Sigrumulatwak kvatha demonstrate statistically significant and clinically meaningful efficacy in the management of Mutrashmarī (urolithiasis) with no significant inter-group difference in overall therapeutic outcome. Sigrumulatwak kvatha is hereby clinically validated for the first time, corroborating its classical indication in Ashtanga Hridayam. Both formulations were safe and well-tolerated across 200 patients over 6 months. Larger-scale, placebo-controlled, multicentric randomized trials are recommended to further generalize these findings.

ACKNOWLEDGEMENT

The authors wish to thank the patients who participated in this study and the staff of the OPD of Kayachikitsa and Panchakarma Department for their support. The authors also acknowledge the trial pharmacy for preparation of medicines under expert supervision. This work received no external funding or sponsorship.

DECLARATIONS

Data Availability Statement: The datasets generated and analyzed during the current study are available from the corresponding author on reasonable request. The trial protocol is available through the CTRI registry: CTRI/2024/07/071116 (https://ctri.nic.in).

Declaration of AI in Scientific Writing: The authors confirm that no artificial intelligence (AI) tools were used in the conception, design, data collection, analysis, interpretation, or writing of this manuscript. The manuscript was written entirely by the authors.

Authors' Contribution Statement: Author 1: Conceptualization, study design, patient recruitment, data collection, statistical analysis, and manuscript preparation. Co-Author 2: Supervision, clinical guidance, critical review, intellectual revision, and final approval of the manuscript.

Financial Support and Sponsorship: This study received no financial support or grant from any public, commercial, or not-for-profit organization. The trial medicines were prepared without any commercial or proprietary interest.
Conflicts of Interest: There are no conflicts of interest.

ABSTRACT

Debonding of denture teeth from a heat-cure denture base is a very common problem encountered in the dental operatory. The current study was conducted to do a comparative evaluation of the shear bond strength of cross-linked denture teeth to heat-cure denture base resin with different mechanical modifications of the ridge lap surface. Eighty cross-linked maxillary right central incisors (Premadent brand) of identical mould were chosen for the study. These were stratified into four groups of twenty each. Group I, with no mechanical intervention, served as the control group. Group II, teeth with cingulum-shaped grooves on the ridge lap surface. Group III, teeth with mess-shaped (intersecting) grooves on the ridge lap surface. Group IV, teeth with a combination of both cingulum-shaped and mess-

shaped grooves on the ridge lap surface. All test samples were created using DPI heat-cure denture base resin material. The teeth were positioned at an angle of 130 degrees on the wax models. A continuous shear force was applied to the palatal surface of all eighty specimens using a Universal Testing Machine until debonding of the tooth from the denture base occurred. The comparative analysis of shear bond strength values among different groups prepared with heat-cure denture base resin was found to be statistically significant ($P < 0.05$). Group I showed the lowest mean shear bond strength (449.6 N), followed by Group II (550.5 N) and Group III (612.4 N). Group IV showed the highest mean shear bond strength (660.8 N). Mechanical modifications on the ridge lap surface significantly improve the shear bond strength of cross-linked denture teeth to heat-cure denture base resin. The combination of cingulum-shaped and mess-shaped grooves showed the highest shear bond strength. This suggests that the combined modification on the ridge lap surface may serve as a reliable approach for retention of teeth to the denture base.

Keywords: Shear Bond strength, cingulum-shaped groove, mess-shaped grooves, Denture base Resin, Ridge Lap Surface, and cross-linked denture teeth.

INTRODUCTION

Complete Dentures remain one of the most widely adopted prosthetic solutions prescribed for the rehabilitation of completely edentulous patients. [1] Furthermore, it can restore function, aesthetics, phonetics, and patient confidence in both cost-effective and non-invasive manner, which has maintained their continued relevance even in an era of implant-supported prosthetics. [2,3] However, the durability and reliability of these dentures depend not only on the quality of the impression or occlusion of the teeth or the denture base extension, but also on the integrity of the bond that holds the artificial teeth to the denture base. When this bond between artificial teeth and the denture base fails, it leads to debonding or the detachment of denture teeth from their base. Prior studies have documented this problem, reporting that debonding with no observable defect to the denture teeth or the denture base accounted for nearly one-third of all denture repairs encountered in the dental operatory, making it a recurring clinical challenge. [4,5] The bond established at the ridge lap surface of the denture depends on multiple parameters. This includes both chemical and mechanical alterations for improving the strength of the bonding. Previous studies have tried to improve the strength between the denture teeth and the denture base by making mechanical alterations to the ridge lap surface. A study by Yadav NS et al. concluded that detachment of the tooth from the denture base occurs due to cohesive failure rather than adhesive failure at the ridge lap interface. [6] To mitigate this risk of cohesive failure, Akin HK asserted the necessity of surface treatments. [7] In their 1986 study, Cardash et al. established that there was no statistically significant improvement in retention, regardless of different geometric configurations of the grooves prepared at the ridge lap interface. [8] In contrast to their earlier findings, Cardash et al. demonstrated that preparation of vertical groove configurations across the ridge lap interface resulted in better retention of teeth to the denture base. [9] The prevailing literature presents conflicting and fragmented data. To date, the benefit of mechanical alterations on the ridge lap interface to enhance retention of denture teeth to their denture base remains ambiguous. To address this gap, the present study made an attempt to do a comparative evaluation of the shear bond strength of cross-linked denture teeth to the denture base with various mechanical alterations.

Aims and Objectives

- To determine the baseline shear bond strength of heat-cure denture base resin with denture teeth without any mechanical alterations on the ridge lap surface.
- To determine the shear bond strength of heat-cure denture base resin with denture teeth with cingulum-shaped grooves on the ridge lap surface.

- To determine the shear bond strength of heat-cure denture base resin with denture teeth with mess-shaped (intersecting) grooves on the ridge lap surface.
- To determine the shear bond strength of heat-cure denture base resin with denture teeth with both cingulum-shaped and mess-shaped grooves on the ridge lap surface.
- To comparatively analyse the shear bond strength of heat-cure denture base resin with denture teeth modified with cingulum-shaped grooves, mess-shaped grooves, both cingulum-shaped and mess-shaped grooves and denture teeth with no mechanical alterations on the ridge lap surface.

MATERIALS AND METHODOLOGY

Specimen preparation

Eighty cross-linked acrylic resin maxillary right central incisors (Mould 11) (Premadent) of similar dimensions and morphology were used to ensure uniformity across the study. These specimens were processed with heat-polymerised denture base resin (DPI). The total sample size was stratified into 4 distinct groups (n = 20 per group) based on the mechanical alterations prepared on the ridge lap surface.

Group 1: Denture teeth with no mechanical alterations, as received by the manufacturer, served as the control for the determination of baseline shear bond strength.

Group 2: Denture teeth with cingulum-shaped grooves measuring 2 mm in width and 2 mm in depth prepared on the ridge lap surface using a carbide bur.

Group 3: Denture teeth with mess-shaped (intersecting) grooves measuring 2 mm in width and 2 mm in depth, prepared on the ridge lap surface using a carbide bur.

Group 4: Denture teeth with a combination of both cingulum-shaped grooves measuring 2mm in width and 2mm in depth and mess-shaped (intersecting) grooves measuring 2 mm in width and 2 mm in depth, prepared on the ridge lap surface using a carbide bur.

Wax Model Fabrication

To simulate intraoral conditions, the central incisors were positioned at an angle of 130 degrees on the custom wax model. This mirrors the average functional contact angle between maxillary and mandibular dentition. This orientation is supported by studies of Barpal D et al. [10]. To achieve identical geometric orientation, a wax pattern of dimensions 30 X 8 X 3 mm was fabricated to form a polyvinyl siloxane (PVS) putty matrix. The teeth were repositioned in the putty matrix, and modelling wax was poured to produce eighty identical patterns. The wax configurations were finally flasked and processed using a heat-polymerised denture base resin (DPI). These specimens were evenly distributed into four cohorts of twenty specimens each.

Flask investment and Dewaxing

The completed wax patterns were invested in a two-piece denture flask using Type III dental stone mixed according to the manufacturer's instructions to prevent any discrepancies. After setting for one hour, the flasks were subjected to five minutes of boiling to execute the dewaxing stage. This step facilitated the complete elimination of wax from the mould cavity walls to prevent residual wax contamination.

Polymerisation of specimens

Based on established literature guidelines, the heat-cure acrylic resin was mixed in a proportion of 3:1 polymer to monomer ratio by volume. [11] The mixture was mixed and allowed to progress to a dough stage consistency. Following incremental packing into the mould cavity, the flask was clamped, and a continuous pressure of 20 kN for 30 minutes was applied for definitive adaptation and tooth immobilisation. [12] After one hour of bench equilibrium at room temperature, the flasks were then submerged in boiling water in an acrylizer for polymerization and processed as per the manufacturer's instructions. After polymerisation, gradual bench-cooling was utilised prior to

deflasking to reduce internal thermal stress. Following deflasking, dentures were finished using carbide burs and polished with pumice slurry to eradicate irregularities on the surface. (Figure 1)

Shear Bond strength test

Following finishing and polishing, all eighty specimens underwent shear bond strength under standard laboratory conditions at SGT University, Gurugram, India. Testing was conducted using a computerised universal testing machine (Model EZ20, maximum capacity 20 kN; Hounsfield, Lloyd Instruments, Ametek Technologies, UK) to ensure a precise application of load. Each tooth specimen was secured individually in a custom metallic fixture to prevent any displacement during testing. A shear load was applied on the palatal aspect of each central incisor using a pin of 1 mm diameter made up of stainless steel. [13] The speed of the cross-head was maintained at a constant rate of 5 mm/min until debonding of the tooth occurred. The peak load at which debonding occurred was recorded for each specimen.

Statistical Analysis:

All the data recorded from the shear bond strength testing were statistically analysed using SPSS (Statistical Package for Social Sciences) version 21.0 and Epi-Info version 3.0 software. For comparison of means across multiple groups, a one-way Analysis of Variance (ANOVA) test was applied. Statistical significance level was set at $p < 0.05$. Following the one-way ANOVA test, the Newman-Keuls Range Test was then applied for analysis.

RESULTS

Table I show values recorded across all four groups, and a graphical illustration of these values is presented in Graph 1. The comparative analysis of mean shear bond strength values across all four groups showed statistically significant differences ($p < 0.05$), which confirms that mechanical alterations created on the ridge lap surface influenced the bond strength between the tooth and the denture base. Group I, with no mechanical alterations on the ridge lap surface, served as the control group and recorded the lowest mean shear bond strength across all groups at 449.6 N. This value represents the baseline value, meaning the strength achievable through the bonding of cross-linked denture teeth and the heat-cure denture base resin, without any mechanical alterations on the ridge lap surface. Group II, with a cingulum-shaped groove, measured 2 mm in width and 2 mm in depth on the ridge lap surface, showed a mean shear bond strength of 550.5 N. This value was statistically significantly greater than the control group. This improvement proved that the introduction of a single curved groove configuration at the ridge lap surface can enhance the bonding between the tooth and the denture base Group III, with a mess-shaped (intersecting) groove on the ridge lap surface, recorded a mean shear bond strength of 612.4 N. This value was statistically significantly greater than both the control group and Group II. This suggests that intersecting groove patterns create a wider and more complex network of bonding between teeth and the denture base. Thereby increasing mechanical resistance to shear displacement. Group IV, with a combination of both cingulum-shaped and mess-shaped grooves on the ridge lap surface, showed the highest mean shear bond strength across all four groups at 660.8 N. This value was statistically significantly greater than all three groups, which suggests that a combination of these mechanical alterations on the ridge lap surface could significantly enhance bonding strength between denture teeth and the denture base. These results demonstrated a progressive hierarchy of shear bond strength values corresponding to increasing complexities of the ridge lap surface alterations, from the group with no mechanical alterations through to the group with combined groove alterations on the ridge lap surface.

DISCUSSION

Debonding of denture teeth from their denture base remains one of the most frequently encountered complications encountered in the dental operatory. The integrity of the tooth-denture base bonding is a fundamental factor that determines the retention of the tooth to the denture base. When there is adequate bonding between the tooth and the

denture base, the teeth function as an integral component of the prosthesis, thereby contributing to its stiffness, distribution of load, and strength. [14] Studies exist that have quantified the scale of the problem and reported that debonding accounts for one-third of all the denture repairs encountered in the dental operatory. Among the types of artificial teeth available in the market for denture construction, acrylic teeth remain the gold standard due to their inherent property of bonding to denture base resin during polymerisation. [15] Unlike porcelain teeth, acrylic teeth better bond with the denture base resin. G Jain et al., in their 2024 study, chemically approached this complication by application of dichloromethane to the ridge lap surface before the dough stage packing, which significantly enhanced the bond strength between denture teeth and denture base resin. [16] The bond strength increased significantly due to the partial dissolution of the cross-linked surface layer. Due to the limitations associated with solvent-based treatments, including occupational health hazards, mechanical alterations are simpler and safer in the dental operatory.

The mechanical alterations on the ridge lap surface through the preparation of grooves on the ridge lap surface have been one of the most extensive study areas, yet the published evidence is limited and fragmented. Studies exist that have demonstrated the preparation of vertical grooves on the ridge lap surface produced statistically significant improvement in tooth retention to the heat-cure denture base resins. A study of Civjan et al. further supported this approach by suggesting that systematic grinding of the ridge lap surface was sufficient to achieve increased retention of teeth to the denture base resin. [17] Due to limited and fragmented data, the current study was done to compare the shear bond strength achieved by three distinct mechanical alterations: cingulum-shaped grooves, mess-shaped (intersecting) grooves, and a combination of both cingulum-shaped and mess-shaped grooves, against a control with no mechanical alterations on the ridge lap surface. The findings of this study showed a progressive hierarchy of statistically significant improvement in the shear bond strength with increasing complexity on the ridge lap surface.
The control group with no mechanical alterations on the ridge lap surface showed the lowest mean shear bond strength across all four groups at 449.6 N. Reflecting the baseline value, meaning the strength achievable through the bonding of cross-linked denture teeth and the heat-cure denture base resin without any mechanical alterations on the ridge lap surface.

Group II, with a cingulum-shaped groove on the ridge lap surface, showed a mean shear bond strength of 550.5 N. This value was statistically significantly greater than the control group and is consistent with those reported by Zuckerman. [18] This improvement suggests that the introduction of a single curved groove geometry at the ridge lap surface can enhance the bonding between the tooth and the denture base. This geometry produces a more reliable and consistent bond between the tooth and the denture base. Group III, with a mess-shaped (intersecting) groove on the ridge lap surface, recorded a higher mean shear bond strength of 612.4 N, statistically significantly greater than both the control group and Group II. This suggests that intersecting groove patterns create a wider and more complex network of bonding between teeth and the denture base. Thereby increasing mechanical resistance to shear displacement. Group IV, with a combination of both cingulum-shaped and mess-shaped grooves on the ridge lap surface, showed the highest mean shear bond strength across all four groups at 660.8 N. This value was statistically significantly greater than all three groups, which suggests that a combination of these mechanical alterations on the ridge lap surface could significantly enhance bonding strength between denture teeth and the denture base. This combined groove can accommodate a significant volume of interlocking resin, and the complexity of the geometry produced a bond that qualitatively differs in its resistance to masticatory and occlusal forces.

The findings of this study align with the broader body of the literature supporting the efficacy of the preparation of the groove on the ridge lap surface, which enhances the bond between the tooth and the denture base. Moreover, the current study extends the existing evidence base by demonstrating that the creation of grooves on the ridge lap surface produces a statistically significant impact on the bond strength between teeth and the denture base. The progressive hierarchy of shear bond strength across multiple groups yields a clinically actionable conclusion that the preparation of the groove on the ridge lap surface is essential when processing highly cross-linked artificial teeth with heat-cure denture base resin, and the simultaneous preparation of both cingulum-shaped and mess-shaped grooves represents the most effective strategy for mechanical modification.

CONCLUSION

Mechanical alterations, such as preparation of the groove on the ridge lap surface, significantly enhance the strength of the bond between artificial teeth and heat-polymerised denture base resin. The specimen group with both the combinations of cingulum-shaped and mess-shaped (intersecting) grooves yields the highest shear bond strength in comparison to the specimen group with no mechanical alterations. Moreover, this combined configuration represents an effective strategy to optimise the retention of artificial teeth with the denture base.

ABSTRACT

In India, intimate partner violence remains widespread issue, and national estimates from the National Family Health Survey (NFHS-5, 2019-21) and related analyses show persistent prevalence and sharp regional disparities. The study examines how prevailing biomedical approaches to trauma obscure the social sources of suffering among survivors of intimate partner violence and proposes an integrated care framework that centers structural determinants. Adopted a qualitative analytical design based on secondary data, national survey evidence, research papers, and policy documents. Drawing on national prevalence data, qualitative studies of disclosure and medico-legal practice and evaluations of state responses such as the One Stop Centre model, the analysis identifies three core problems: clinical reductionism that locates trauma within individual bodies and symptoms; institutional barriers, including medico-legal bottlenecks and low provider competency that limit help-seeking and continuity of care; and intersectional vulnerabilities shaped by caste, religion, indigeneity and poverty. The study documents how the COVID-19 shadow pandemic amplified these dynamics and reports gaps in One Stop Centre implementation and funding. In response, it specifies a three pillar Integrated Care Model that is structural competency and trauma informed practice, economic empowerment and social safety nets, and community engagement with task shifting as a pragmatic policy and clinical pathway. The conclusion argues that addressing intimate partner violence effectively requires shifting attention from diagnosis alone to the social arrangements that produce and sustain violence

Keywords: Intimate Partner Violence; Structural Violence; Biomedical Model; Trauma-Informed Care; Intersectionality

INTRODUCTION

In India intimate partner violence remains widespread; national estimates from the National Family Health Survey (NFHS-5) (2019–21) and recent analyses show persistent prevalence and sharp regional disparities. These epidemiological patterns associated with evidence of disclosure barriers and limits of facility-level responses, the study's aim to relocate trauma from individual diagnosis toward the social arrangements that produce violence. The clinical landscape of trauma in contemporary India is increasingly defined by a tension between the expansive, systemic reality of intimate partner violence (IPV) and the reductive, diagnostic focus of the biomedical model. While the National Family Health Survey (NFHS-5, 2019–2021) provides a statistical architecture for understanding the scale of violence with 29.3% of women aged 18–49 reporting physical violence since the age of 15 (Manna et al., 2024).This quantitative frame coexists with analyses that draw on national samples to identify predictors and regional disparities (Mishra et al., 2024; Dalal et al., 2025). Yet the qualitative experience of survivors remains largely obscured by institutional frameworks that prioritize medicalization over structural transformation a dynamic vividly documented in studies of barriers to disclosure within tertiary psychiatric settings (Vranda et al., 2018). This study contends that prevailing trauma-care models which emphasize individual diagnosis and clinical symptom reduction which fundamentally misrecognize the nature of social suffering experienced by IPV survivors. By adopting on the theoretical model of structural violence and critical medical anthropology the present study's analysis seeks to relocate the problem of trauma from the interiority of the survivor's psyche to the social arrangements that produce and sustain violence. The ensuing discussion articulates the necessity of a paradigm shift toward an integrated care model that addresses social determinants of health and dismantles the institutional barriers that currently impede recovery for the most marginalized women in India.

METHODS AND STUDY MATERIAL

The study adopts a qualitative analytical research design that integrates secondary quantitative evidence with thematic synthesis of existing scholarly and policy literature. The purpose of the study is to examine how biomedical approaches to trauma in cases of intimate partner violence (IPV) in India often overlook structural and social determinants of violence. By illustration on national epidemiological data and critical theoretical perspectives from medical anthropology the present study evaluates the limitations of clinical responses and explores alternative integrated models of care. The research follows an interpretive sociological approach combining descriptive analysis of national prevalence data with conceptual analysis of healthcare responses to IPV. The framework of structural violence and critical medical anthropology guides the interpretation of findings.

The study relies primarily on secondary data drawn from three categories of sources. First, nationally representative datasets were used to understand the prevalence and patterns of intimate partner violence in India. Data from the National Family Health Survey rounds (NFHS-3, NFHS-4 and NFHS-5) were consulted to identify trends in domestic violence across time and regions. Second, peer-reviewed academic literature on domestic violence, trauma and healthcare responses was examined. These sources include studies published in journals related to public health, sociology, medical ethics and gender studies. The literature provides insights into barriers to disclosure, provider attitudes and institutional responses to IPV in healthcare settings. Third, policy documents, government reports and program evaluations were reviewed to understand institutional interventions addressing gender-based violence. These include reports on the One Stop Centre scheme, healthcare response frameworks and community-based interventions implemented by governmental and non-governmental organizations.

Relevant literature was identified through structured searches in academic databases such as Google Scholar, Pub Med and Scopus using keywords including "intimate partner violence," "domestic violence in India," "trauma-informed care," "healthcare response to IPV," and "structural violence." Additional sources were obtained from institutional websites and policy reports related to gender-based violence interventions in India. Studies were

selected based on their relevance to three key themes: prevalence and epidemiology of IPV in India, healthcare system responses to domestic violence and socio cultural factors influencing disclosure and help-seeking behavior. Both empirical research studies and systematic reviews were included in order to capture a comprehensive understanding of the issue. The collected literature and data were analyzed using thematic analysis. Following the analytical framework proposed by Braun and Clarke (2006), the study identified recurring themes related to the medicalization of trauma, institutional barriers within healthcare systems and socio cultural factors shaping survivor's help-seeking behaviors. The thematic analysis involved several stages. First, relevant texts were read repeatedly to identify key concepts and patterns. Second, codes were generated to categorize recurring issues such as biomedical reductionism, provider competency gaps, medico-legal challenges and structural barriers to care. Third, these codes were grouped into broader themes that explain how healthcare systems respond to domestic violence and why existing biomedical models remain insufficient. The interpretation of these themes was guided by the theoretical perspectives of critical medical anthropology and structural violence which emphasize how social inequalities, gender norms and institutional power structures shape health outcomes and access to care.

The Epidemiological Landscape: NFHS-5 and the Persistence of Spousal Violence

The statistical profile of IPV in India is a critical starting point for any structural analysis (Mishra et al., 2024; Manna et al., 2024). The transition from NFHS-4 (2015–16) to NFHS-5 (2019–21) offers a longitudinal view of the domestic environment by revealing that despite minor fluctuations spousal violence remains an endemic feature of the Indian family structure (NFHS-5, 2019–21; Dalal et al., 2025). The national weighted prevalence of domestic violence against women was recorded at 31.2% in NFHS-5 a slight decrease from the ~33% reported in NFHS-4, yet the absolute volume of women affected continues to represent a public-health crisis of monumental proportions (NFHS-5, 2019–21; Mishra et al., 2024). The distribution of this violence is characterized by profound regional variations, suggesting that state-level policy, local cultural norms and socioeconomic development play decisive roles in shaping the safety of the domestic sphere (Manna et al., 2024; Dalal et al., 2025). A granular examination of the data reveals that states like Karnataka (44.4%), Bihar (40.0%), Manipur (39.6%) and Telangana (36.9%) exhibit prevalence rates that significantly exceed the national average. In Karnataka, the proportion of married women who have ever faced spousal violence doubled between survey rounds that rising from 21% to 44%, a trend that demands a critical inquiry into the local drivers of domestic aggression. Conversely, Tripura witnessed a consistently decreasing rate across all three forms of violence indicating that progress is possible when specific socio-economic factors and interventions are aligned (Bhatia, 2023).

The impact of the COVID-19 pandemic introduced a "shadow pandemic" that complicated the trajectory of these statistics. Mandatory social isolation and lockdowns increased the exposure of women to their abusers while simultaneously dismantling their access to external support mechanisms (Tmava & Burstein, 2025). In urban areas, domestic violence complaints reportedly doubled following the imposition of nationwide restrictions with the Tamil Nadu Police registering at least 40 cases per day during the height of the lockdown (Bhatia, 2023; Tmava& Burstein, 2025). This period highlighted the fragility of the Indian healthcare and legal response system which in its urgency to address the biomedical threat of the virus further marginalized the needs of IPV survivors leading to a "narrative compression" that silenced their ongoing suffering (Tmava & Burstein, 2025).

Intersectional Vulnerability: Caste, Religion and the Political Economy of Violence

A robust analysis of IPV in India must move beyond the Universalist category of "woman" to engage with the intricate interactions of caste, religion, class and geographic location. In the Indian context, intersectionality is not merely an academic concept but a lived reality that defines who is vulnerable to violence and who has the resources to escape it. The interaction of gender with the caste hierarchy is particularly significant as Dalit and Adivasi women occupy a social position characterized by "intersectional violence" where oppression is layered due to their specific marginalized identity (Khalid & Bouakaz, 2025).

The Caste-Patriarchy Nexus and the IPV Gap

The prevalence of IPV among Scheduled Caste (SC) women stands at 37.3% compared to 24.4% among women in the "General" category. This gap of 12.9 percentage points is not a result of individual pathology but is driven by systematic disparities across nearly all social determinants of health. Using Fairlie decomposition analysis, researchers have identified that approximately 84% of this gap can be attributed to specific socio-economic and behavioral predictors with the remainder likely tied to unmeasured factors such as the psychological stress of systemic casteism (Chowdhury et al., 2022). The data suggests that for SC women, violence is frequently mediated by the structural violence of economic precarity. Wealth status alone explains nearly a quarter of the disparity, illustrating how poverty functions as an enabling condition for domestic abuse. Furthermore, the prevalence of controlling behaviour such as restricting contact with family, monitoring movements and financial distrust is significantly higher among husbands in SC households, often associated with a four-fold increase in the likelihood of physical violence. This proposes that IPV is used as a mechanism to assert power within a domestic sphere when external social structures systematically disempower the male head of the household (Chowdhury et al., 2022).

Tribal Vulnerabilities and Indigenous Idioms of Distress

For Adivasi (Scheduled Tribe) women, the experience of violence is often compounded by geographic isolation and the transformation of traditional social structures (Bhasin, 2007). In communities like the Gaddi tribal community of Himachal Pradesh, women express their distress through the polysemic term "tension," which serves as an idiom for the embodied strains of politico-economic and social transformation. This "tension" is not merely a psychiatric symptom but a social critique of the patriarchal norms and oppressive standards that frustrate women's agency (Lester, 2013). In some tribal contexts, this distress may manifest as "spirit possession," which local communities interpret either through exorcism or the domestication of the spirit, allowing the woman to gain a degree of social status and attention that the formal healthcare system denies her (Lester, 2013; Bhasin, 2007). The structural violence faced by tribal women also includes the risk of being targeted through witchcraft accusations. Scholars identify witchcraft practices as the outcome of complex intersectional power structures involving gender, caste and land rights. Such accusations often serve as a social mechanism to displace women from ancestral lands or to punish those who challenge traditional hierarchies, further illustrating that the "trauma" of Adivasi women is deeply rooted in the struggle for survival and sovereignty (Khalid & Bouakaz, 2025).

Intersectional Vulnerability: Caste, Religion, and the Political Economy of Violence

Muslim women in India navigate a specific intersection of gender-based oppression and religious discrimination, often finding themselves "multiply marginalized" within the broader socio-political climate (Khalid, S. & Bouakaz, 2025). Research based on National Family Health Survey (NFHS-5) data indicates that religious minority women are significantly more likely to experience physical violence during pregnancy compared to those in the majority religion (Kalra et al., 2025). The vulnerability of South Asian women including those of Muslim faith is often exacerbated by a lack of trust in healthcare systems where they anticipate judgmental attitudes, a lack of privacy or a failure by providers to understand their specific cultural and religious contexts (Baloch et al.,2025). This leads to a situation where the fear of institutional discrimination acts as a barrier to help-seeking trapping survivors between a violent domestic environment and a hostile public sphere (Khalid & Bouakaz, 2025). The dominance of the biomedical model in trauma care has led to what Arthur Kleinman and his colleagues terms the "medicalization of social suffering," a process that transforms the effects of structural violence into individual clinical pathologies (Kleinman et al., 1997). By framing IPV-related distress primarily as post-traumatic stress disorder (PTSD) or depression, the biomedical model performs a "double erasure": it obscures the social origins of the suffering and depoliticizes the violence against women (Tmava& Burstein, 2025). Recent critiques of biomedical reductionism in chronic health conditions further support the need for integrated functional models that explicitly incorporate social determinants of health (Pianese& Bordoni, 2025).

The Critique of Biomedical Reductionism

Critical Medical Anthropology (CMA) provides a necessary corrective to this reductionism by analyzing the clinic as a site of power where knowledge about health and vulnerability is governed. As Arthur Kleinman argues the PTSD framework as formalized in the Diagnostic and Statistical Manual of Mental Disorders, Third Edition (DSM-III), established a diagnostic category that individualizes social problems locating the pathology within the survivor rather than in the social conditions that produce violence (Kleinman, 1997; American Psychiatric Association, 1980). In the India context, this model often fails to account for social determinants, embodied idioms of distress and culturally specific help-seeking patterns, a limitation underscored by recent critiques calling for integrated functional approaches that incorporate social and structural factors (Pianese & Bordoni, 2025).

- **Somatic Expressions of Trauma:** Many Indian survivors present with somatic complaints such as chronic pain, headaches or gastrointestinal disturbances (Barakati et al., 2026)that do not map neatly onto Western psychiatric categories.
- **Existential and Spiritual Distress:** Concepts of healing in India are often embedded in religious or community-based frameworks that emphasize social harmony and spiritual balance over individual symptom reduction (Bhasin, 2007).
- **Ongoing Structural Harm:** Clinical interventions that focus on "recovery" from a past event are inadequate for survivors living in conditions of continuous structural violence such as chronic poverty or caste-based exclusion (Tmava & Burstein, 2025).

Paul Farmer's concept of structural violence is pivotal for understanding how social arrangements such as gender wage gaps, patriarchal family structures and regional disparities in infrastructure of harm survivors (Farmer, 2004). These structures are not incidental to IPV but are constitutive of it. For instance the gender wage gap and the restriction of women to informal and insecure labor markets ensure economic dependency on abusive partners. Similarly the geographic mal distribution of healthcare facilities means that rural women must travel long distances to access care facing transportation costs and safety concerns that make "seeking help" a structurally impossible task for many (Khalid & Bouakaz, 2025).

The Medico-legal Bottleneck

One of the primary structural barriers is the "medico-legal" nature of domestic violence cases. In many Indian tertiary hospitals providers share an apprehension about dealing with the criminal justice system. Police involvement is a primary deterrent for both physicians and patients. For the physician it marks the beginning of a complex legal process that they feel unprepared to handle and for the patient it invokes fear and social stigma. A review of Standard Operating Procedures (SOPs) at six major hospitals in West Delhi revealed that most failed to recognize the medico-legal significance of IPV, often classifying these cases as general "alleged physical assault" rather than specifically as domestic violence (Sehra, 2025). The qualitative insights from the West Delhi study underscore how "poor documentation practices" in medical records compromise the reliability of evidence, hinder the assessment of patterns and obstruct effective intervention. When a survivor presents with "multiple injuries," "delayed presentation," or "history of loss of consciousness," these are clinical red flags for IPV; however, without a standardized protocol that demands the recording of the perpetrator's identity and the context of the abuse. These findings are treated as isolated physical symptoms rather than evidence of systematic harm (Sehra, 2025).

Provider Attitudes and the Mastery of IPV Competencies

The effectiveness of the healthcare response is further limited by a "mastery gap" among medical professionals. A survey of medical students in comparable Global South contexts revealed critically low levels of knowledge and skills regarding IPV, with mastery levels consistently falling below 80% (Manuel, B. et al., 2019). In India, providers often report feeling "uncomfortable" or "not confident" in inquiring about domestic violence, citing a fear of offending the patient or an ignorance about how to ask (Barakati, T. et al., 2026; Sehra, L., 2025). This discomfort is often rooted in the internalization of patriarchal norms where marital violence is seen as a "private issue" or something to be "socially tolerated" for the sake of family honor (Barakati, T. et al., 2026).

Evaluating State Interventions: The 'Sakhi' One Stop Centre (OSC) Model

In response to these systemic failures, the Government of India launched the One Stop Centre (OSC) scheme, also known as Sakhi Centres, in 2015 (Rajan, 2025; Ministry of Women and Child Development, 2025). Funded through the Nirbhaya Fund, the OSC model aims to provide an integrated support system including medical assistance, legal aid, police facilitation, psychosocial counselling and temporary shelter under one roof (Ministry of Women and Child Development, 2025; Rajan, 2025).

One Stop Centre Scheme (Operational Strengths and the 2025 Status)

As of late 2025, over 12.67 lakh women have been assisted by OSCs across India and the scheme has expanded significantly with 865 operational centers nationwide and the integration of the Women Helpline (181) with the Emergency Response Support System (112) in several states/UTs (Press Information Bureau, 2026; Ministry of Women and Child Development, 2025). The recent introduction of the "Mission Shakti Dashboard" and a comprehensive Standard Operating Procedure (SOP) in 2025 represents a critical step toward standardizing service delivery and ensuring transparency in fund utilization (Ministry of Women and Child Development, 2025; Engender Health, 2025).

Systemic Challenges and Implementation Gaps

Despite its ambitious design, the OSC model faces persistent challenges that impede its full potential. The most glaring issue is the underutilization of funds; for instance, only ₹328 crore out of an allocated ₹735 crore were utilized in certain periods with states like Bihar and Karnataka using the least amount despite their high IPV prevalence (Engender Health, 2025; Rajan, 2025). Additionally, high attrition rates among staff driven by low salaries and a lack of annual increments adversely impact continuity of care (Rajan, 2025). In rural areas the lack of visibility remains a major barrier as many women are unaware of OSC services and many centers lack essential amenities such as accessible toilets or reliable power (Engender Health, 2025).

The Proposed Integrated Care Model: A Multi-Sectoral Blueprint

Moving beyond the clinic requires a conceptual shift toward an "Integrated Care Model" that addresses both the immediate symptoms of trauma and the structural conditions that perpetuate violence. This model informed by recent programmatic successes (Engender Health, 2025) which emphasizes three core pillars: structural competency, economic empowerment and community-based advocacy.

Pillar 1: Structural Competency and Trauma-Informed Care (TIC)

Healthcare systems must move from cultural competency to structural competency the capacity to recognize and respond to the social and political forces that shape health (Scott et al., 2025). This involves:

- Standardized IPV screening: Implement routine, trauma-informed screening across departments, particularly antenatal and psychiatric clinics where disclosure is most likely to occur (Sabri et al., 2024).
- Refining documentation: Develop electronic health records that allow for joint patient files shared between medical and legal teams ensuring that patterns of abuse are visible to all stakeholders (Ministry of Women and Child Development, 2025).
- Structural differential: Train physicians to construct a "structural differential" by identifying how factors like lack of housing or economic abuse contribute to presenting symptoms (Scott et al., 2025; Sawah et al., 2025).

Pillar 2: Economic Empowerment and Social Safety Nets

The IPV gap between poor and non-poor women underscores the role of economic independence in survivor safety (Sen et al., 2026). An integrated model must incorporate:

- Livelihood integration: Link healthcare facilities and OSCs to vocational training and microfinance programs to address the financial constraints that prevent women from leaving violent homes (Vimala, 2025; Daruwalla et al., 2024).

- Direct cash transfers: Use flexi-funds within the Mission Shakti vertical to provide immediate financial relief for survivors seeking to escape unsafe environments (Ministry of Women and Child Development, 2025.

Pillar 3: Community Engagement and "Task-Shifting"

Given the geographic disparities in healthcare in India the model must rely on cascade training for community health workers (ASHAs and Anganwadi workers) (Engender Health, 2025).

- **Bystander Mobilization:** Training youth and males as "GBV prevention champions" to shift the gender norms that currently justify wife-beating in 35% of households (Engender Health, 2025).
- **Peer Facilitators:** Sources from community and slum settings further supports locally tailored, community-driven approaches to address IPV during and after pregnancy (Das et al., 2013). Finally, using trained lay peer facilitators to provide first-line psychological support and to help survivors navigate referral pathways has shown promise in integrated domestic-violence and reproductive-health interventions (Sabri et al., 2024).

Policy Recommendations: Strengthening the National Response

To fully realize the potential of the integrated care model below are the specific policy recommendations are proposed:

- **Standardize Medico-legal Protocols:** The Ministry of Health and Family Welfare (MoHFW) must mandate the categorization of all domestic violence cases as Medico-legal Cases (MLCs) with specific SOPs for documentation regardless of whether the patient chooses to pursue a police complaint immediately.
- **Institutionalize Structural Competency Training:** Incorporate structural competency and trauma theory-based training into the undergraduate medical curriculum (MBBS) and nursing education moving beyond technical identification to foster critical reflections on gender and power.
- **Enhance Human Resource Retention:** Address the high attrition rates in OSCs by implementing a standardized salary structure with a 3% annual increment, equivalent to provisions in other national welfare schemes like Mission Vatsalya.
- **Co-location and Digital Integration:** Scale up the model of co-locating Anganwadi centers and OSCs within school or hospital premises to increase visibility and ease of access for women in rural districts.
- **Strengthen Accountability through Data:** Expand the use of the Mission Shakti Dashboard to include qualitative metrics of survivor satisfaction and successful "recovery outcomes" (e.g., attainment of housing or employment), moving beyond simple counts of women assisted.

CONCLUSION

Toward a Paradigm of Social Healing

The trauma of intimate partner violence in India is a phenomenon that transcends the boundaries of clinical diagnosis. While the biomedical model provides essential tools for physical recovery and symptom management it remains insufficient as a stand-alone response to a crisis rooted in structural violence. The persistence of IPV particularly among Dalit, Adivasi and religious minority women underlines the reality that "recovery" is a socio-political project as much as a medical one. The findings of this report suggest that the path toward genuine healing for survivors requires a fundamental reorganization of the healthcare encounter. By integrating social determinants of health, refining the medico-legal response and empowering community-based support networks, India can move from a paradigm of "treatment" to one of "transformation". The success of the Sakhi One Stop Centre model while currently hampered by operational hurdles offers a blueprint for a multi-sectoral approach that recognizes the interconnectedness of medical, legal and economic needs. Only by addressing the structural roots of violence and dismantling the institutional barriers to care can we support a future where the trauma of India's women is recognized, documented and finally overcome.

Table 1: The Epidemiological Landscape: NFHS-5 and the Persistence of Spousal Violence

Indicator for Women (15-49 Years)	NFHS-3 (2005-06) (%)	NFHS-4 (2015-16) (%)	NFHS-5 (2019-21) (%)
Emotional Violence	14.0	14.0	13.1
Physical Violence	31.0	30.0	28.5
Sexual Violence	8.0	7.0	5.7
Physical Violence during Pregnancy	3.7	3.9	2.4
Total Spousal Violence (any form)	37.2	33.3	31.2

Table 2: The Caste-Patriarchy Nexus and the IPV Gap

Contributing Factor to the SC-General IPV Gap	Contribution to the Disparity (%)
Husband's Alcohol Consumption	26.33
Household Wealth Index	24.48
Husband's Controlling Behavior	24.00
Intergenerational Exposure (Parental IPV)	15.87
Number of Living Children (Son Preference)	4.26
Women's Acceptance of Violence Norms	3.86
Working Status of Women	2.87

Table 3: The Medico-legal Bottleneck

Institutional and Systemic Barrier	Impact on Survivor Care and Safety
High Patient Volume/Load	Prevents physicians from dedicating time for trust-building and disclosure.
Lack of Private Space in OPD	Makes confidential conversations about abuse nearly impossible in government facilities.
Focus on Physical Trauma Only	Overlooks chronic mental health needs and somatic indicators of prolonged abuse.
Fear of "Legal Entanglements"	Encourages providers to avoid documenting the domestic nature of the violence.
Inadequate Documentation	Compromises the reliability of evidence for future legal and protection efforts.

Table 4: One Stop Centre Scheme (Operational Strengths and the 2025 Status)

OSC/Sakhi Service Component	Functional Role in Survivor Recovery
Emergency Rescue	Immediate extraction from violent domestic or public spaces.
Medical Assistance	Linking survivors to hospitals for treatment and forensic examination.
Psychosocial Counselling	Addressing anxiety, trauma and emotional stability through multidisciplinary teams.
Legal Aid & Advice	Facilitating the filing of complaints and navigating the court system.
Temporary Shelter	Providing safe housing for women and their children for up to five days.

ABSTRACT

The objective of the present investigation was to formulate and assess a pH-responsive in-situ hydrogel containing Bromfenac Sodium for prolonged ocular drug delivery. Traditional ophthalmic dosage forms are often associated with rapid precorneal drainage and limited ocular bioavailability, creating a need for improved delivery platforms. In this study, pH-sensitive in-situ hydrogels were developed using Carbopol 940P as the gelling polymer, Hydroxypropyl Methylcellulose (HPMC K4M) as a viscosity-modifying polymer, and β-cyclodextrin as a solubility-enhancing excipient. Thirteen formulations (F1–F13) were prepared and characterized for relevant physicochemical and pharmaceutical attributes. Preformulation investigations, including organoleptic evaluation, melting point analysis, UV spectrophotometry, FTIR, and DSC studies, verified the identity, purity, and compatibility of Bromfenac Sodium with the selected excipients. Post-formulation assessment revealed acceptable pH values (6.9–7.2), rapid gelation (22–30 s), appropriate viscosity, satisfactory spreadability, isotonic behavior, and uniform drug content (90.2–99.5%). HET-CAM evaluation confirmed ocular safety and absence of irritation. In vitro release studies demonstrated sustained drug release for up to 8 h, with formulation F3 showing the highest cumulative release. DOE analysis established that Carbopol concentration exerted a significant effect on viscosity and release performance. The developed pH-sensitive in-situ hydrogel system therefore represents a promising strategy for , providing prolonged drug release, and increasing patient compliance.

Keywords: Bromfenac Sodium, pH-Sensitive In-Situ Hydrogel,Ocular Drug Delivery, Sustained Drug Release, Ophthalmic Formulation

INTRODUCTION

The eye is among the most intricate and delicate organs of the human body, playing a vital role in vision and enabling individuals to perceive and interact with their surroundings. It comprises a highly organized network of anatomical components that function collectively to transform incoming light into neural impulses, which are subsequently processed and interpreted by the brain. [1] Owing to the complexity of ocular anatomy and physiology, there is a continuous need for efficient and reliable ocular drug delivery systems. Over the past few years, considerable efforts have been directed toward the development of advanced drug delivery approaches aimed at overcoming the shortcomings associated with conventional ophthalmic formulations. Among these emerging technologies, in situ gelling systems have attracted substantial attention due to their ability to undergo a sol-to-gel transition following administration**.** In situ hydrogels are polymer-based formulations that remain in a low-viscosity liquid state before instillation and subsequently convert into a gel upon exposure to the physiological environment of the eye.[2] The transformation from sol to gel can be triggered by various environmental stimuli, including alterations in pH, temperature fluctuations, and ionic interactions. Among the different in-situ gelling strategies, pH-responsive hydrogels have emerged as highly effective platforms for ocular drug delivery.[3] These systems possess a transparent and soft consistency, enhancing patient comfort and minimizing ocular irritation during administration. Incorporation of viscosity-enhancing polymers such as Hydroxypropyl Methylcellulose (HPMC) further improves gel strength, rheological properties, and overall formulation stability. In addition, these polymers increase the residence time of the formulation on the ocular surface, thereby facilitating sustained and controlled drug release. Such characteristics are particularly advantageous for therapeutic agents that require prolonged ocular retention and continuous pharmacological action, including anti-inflammatory, anti-glaucoma, antimicrobial, and anti-allergic drugs.[4] Owing to their ability to improve drug retention, enhance bioavailability, and prolong therapeutic efficacy, pH-sensitive in-situ hydrogel systems have attracted considerable interest in pharmaceutical research as advanced ocular drug delivery carriers. Consequently, extensive efforts have been directed toward the formulation and evaluation of these systems for the effective treatment of ocular disorders and postoperative inflammatory conditions. [5]

MATERIAL AND METHOD

Material: Bromfenac sodium was obtained from Indoco Remedies Limeted, Kilolab Navi Mumbai India as a gift sample. Carbopol 934, B-Cyclodextrin and HPMC K4m were purchased from Research-Lab Fine Chem. Industry – Mumbai. All other chemical and solvent were of Pharmaceutical Grade.

Method:

Formulation of ph sensitive in-situ gel:

RESULT AND DISCUSSION

Preformulation study

Organoleptic properties: The organoleptic evaluation of bromfenac sodium showed that it was a yellow, odorless crystalline powder, indicating its pure and well-defined nature.

Melting Point: The observed melting point of bromfenac sodium was 285°C, which was found to be within the reported range of 284–286°C, indicating the purity and identity of the drug substance.

UV Spectrophotometric Analysis

Determinationof(λmax)AndStandard calibration curve in of Bromfenac Sodium in Methanol

Using UV spectroscopy, Bromfenac Sodium s maximum absorption wavelength (λmax) was determined to be 268 nm, as shown in Fig. 2AndA good linear relationship between concentration and absorbance is demonstrated by the

standard calibration curve for Artemether, Its slope is y = 0.0188 x 0.0484 , and its coefficient of regression value is R2 = 0.9965 As shown in Fig 3.

Post Formulation Study

Below is Table 3, which shows the physical parameters of the Ph sensitive In-gels that were created, comprising color, homogeneity, pH, Gelation Time, Drug Content and viscosity.

Spreadability

The spreadability values ranged from 4.90 ± 0.24 to 9.52 ± 0.23 g·cm/sec, indicating differences in consistency and flow characteristics among the prepared formulations. The optimized formulation (F3) exhibited a spreadability value of 7.27 ± 0.22 g·cm/sec with a spreading time of 55.0 ± 1.3 sec. This formulation was considered to provide the best balance between ease of spreading and adequate viscosity.

Isotonicity

The tonicity of formulations F1–F13 was evaluated using red blood cell (RBC) morphology studies to assess their compatibility with physiological fluids. Formulations F2, F3, F5, F7, F9, F11, and F13 maintained the normal biconcave morphology of RBCs, indicating isotonic behavior and excellent compatibility with physiological conditions. In contrast, F1 showed slight cell swelling, indicating a mild hypotonic tendency, while F4, F6, andF10 exhibited slight crenation or mild cell shrinkage, suggesting a slight hypertonic effect. Although these formulations remained compatible and acceptable, minor osmotic stress on RBCs was observed. Furthermore**,** F8 and F12 displayed noticeable cell shrinkage with a hypertonic tendency, resulting in borderline compatibility. The optimized formulation F3 showed the most favorable results, maintaining normal RBC morphology and exhibiting excellent physiological compatibility. These findings confirm that F3 possesses suitable tonicity characteristics for ophthalmic application and is expected to provide enhanced patient comfort and safety during ocular drug delivery. The RBC morphology observed in the images confirms that the tested formulation of the optimized batch F3, is isotonic and physiologically compatible, making it suitable for ophthalmic application.

Analysis of Data

The Design of Experiments (DOE) approach was used to optimize Bromfenac sodium hydrogel formulations by studying the effect of Carbopol, HPMC K4M, and Cyclodextrin on important formulation responses such as solution viscosity (R1), gel viscosity (R2), and drug content (R3). A total of nine formulations were prepared with different concentrations of polymers and excipients to understand their individual and combined influence on the hydrogel characteristics.

Discussion: Viscosity solution (cps) – Counter Plot

The counter plot for viscosity (sol) indicates that the viscosity of the Bromfenac Sodium pH-sensitive in situ hydrogel is predominantly influenced by Carbopol concentration (Factor A), as viscosity increases progressively from approximately 410 to 1260 cps with increasing Carbopol levels. The nearly vertical contour lines suggest that HPMC K15M concentration (Factor B) has minimal influence on viscosity within the studied range, while Carbopol acts as the major determinant of the rheological behavior of the formulation. This increase in viscosity may contribute to enhanced ocular residence time and improved drug retention.

Discussion: Viscosity solution (Cps) – 3D Surface Plot

The 3D surface plot illustrates the combined effect of Carbopol concentration (A)and HPMC K15M concentration (B)on the solution viscosity (R1) of the Bromfenac Sodium hydrogel formulation while keeping Cyclodextrin concentration constant at 15 mg. The graph demonstrated that the viscosity of the hydrogel increased progressively with an increase in Carbopol concentration.

Discussion: ViscosityGel (cps) – Counter Plot

The contour plot for gel viscosity demonstrates that both Carbopol (Factor A) and HPMC K15M (Factor B) influence the viscosity of the formed gel, with Carbopol showing a stronger effect. Gel viscosity increased from approximately 623 to 1450 cps as the concentration of Carbopol increased, while HPMC K15M contributed moderately to viscosity enhancement through polymer interaction. The increase in gel viscosity may improve ocular retention time and sustain Bromfenac Sodium release at the site of administration.

Discussion: Viscosity Gel (Cps) – 3D Surface Plot

The 3D surface plot for gel viscosity demonstrates the combined effect of Carbopol (Factor A) and HPMC K15M (Factor B) on the viscosity of the Bromfenac Sodium in situ hydrogel formulation. The plot shows a gradual increase in gel viscosity with increasing concentrations of both polymers, with Carbopol exhibiting a more pronounced effect. The upward slope of the response surface indicates a positive interaction between the polymers, suggesting that higher polymer concentrations enhance gel strength and viscosity, which may improve ocular residence time and sustain drug release.

Discussion: Drug Content (%) – Counter Plot

The plot clearly demonstrates that Carbopol concentration had a significant influence on the drug content of the formulation. At lower Carbopol concentration (40 mg), the formulation exhibited higher drug content values, represented by the yellow region of the contour plot. As the concentration of Carbopol increased from 40 mg to 200 mg, the drug content gradually decreased, as indicated by the transition of colors from yellow to green and finally blue. This reduction in drug content at higher Carbopol concentrations may be attributed to the formation of a dense polymeric network, which can entrap the drug and reduce its uniform distribution within the hydrogel matrix.

Discussion: Drug Content (%) – 3D Surface Plot

The 3D surface plot illustrates the combined effect of Carbopol concentration (Factor A) and HPMC K15M concentration (Factor B) on the drug content (%) of the Bromfenac Sodium hydrogel formulation while keeping Cyclodextrin concentration (Factor C) constant at 15 mg. The surface plot clearly demonstrates that Carbopol concentration had a major influence on drug content.

The in-vitro drug release profile of Bromfenac Sodium pH-sensitive in situ hydrogel formulations (F1–F13) was evaluated over a period of 8 h at predetermined time intervals, and the results were expressed as mean ± standard deviation (n = 3). At 0 h, all formulations exhibited 0% drug release, confirming the absence of premature drug diffusion prior to exposure to the dissolution medium. The cumulative drug release profiles demonstrated a gradual and sustained increase throughout the study period, indicating controlled-release characteristics of all formulations. Among the investigated formulations, F3 exhibited the highest cumulative drug release, reaching 97.0 ± 1.25% at the end of 8 h, followed by F12 (95.5 ± 1.25%), F11 (94.8 ± 1.20%), F8 (94.3 ± 1.05%), F13 (93.5 ± 1.12%), and F7 (93.3 ± 1.00%). Formulations F4 and F9 achieved cumulative drug releases of 92.5 ± 1.12% and 92.3 ± 1.05%, respectively, whereas F1, F6, F10, F2, and F5 showed comparatively lower drug release values of 91.2 ± 1.16%, 91.0 ± 1.08%, 90.2 ± 1.16%, 90.8 ± 1.20%, and 88.8 ± 1.10%, respectively. The superior drug release observed with formulation F3 may be attributed to the optimized polymer concentration and appropriate gel network formation, which facilitated efficient hydration, swelling, and diffusion of Bromfenac Sodium from the hydrogel matrix. The balanced viscosity and gel strength of F3 likely contributed to its controlled yet enhanced drug release behavior. In comparison with the other formulations, F3 provided the most desirable release profile by achieving nearly complete drug release over 8 h while maintaining sustained-release characteristics. These findings suggest that the polymer composition used in F3 offered an optimal balance between gel integrity and drug diffusion, making it a promising formulation for Sustained ocular drug delivery.

Het Cam Test Result

To evaluate the ocular irritation potential of the Bromfenac sodium hydrogel formulation for ophthalmic application, Hen's Egg Test on Chorioallantoic Membrane (HET-CAM) was performed. The test was performed by applying the

hydrogel formulation on the chorioallantoic membrane of fertilized hen's eggs and observing the membrane for any signs of irritation such as hemorrhage, vascular lysis or coagulation within the specified observation period. The Bromfenac sodium hydrogel formulation did not show any visible signs of hemorrhage, coagulation or lysis of blood vessels during the experimental period. The blood vessels of the chorioallantoic membrane remained intact and normal throughout the study indicating non-irritant nature of the formulation to ocular tissue. The irritation score obtained from the HET-CAM test was found to be in the non-irritant category. No toxic reactions observed, which indicates that the polymers, excipients and drug incorporated in the hydrogel formulation were compatible with ocular tissues and safe for ophthalmic administration. The formulation's good ocular tolerability may also be attributed to its pH and viscosity. The HET-CAM study demonstrated that the Bromfenac sodium hydrogel formulation was safe, non-irritating and suitable for ocular drug delivery applications.

Sterility Test

Sterility testing was carried out using Fluid Thioglycollate Medium (FTM) and Soybean Casein Digest Medium (SCDM) to evaluate microbial contamination. In the FTM test, no microbial growth was observed after 14 days of incubation, confirming the absence of aerobic and anaerobic microorganisms.

Stability Study

The stability study of the optimized Bromfenac Sodium Hydrogel formulation (F3) was conducted to evaluate its physical, chemical, and performance characteristics during storage. The formulation was periodically assessed for appearance, homogeneity, phase separation, pH, viscosity, drug content, and in-vitro drug release. Table 8. Evaluation of Stability Parameters of Optimized Bromfenac Sodium Hydrogel Formulation (F3) During Stability Study.

CONCLUSION AND DISCUSSION

The present study successfully formulated and evaluated a pH-sensitive in-situ hydrogel system containing Bromfenac Sodium for ocular administration. The developed formulations demonstrated desirable physicochemical characteristics, including suitable pH, rapid gel formation, appropriate viscosity, effective spreadability, isotonicity, and consistent drug content. Preformulation investigations confirmed both drug purity and compatibility with the selected formulation components. Sustained drug release was observed during in vitro studies, with formulation F3 exhibiting the most favorable performance through an optimal balance of gel integrity and drug diffusion. Furthermore, HET-CAM evaluation verified the non-irritant nature and ocular safety of the optimized formulation. DOE-based optimization demonstrated that Carbopol concentration significantly influenced viscosity and drug-release behavior. Collectively, these findings indicate that the developed pH-sensitive in-situ hydrogel offers a viable alternative to conventional ophthalmic formulations by extending precorneal residence time, enhancing bioavailability, reducing administration frequency, and improving patient adherence. Therefore, the optimized Bromfenac Sodium in-situ hydrogel may serve as an effective and patient-friendly platform for the treatment of ocular inflammation.

ACKNOWLEDGMENTS

For the successful completion of this research project, the authors extend their sincere gratitude to Loknete Dr. J. D. Pawar College of Pharmacy, Manur (Kalwan) for providing the essential active materials, processing chemical reagents, and analytical laboratory instruments.

ABSTRACT

Software-defined networking (SDN) and autonomous networking are quickly becoming cornerstones of today's communication systems. Their appeal lies in how they handle reliability and adaptability—two things networks need more than ever. At the same time, breakthroughs in artificial intelligence, machine learning, and deep learning have given us powerful tools for predicting failures, automating recovery, and building networks that can heal themselves without human help. This survey dives into the latest AI-driven methods for fault detection, diagnosis, recovery, and network optimization in SDN and self-managing networks. We look at methods built on reinforcement learning, digital twins, orchestration frameworks, and Zero-Touch Management (ZSM). We also tackle some big challenges along the way—scalability, explain ability, security, and interoperability. Finally, we point to future research that's steering us toward networks that are not just autonomous, but truly resilient.

Keywords: Software-Defined Networking, Self-Healing Networks, Failure Prediction, Artificial Intelligence, Network Automation, Zero-Touch Management
