The rapid evolution of digital services, driven by massive cloud deployments and distributed systems, has introduced unprecedented complexity into network infrastructures. This complexity inherently increases vulnerability to faults, performance degradation, and cascading failures, making traditional resilience strategies, which often rely on redundancy and extensive manual intervention, increasingly inadequate [1]. Industries such as Industry 4.0, cyber-physical systems, and critical infrastructure demand continuous uptime, high-volume telemetry processing, and stringent reliability, necessitating a paradigm shift in network management [2], [3]. Concurrently, advancements in AI, ML, and DL have provided powerful tools for automating various aspects of network operations, including fault detection, diagnosis, and self-healing. These intelligent approaches are transforming network management from reactive to proactive, enabling systems to anticipate and mitigate issues before they impact service availability [4]. The emergence of Software-Defined Networking (SDN) has further facilitated this transformation by decoupling the control plane from the data plane, offering a centralized, global view of the network. This architectural flexibility allows for dynamic rerouting, faster recovery from disruptions, and optimized traffic management, laying a robust foundation for AI-driven automation [5].

The study organizes existing knowledge, dissect prevalent techniques and architectures, and highlight persistent challenges. Specifically, this paper offers:

- A comprehensive overview of AI-powered self-healing mechanisms in SDN and autonomous networks.
- A comparative analysis of diverse strategies for failure prediction, automatic recovery, and network optimization.
- An exploration of key learning methods, including ML, DL, and Reinforcement Learning (RL), that underpin intelligent network management.
- An identification of critical research challenges, such as scalability, explainability, interoperability, and security.
- Insights into future research directions, particularly concerning Zero-Touch Autonomous Networking and integration with emerging technologies like 6G.

By addressing these aspects, this survey seeks to provide a foundational understanding for researchers and practitioners engaged in developing the next generation of resilient and intelligent network infrastructures.

Background and Motivation

The proliferation of cloud services, 5G/6G technologies, the Internet of Things (IoT), and mission-critical applications has rendered modern networks highly dynamic and exceptionally sensitive to failures. Disruptions such as link breakages, node failures, congestion, or controller malfunctions can severely degrade service quality, violating the strict Service Level Agreements (SLAs) required by contemporary applications [6]. Traditional IP networks typically rely on distributed routing protocols for reconvergence following a failure. However, this process is often slow, cumbersome, and prone to issues like routing loops and packet loss. Furthermore, the tight coupling of control and data functions in traditional routers limits their ability to achieve global optimization, as each device operates with only a localized view of the network state [7]. SDN addresses these limitations by separating the control logic from the underlying forwarding hardware. A centralized SDN controller maintains a global view of the network topology and state, enabling intelligent, network-wide decision-making. This architecture facilitates rapid failure detection, flexible rerouting, and real-time traffic optimization, making SDN an ideal platform for implementing resilient and self-healing systems [8].

However, integrating intelligent prediction and automated recovery into SDN is not without challenges. Issues related to controller scalability, resource constraints, and maintaining Quality of Service (QoS) during dynamic reconfigurations must be carefully managed. A unified approach that seamlessly blends predictive analytics, robust recovery strategies, and continuous optimization is essential for realizing the full potential of self-healing SDN [9].

The motivation for this survey stems from the need to consolidate the fragmented literature on SDN failure management. While existing reviews often focus on isolated aspects such as either prediction or recovery—this paper provides an integrated perspective. We evaluate the primary strategies for protection, restoration, and optimization, and delineate the unresolved issues that must be addressed to achieve fully autonomous, performance-aware, and self-healing SDN environments.

Conceptual Architecture and Taxonomy of AI-Driven Self-Healing SDN

To effectively implement AI-driven self-healing capabilities in Software-Defined Networks, a well-defined conceptual architecture and a clear taxonomy of techniques are essential. This section outlines a proposed conceptual architecture and categorizes the various AI-driven self-healing techniques.

Taxonomy of AI-Driven Self-Healing Techniques

AI-driven self-healing techniques can be broadly categorized based on their underlying methodologies and applications within SDN. This taxonomy helps in understanding the diverse approaches employed for fault management and network optimization.

Comparative Analysis of AI-Driven Self-Healing Approaches

Various AI-driven methodologies have been proposed and implemented for self-healing in network environments, each with distinct advantages, limitations, and suitability for different scenarios. This section provides a comparative analysis of these approaches, drawing insights from the original document and additional research.

Quantitative Performance Comparison of AI-Based Self-Healing Techniques

The effectiveness of various AI-based self-healing techniques can be quantitatively assessed across several performance metrics, including prediction accuracy, recovery speed, scalability, and computational cost. The choice of technique often involves a trade-off between these factors, depending on the specific network environment and operational requirements.

Comparison of AI-Based Failure Prediction and Recovery Techniques

Further dissecting the approaches, it is crucial to understand the specific strengths, weaknesses, and suitability of each AI-based technique for failure prediction and recovery

Critical Discussion

The integration of AI into self-healing and autonomous networks, while promising, introduces several critical considerations that warrant in-depth discussion. These revolve around the trade-offs between accuracy and interpretability, the balance between automation and human control, and the perennial challenge of performance versus resource demands.

Accuracy vs. Interpretability

Deep learning models, renowned for their superior accuracy in complex pattern recognition, often operate as black boxes. This lack of transparency poses a significant challenge, particularly in critical network infrastructures where understanding the rationale behind an AI's decision is paramount for trust, debugging, and regulatory compliance. The observation here is that Explainable AI (XAI) is not merely a desirable feature but a necessity to bridge the gap between high accuracy and human understanding, thereby fostering confidence in AI-driven autonomous systems.

Automation vs. Control

The allure of fully autonomous networks lies in minimizing human intervention, leading to reduced operational costs and faster response times. However, relinquishing complete control to an autonomous system, especially in

critical infrastructure, carries inherent risks. An erroneous decision by an AI could have severe consequences. Therefore, maintaining a human-in-the-loop approach for validation, oversight, and intervention remains essential. This ensures that while AI automates routine tasks and provides predictive insights, ultimate control and accountability reside with human operators, particularly for high-stakes decisions.

Performance vs. Resource Demand

State-of-the-art AI models, particularly deep learning architectures, are computationally intensive, demanding substantial processing power and memory. This presents a significant hurdle for deployment in resource-constrained environments, such as edge devices or certain industrial IoT (IIoT) scenarios. The need for lighter models and distributed learning paradigms like federated learning becomes critical to enable AI-driven intelligence closer to the data source, reducing latency and optimizing resource utilization without compromising performance. This trade-off necessitates innovative approaches to model design and deployment strategies.

Failure Prediction and Recovery Mechanisms

Effective self-healing in SDN and autonomous networks hinges on robust failure prediction and efficient recovery mechanisms. This section delves into the workflow of AI-based failure prediction and outlines various recovery strategies.

Failure Prediction Workflow

AI-based failure prediction in self-healing SDN typically follows a structured workflow, enabling proactive identification and mitigation of potential network issues. This workflow generally involves several key stages:

- Data Collection and Preprocessing: Gathering diverse network telemetry data (e.g., traffic logs, device status, performance metrics, environmental data) and preparing it for AI model consumption through cleaning, normalization, and feature engineering.
- Feature Extraction and Selection: Identifying relevant features from the pre processed data that are indicative of impending failures. This often involves domain expertise and advanced statistical or ML techniques.
- Model Training: Utilizing historical data with known failure events to train AI/ML models (e.g., supervised learning, time series analysis) to recognize patterns preceding failures.
- Prediction and Anomaly Detection: Deploying the trained models to continuously monitor real-time network data, predict potential failures, and detect anomalies that deviate from normal operating behavior.
- Decision Making and Alerting: Based on predictions and anomaly detections, the system makes informed decisions about the likelihood and severity of a failure, triggering alerts or initiating recovery actions.

Recovery Strategies

Once a potential or actual failure is detected, various recovery strategies can be employed to restore network functionality and maintain service continuity. These strategies can be broadly categorized as proactive, reactive, or a hybrid approach:

- Proactive Recovery: This strategy involves anticipating failures and pre-installing backup paths or reconfiguring network resources before an actual outage occurs. This leads to faster response times and minimal service disruption. Examples include pre-computed backup paths or redundant resource allocation.
- Reactive Recovery: Triggered after a failure has occurred, this approach focuses on diagnosing the issue and then initiating corrective actions. While it might incur a brief service interruption, it typically utilizes fewer resources than proactive methods as resources are only allocated when needed.
- Hybrid Approach: Combining elements of both proactive and reactive strategies, this approach aims to leverage the benefits of both. For instance, critical network segments might employ proactive measures, while less critical areas rely on reactive recovery. This is often the most effective approach in complex, real-world systems, balancing resource utilization with resilience requirements.

Research Gaps

Despite significant advancements in AI-driven self-healing for SDN and autonomous networks, several critical research gaps and open challenges remain. Addressing these will be crucial for the widespread adoption and full realization of truly intelligent and resilient network infrastructures. The overarching challenge remains the effective implementation of AI-powered self-healing in real-world, large-scale, and resource-constrained environments, while ensuring security, explain ability, and seamless integration with existing and emerging network architectures. Future breakthroughs are anticipated in these critical areas.

CONCLUSION

This survey has provided a comprehensive overview of AI-driven self-healing and failure prediction in Software-Defined Networking and autonomous networks. We have highlighted the increasing complexity of modern network infrastructures and the limitations of traditional management approaches, underscoring the necessity for intelligent, automated solutions. The architectural flexibility of SDN, combined with advancements in AI, ML, and DL, offers a powerful paradigm for developing networks that can proactively detect, diagnose, and recover from faults. The survey analyzed various AI-driven methodologies, including those based on reinforcement learning, knowledge-driven systems, and hybrid models, comparing their strengths, weaknesses, and suitability across different network environments. Critical discussions on the trade-offs between accuracy and interpretability, automation and human control, and performance versus resource demands have shed light on the inherent complexities and ongoing challenges in this field. Furthermore, we have identified key research gaps, such as scalability, data quality, security, and standardization, and proposed future directions including federated learning, explainable AI, integration with 6G and edge computing, and the development of digital twins. Addressing these areas will be crucial for advancing towards truly resilient, autonomous, and intelligent network management systems that can meet the demands of future communication landscapes.

Table 1: Key motivations for an integrated survey on AI-driven SDN failure management.

Driver	Brief Explanation
Limitations of Traditional Routing	Slow, localized reconvergence, susceptibility to routing loops, and poor global optimization capabilities.
Demand for Fast, Reliable Recovery	Necessity for carrier-grade availability, adherence to strict SLAs, and support for mission-critical applications.
Centralized SDN Control	The global network view provided by SDN controllers enables flexible, intelligent failure detection and rapid restoration.
Rise of AI/ML and Predictive Analytics	ML techniques significantly enhance the accuracy of failure prediction and the adaptability of recovery mechanisms.
Need for an Integrated Survey	Existing literature often treats prediction, recovery, and optimization in isolation; a unified review is required to address the holistic self-healing process.

Table 2: Peak-level scope of surveyed self-healing research

Aspect	Brief description	Citations
Domains	Cloud, CPS, Industry 4.0, buildings, PV, transport	[9], [10],[13], [12],[14], [15], [16], [19], [22], [23]
Core tasks	Fault detection, diagnosis, recovery, optimization	[10],[13], [12],[14], [15], [16], [19], [23]
Key enablers	ML, DL, XAI, digital twins orchestration	[10],[11], [13], [12],[14], [16], [3], [20], [21], [26], [25]
Gaps	Data scarcity, evaluation, explain ability, integration	[10],[11], [12],[12],[14], [15], [16],[17], [23]

Table 3.Comparative Analysis of Existing AI-Driven Self-Healing Approaches

Methodology / Paradigm	Typical AI / ML Algorithms Used	Main Merits for Automation / Self-healing	Key Limitations / Challenges	Critical Factors to Include in Survey	Citations
SDN/NFV-based closed-loop automation (MAPE-K, SON, NI)	RL (Q-learning, Deep RL), supervised models for anomaly/fault prediction, heuristic/optimization for scaling	Centralized programmability, fast reconfiguration, supports self-optimization and self-healing via monitor–analyze–plan–execute loops [42],[69] ,[50],[51]	Controller scalability, robustness and security issues; integration with legacy devices; data/telemetry quality [50]	Control-/data-plane split orchestration layer, telemetry sources, latency constraints, controller redundancy, fault coverage, interoperability	([42,69]; [44]; [49]; [50]; [51]; Ahmad & Mir, 2020)
Knowledge-driven autonomic architectures (ETSI GANA, autonomic/intent-based networking)	Rule-based reasoning, knowledge graphs, case-based reasoning; ML often used for policy refinement	Human policies encoded as high-level "intents"; hierarchical decision elements enable multi-level self-configuration and self-healing [42,69],[51], [54],[60]	Knowledge modeling effort is high; difficulty keeping knowledge base consistent; limited learning if rules are static	Abstraction levels (node/network), policy/intent language, conflict resolution, verification, operator override, explainability	([42,69]; [44]; [51]; [54],[60])
AI-driven network automation (general IP/enterprise, cloud, SD-WAN/SASE)	Supervised learning (ANN, SVM, RF), unsupervised anomaly detection, RL for routing/TE and self-healing; federated learning at edge	Improved routing/TE, predictive fault detection, automated configuration and policy enforcement, reduced OPEX, energy-aware optimization [45] [46] [7] [55] [58]	High data/compute requirements; trustworthiness and explainability of AI decisions; model drift; security/privacy of telemetry [45] [46] [7] [55] [58])	Data pipeline (volume, labeling, imbalance), training/inference placement (edge/cloud), KPI definitions, human-in-the-loop , robustness to adversarial input	([42,69]; [45]; [46]; [49]; [7]; [55]; [53]; [58])
ML-based self-healing in cellular/IIoT/O-RAN/SON	Fault classification (SVM, RF), deep learning, RL, meta-learning ensembles; cost-sensitive and imbalance-aware methods	Automatic detection, diagnosis and recovery from radio/link faults; improved QoS/QoE; supports large-scale dense networks [45] [48]	Data imbalance, scarcity of labeled fault data, multi-source data fusion, latency of learning loops, generalization across deployments [48] [49] [53]	Fault taxonomy, data sources (KPIs, logs), reaction time vs. accuracy trade-off, cost-sensitive metrics, transfer learning, safety constraints for actions	([45]; [48]; [49]; [53])

Methodology / Paradigm	Typical AI / ML Algorithms Used	Main Merits for Automation / Self-healing	Key Limitations / Challenges	Critical Factors to Include in Survey	Citations
		[49] [53]			
Industrial / IIoT network automation toward Industry 4.0/5.0	Predictive analytics, RL, deep learning for scheduling/resource allocation, anomaly detection	Handles strict latency/reliability requirements, supports human-robot collaboration and massive IIoT; enables proactive maintenance [42],[69],[45]	Heterogeneous devices and protocols, legacy integration, safety-critical constraints, limited compute at edge nodes	Deterministic latency, reliability targets, edge–cloud split, standardization status, cyber-physical safety requirements	([42,69]; [45])
Template- / tool-based configuration automation (e.g., Nornir, Jinja, Ansible-like tools)	Usually rule-based; may integrate simple ML for anomaly/rollback triggers	Large reduction in manual effort and errors; consistent multi-vendor configuration; good entry point for automation maturity [47]; [51]; [52]	Not inherently "intelligent"; limited to scripted logic; still relies on humans for diagnosis and policy design	Inventory modeling, idempotent templates, change-control and rollback strategy, integration with CI/CD and logging, operator skills	([47]; [51]; [52])
Security automation for networks (policy synthesis, automatic NSF composition/config)	Optimization (ILP), model checking, ML for threat detection (NNs, anomaly detection, ensemble methods)	Automatic generation and validation of firewall/VPN/ACL policies; faster reaction to attacks; fewer configuration errors [43]; [44]; [46]; [52]; [55]	Complexity and scalability of policy synthesis; multi-domain consistency; exposure to new automation-specific attack surfaces [43]; [44]; [55]	Correctness and optimality guarantees, coverage of security functions, scalability (rules/devices), integration with SIEM/SOAR, compliance mapping	([43]; [44]; [46]; [52]; [55])
Knowledge-/data-driven self-healing frameworks for autonomous networks	Hybrid: knowledge-driven diagnosis + ML-based prediction and policy selection	Provides reusable patterns for self-healing loops; supports heterogeneous failures; moves toward Level-5 autonomous networks [54],[60]	Designing generic yet effective knowledge schemas; validating self-healing actions under diverse scenarios	Failure ontologies, feedback loops, evaluation on real incidents, interaction with human operators, multi-domain scope	([54],[60])

Table 4. Quantitative Performance Comparison of AI-Based Self-Healing Techniques

Technique	Prediction Accuracy	Recovery Speed	Scalability	Computational Cost	Suitable Environment
Rule-Based Systems	Medium	Fast	Low	Low	Small networks
Machine Learning	High	Medium	Medium	Medium	Enterprise SDN
Deep Learning	Very High	High	High	High	Large-scale cloud networks
Reinforcement Learning	High	Adaptive	High	Very High	Dynamic autonomous networks
Hybrid AI Models	Very High	Very High	High	High	Real-time self-healing systems

Table 5. Comparison of AI-Based Failure Prediction and Recovery Techniques

Approach	Strength	Weakness	Suitability
Rule-Based Systems	Simple and interpretable	Not adaptive	Small networks
ML-Based Prediction	Accurate detection	Data dependency	Medium-scale networks
Deep Learning	High accuracy	High computation cost	Large-scale networks
Reinforcement Learning	Adaptive decision-making	Slow training	Dynamic environments
Hybrid Models	Balanced performance	Complex design	Real-world deployment

Table 6. Research Gap

Gap Area	Typical Missing Pieces	Key Sources
Heterogeneous, real-world validity	Cross-domain test beds, multi-vendor evaluation	[59], [53], [66], [45], [42], [69], [72]
Resource-aware real-time AI	Lightweight, adaptive, energy-efficient models	[59], [53], [67], [45], [71], [77]
Secure, explainable ZTA/ZSM loops	Formal guarantees, adversarial robustness, auditability	[61], [46], [66], [67], [43]
Unified autonomous frameworks	Standardized patterns (KSHP, GANA, O-RAN) with AI at scale	[54], [60], [66], [45], [42], [69], [76]

ABSTRACT

This chapter discusses the transformational role of AI leadership in Indian higher education institutions in building inclusive learning cultures that will deepen human capital over a lifetime. It contends that higher education leaders must focus AI initiatives not on automation but on clarity of vision and purpose around equity, multilingualism, faculty, ethical governance, and lifelong employability, which are where the strategic values amid the exigencies of artificial intelligence will lie. Based on what we know of the India-based policy landscape, global directions on AI in education, and the leadership scholarship, the chapter provides a functional framework for institutional leaders. The framework links the transformational leadership behaviours to components of (1) enacting an inclusive digital infrastructure, (2) curriculum redesign, (3) responsible data governance, and (4) ecosystem partnerships. In doing so, the chapter rates AI governance as a key variable that will determine how adaptive, just and ready-for-the-future Indian higher education can be and concludes with some lessons from the AI-related discourse to reform the relationship between human beings in general and 'AI' in particular, treating the latter as one of the possible futures of human-centered public good and not as a narrow techno-ethical intervention.

Keywords: Artificial intelligence, transformational leadership, Indian higher education, inclusive learning culture, lifelong learning, human capital development**.**

INTRODUCTION

Indian higher education is at a unique point in its history. On the one hand, the sector is growing in size and breadth of its student body, and, at the same time, it is being challenged by technological disruption at an unprecedented rate. Artificial Intelligence (AI) is now ascribed as a promise to every major institutional aspiration: personalised learning, administrative efficiency, academic analytics, multilingual access, employability enhancement, research productivity, and micro-credentialed lifelong learning. However, simply implementing technology does not enable an organisation to evolve to a new level. Leadership does. In higher ed, the question is not whether we can buy or pilot these tools, but whether leaders can model organisational cultures that will, in the longer term, employ AI to deepen inclusion, broaden opportunity, and reinforce human agency. In touch with this question, especially in India, since scale meets inequality here.

The higher education system is large, socially heterogeneous, and geographically unequal. It varies considerably, from large, well-resourced metropolitan universities to small or semi-urban colleges that face enormous infrastructure constraints. In such a context, AI may act as a bridge or a gaping chasm. Without ethical vision, pedagogical redesign, or equitable planning, it can exacerbate inequities. However, if managed skilfully, it can facilitate access, flexibility, multilingualism, and disability support, and provide better pathways to lifelong learning and employment. The chapter argues that if Indian higher education institutions are to convert technological possibilities into socially inclusive, ethically governed, lifelong human capital development, transformational AI leadership is called for, in which humans take charge of AI, not the other way around. Transformational AI leadership, as used here, refers to a mode of institutional leadership that can articulate a human-centred vision of AI, articulate values, drive engagement around that vision and those values, spur pedagogical and organisational experimentation, and respond to the diverse needs of learners, faculty, and communities. Such an approach is in stark contrast with compliance-only or procurement-only models. It operates through culture, not just through tools.The discussion is divided into six general movements. It begins with a literature review on transformational and inclusive leadership and learning culture relevant for AI-enabled higher education. Second, it places the conversation within the landscape of higher education in India and the public policy framework. Third, it articulates a conceptual leadership framework for transformational AI. Fourth, it defines leadership levers and an implementation roadmap for institutions to use strategically. Fifth, it deals with risks and governance tensions. Lastly, it comments on the consequences of AI leadership for human capital development over the course of a human life.

Transformational Leadership, Inclusion, and Learning Culture

Transformational leadership is as powerful a lens for making sense of educational change as any because it shows how leaders take organisations through space in the human enterprise, past the mere administration of routine, toward mission-propelled renewal. It is most commonly connected with idealised influence, inspirational motivation, intellectual stimulation and individual consideration. But these dimensions matter deeply in higher education, which depends on trust, shared governance, professional autonomy, and collaborative legitimacy among its institutional members. Universities and colleges seldom find their way to success in change. Please note: They change when people understand what they are participating in and the process they are part of. In higher education, the value of transformational leadership stems from its compatibility with the attributes of academic professionalism. Transformational leadership works (in contrast to purely transactional models that emphasise compliance, outputs, and incentives) to create a shared purpose and collective efficacy. This is especially true during times of technological change. The bulk of institutional opposition to AI is not just mere technical unfamiliarity. This too is intertwined with moral ambiguity, pedagogical anxiety, anxiety about compromised academic discernment, and anxiety about professional identity. This means leaders need to do more than green light the use of software; they have to shape the sense making of why and how AI should be adopted. But transformational leadership is not enough if it is not purposefully inclusive. The pace of diversity has outstripped many organisations' ability to foster true belonging. So

inclusive leadership focuses less on participation than on access, less on climate than on representation, and less on accommodation than on structural redesign. To build such spaces means practising inclusive leadership in our higher education contexts, creating intentional spaces where the dignity, recognition, support, and voice of historically marginalised learners and staff are integrated into institutional life. And it requires leaders to prepare institutions not to react to overt expressions of exclusion, but to examine and dismantle latent systems of oppression. Learning culture bridges transformational and inclusive leadership. A learning culture might be defined as the norms, expectations, routines, and relationships through which individuals and groups grow their capacity to acquire, evaluate, share and use knowledge. A strong learning culture is evident in higher education when inquiry is valued, mistakes are viewed as a part of the process of honing improvement, professional development is prized, and assessment drives higher-order thinking. AI was an approach that made this culture more important. Schools that only try to ban AI will fail to prepare students for an AI-rich world. On the other hand, institutions that foster critical AI literacy, ethical evaluation, team-based investigations, and the restructuring of assessment will likely graduate students who are better prepared to thrive and build more resilient academic communities.Thus, transformational AI leadership in this chapter describes a linking of three dimensions that all too often remain separated: transformational change, inclusive culture, and responsible AI integration. It is not a glorification of AI as a being acting on its own. It is a position that leads with human agency, justice, and long-term capacity as the guiding principles for the future of technology. In that way, AI leadership in higher education is more of a cultural project with technical components than a technical project with cultural externalities.

Why India Needs a Distinctive Response

The discussion acquires both urgency and specificity from the context of higher education in India. This is a very large, internally differentiated, developmentally important system. It consists of a central university, a state university, a private university, a deemed university / deemed to be university, an autonomous college, an affiliated college, a technical institute, an open university and a stand-alone professional institution. This diversity implies that AI transformation cannot happen following a single institutional template. Leadership models should reflect the missions, the demographics of the students served, the region's ecologies of language, and local realities and resource conditions. There is already a substantial policy infrastructure in place for this transformation. The NEP 2020 emphasises multidisciplinary, equitable, and inclusive education; lifelong learning; digital and Online education; adult learning; Indian languages; and technology in tandem. It views technology as a means to improve access, providing services that support learners with disabilities and eliminating geographical and language barriers. Therefore, AI leadership in higher education in India cannot be envisioned as a new-age extra. Instead, it ought to be seen as one of the emergent governance challenges in a broader educational transformation that is happening regardless. In practise, India has significantly expanded its digital learning ecosystem. With the new initiatives launched in the past few years, including SWAYAM, SWAYAM Plus, SAMARTH, NEFT ecosystem, and the multilingual digital tools, online learning and digital administration of education are no longer marginal. These policies are now a part of the institutional environment within which AI decisions will be made. While this development opens opportunities, it also raises the stakes. Digital infrastructure that enhances educational equity outcomes is not a given; it must be paired with capable and inclusive leadership at the institutional level to have that effect.

Recent years have clarified the momentum of AI policy. At the national level, AI is now framed not just as a technological innovation, but also as a strategic capability for education, connected to teaching and learning, workforce preparedness, and research. This is significant and also explains why coordination now matters more than experimentation. Those institutions that cannot build leadership capacity will have difficulty translating national initiatives into local advantage. In contrast, institutions that invest in leadership, faculty development, and inclusive design will likely convert policy momentum into lasting institutional improvement. But there are also structural risks in the Indian context. Inaccessibility due to uneven connectivity, device costs, faculty preparedness discrimination, the urban-rural divide, English domination, and variation across disciplines could contribute to AI-driven exclusion, as well as to unequally distributed resources, rather than to its negation.

AI in Higher Education: From Tool Adoption to Institutional Capability

Global higher education systems are racing fast to the shores of AI use, but not necessarily in an orderly fashion. Despite the shift, many institutional responses remain piecemeal, hyper-focused on generative AI regulations or limited to concerns about identifying harmful content. These are reasonable tactics in the short run, but short-term solutions are no solutions at all. The more profound question is not if students should access AI tools. More profound concerns the capacities, values, habits, and possibilities that institutions need to develop for an AI-enriched society. That shift is similarly decisive for Indian higher education because of the dual demands of the country's developmental agenda—elite innovation and broad-based capability formation. AI is relevant beyond computer science, computer engineering, and the myriad ways they intersect, but also to agriculture, law, healthcare, business, teacher education, languages, design, public policy, and the humanities. Unless AI leadership extends beyond IT and data science departments, higher ed will reproduce the very narrow specialisation rather than a multidisciplinary transformation. In sharp contrast, transformational AI leadership treats AI as an institutional capability that cuts across disciplines and learner groups, with differentiated relevance for each. The argument is more apparent when framed in terms of lifelong human capital formation. Whereas many narrowly conceptualise human capital in terms of employability or income, it should be interpreted more broadly in relation to higher education as the cumulative development of knowledge, adaptive skills, ethical judgment, creativity, collaboration, technological fluency, linguistic capability, and civic agency across the lifespan. These characters are then relevant to personalised learning and lifelong human capital development; hence, institutions need, or even are required to, cater to full-time traditional students as well as working adults, returning learners, re-skillers, micro-credential learners, and community-facing learners. This perspective is so closely aligned with the reality of today's labour markets. Artificial Intelligence is changing work, changing the skills required, and emphasising the need for continuous learning. Institutions cannot think that one-and-done preparation will do it in this environment. Graduates will likely face multiple transitions over time and rapidly changing expectations of their occupations or positions. Hence, institutions that build curiosity, self-learning, ethical distinction, and digital adaptability provide a non-perishable value more than institutions that focus on a temporary solution of platform familiarity. The key takeaway is that AI adoption should be viewed as a capability-building effort and not a technology deployment effort. The tools you choose are important, but your institutional capability is crucial. Diploma level: 6, which encompasses ethical governance, multilingual access, inclusive pedagogy, faculty confidence, critical AI literacy, and redesign assessment willingness. AI is just surface-level without these dimensions. With them, AI has the potential to be an engine for educational renaissance.

A Conceptual Framework for Transformational AI Leadership

This framework views transformational AI leadership as a system of mutually reinforcing institutional practices, rather than as a single characteristic of leadership. We use AI tools as inputs and expect direct outcomes. They are mediated by culture. An AI Vision Based On Education In Purpose Brought At First By Leadership. Its next step is to create enablers such as faculty development, student assistance, digital and language accessibility, ethical policies,and inter-sector partnerships. They shape learning culture by affecting trust, willingness to experiment, collaboration, and readiness to modify pedagogy and assessment. That is when human capital outcomes become durable.

Visionary Human-Centred AI Strategy

The journey of wise AI leadership transformation begins with narrative. It's now the responsibility of leaders to explain why AI is a relevant part of the mission of an institution and why using AI must always and only take a back seat to human development, and not to serve it, but take the lead. An AI narrative that convinces the institution will have to link AI, not technological wizardry, to student success, inclusive and participatory, multilingual, faculty augmentation, relevance to communities, and future work readiness. In the absence of such vision, AI projects suffer from fragmentation, become vendor (product)-driven, superficial, or compliance-oriented. This empowers AI adoption to be directed by mission. A visionary strategy should also define what an institution will not do. Not every AI tool meets educational standards, and not every efficiency gain merits adoption. Hence, a human-centric strategy

is a selective judgment. It queries whether AI serves learning, whether it broadens rather than constricts participation, whether it respects privacy, and whether it empowers faculty and students to exercise critical agency. Strategic ambition is only half the equation; the other half includes strategic restraint.

Inclusive Governance and Ethical Stewardship

Leaders need to establish governance committees with representation from faculty, students, technologists, librarians, legal experts, disability services experts, and, when appropriate, community voices. Governance should clarify what constitutes an acceptable use, what transparency requirements exist, what audit standards apply, what procurement rules are, how bias will be reviewed, what protections for privacy are in place, and what processes for appeal or revision there is (e.g. if you have to replace someone whose life it would destroy to be banned from receiving services related to their work). Ethical Governance is not a Bureaucratic Fragment. This is a condition for the credibility of AI use in education. Policy is seen as a rehearsed process in an inclusive governance model. No guide to AI should be marketed as a definitive rulebook that's set in stone. Due to the quick changes in tools, risks, and ways of working, governance should be an ongoing system of guidance, tracking, reflection, and adjustment. Providing this impression of transparency and trust also makes policy more relevant to the realities of teaching and learning.

Faculty Capability and Professional Learning

A successful AI strategy in higher education will not stop at the margins of faculty development. Facilitating tools alone are insufficient; we need broader support for redesigning courses, assessing AI outputs, embedding AI literacy instruction, developing discipline-sensitive assessments, and reassuring faculty that academic integrity can be salvaged without OMNEC. This will take time and investment: in incentives, mentoring, experimentation, and communities of practice. Faculty development should be an institutional obligation, not an elective benefit. Peer Mentoring, Micro-certifications, Discipline-based Workshops, Collaborative Labs, Faculty Learning Communities. Now, the larger goal here is not technology-related compliance. Pedagogical confidence and professional judgment in an AI-infused environment.

Designing for Accessibility, Inclusion, and Multilinguality

Exclusion will reproduce with Indian AI leadership if it ignores language, disability and digital disparity. While building on multilingual tools, online and open-distance pathways, and digital public platforms, leaders need to situate these foundations within the actual design of the student experience. That should translate into affordable accessibility, mobile-first user interfaces wherever feasible, accessible content standards, assistive technologies, multimodal delivery and the use of Indian languages for all teaching and student services. Rather, inclusion has to be engineered into infrastructure instead of being tagged on afterwards. This principle is especially critical for first-gen learners, regional students, students with disabilities, and learners who work, as flexible access enables their participation. If these learners face AI-optimised systems designed around high bandwidth, English literacy or uninterrupted access to devices, then the promise of digital innovation will become the next exclusionary device.

Curriculum, Assessment, and Credential Innovation

AI leadership should focus not only on operational efficiency but also on curricular transformation. AI literacy outcomes should be cross-disciplinary, not just within technical programmes, given AI's pervasiveness. There are skills that students should gain to understand how AI systems work, how to interrogate their outputs, how to engage with AI as a responsible agent, and how to Craft Machine Input and Output with Human Judgment. This is to define AI literacy as a civic and professional competence rather than a technical specialisation. Assessment must also shift. If institutions assess through recall-based or product-only methods, they will fail to distinguish between shallow output and authentic learning. Types of tasks also matter, and we should see less writing in exams and a wider variety of assessment designs, such as reflective writing, oral defence, process documentation, collaborative inquiry, local-context application, iterative drafts, and higher-order analysis. By redesign, academic integrity becomes more significant, as learning is visible itself. The same goes for credential innovation, which is relevant to lifelong learning as well. Increasing alignment of degree programmes with stackable pathways, short learning modules, continuing

education and flexible recognition systems. Institutions can then respond to the reality of up-skilling recall when learners return to re-skill, change careers, or upgrade modules rather than following a traditional one-way linear path.

Human Capital Development through Ecosystem Partnerships

Transformational AI Maestros are externally facing. Institutions must partner with industry, government, civil society, local communities, and tech partners to develop internships, apprenticeship pathways, research collaborations, localised AI applications, innovation hubs, and community problem-solving opportunities. In the Indian context, this sort of partnership can help link higher education to employability and foster connections with regional development and social inclusion. Yet partnerships need to be regulated well. They should serve the purpose of learning, not the vendor's agenda. They must be able to bargain for access, language support, student safeguards, transparency and sustained legacy value. Instead of scale only, partnership quality should be measured by who benefits through it and whether we are creating new opportunity structures for underserved learners.

Strategic Levers for Institutional Leaders

The above framework suggests several tactical leadership levers. 1. Institutions require a mission-driven AI strategy. Let's question why we are adopting an AI, for whom our AI is, and what educational problem it is going to solve. Without clear answers, silver-bullet adoption and osmosis-like experimentation become far more common than they should be.Second, institutions need balanced governance. Establish AI governance groups comprising a diverse range of stakeholders, empowered to review use cases, procurement decisions, and emerging risks. These and similar structures enable organisations to journey from reactive crisis response to strategic, evidence-based governance. Third, faculty development needs to be viewed as a strong backbone. Faster than in people who need to interpret, adapt and humanise these platforms —opting to invest in the institution rather than in the institution. This is a strategic mistake. For sustainable change, software is less important than confident, capable teachers. Fourth, nurture a student-friendly infrastructure around AI usage. Such guidance includes their responsible use, clarity in writing assistance, advisory support, accessible reporting systems, and discipline-sensitive guidance. Students need more than rules. They require structured experiences that can help them develop competence and confidence. Fifth, leadership teams require fancier as well as evaluated monitors. It might be tempting to measure more operationally — how many tools licensed, how many pilots launched, how many dashboards deployed, etc. — but these are merely a starting point at best. There are also indicators of accessibility and inclusion, prepared faculty, confident learners, assessments, students' learning progress, and the employability relevance institutions need. In the absence of such evidence, leaders risk mistaking digital activity for educational progress.

Building Inclusive Learning Cultures

The chapter makes the case that adopting an inclusive learning culture is what actually translates AI leadership into lifelong human capital development. A learning culture that embodies this inclusiveness is one in which individuals from all identities can participate meaningfully in knowledge creation, feel psychologically safe enough to ask questions, take intellectual risks, and access the scaffolding needed to endure and flourish. This culture must tackle not just interpersonal climate but also language barriers, asymmetric digital savviness, accessibility for the disabled, gendered assumptions, social stratification, hidden curriculum, and the city-village divide in Indian higher education. These barriers may be exacerbated or softened by AI. When deployed badly, it may further advantage students who already have reliable connectivity, good English language skills, devices and confidence in using digital systems. It could likewise normalise the lack of transparent scoring, over-automation, and passive acceptance of machine output. Nonetheless, when successfully deployed, AI has the potential to assist with translation, personalised learning, formative feedback, administrative simplification, adaptive support, and expanding university access to learning opportunities. It is not about the technology per se, but rather about the choices in access, pedagogy, governance, and leadership support. Thus, transformational AI leaders must develop many of the critical cultural conditions. They have to establish trust by being clear, consulting people, and using data transparently. They have to foster experimentation by providing safe spaces for learning and experimentation. It is to encourage critical

use rather than dependency, and this can only be done by teaching more advanced levels of questioning, verification, and interpretation. We must build belonging into our institutional culture, through language resources, accessibility measures, mentorship, and visible markers of student identity and diversity. They also need to make improvements visible by sharing evidence, transparently reviewing quality, and celebrating best practices. For example, the question of academic integrity highlights this type of cultural challenge. For example, many institutions react to AI with a defensive mindset focused on detection and penalties. Concerns about misuse are valid, but a purely prohibitive response is insufficient. The most powerful response is to change your assessments. AI seldom replicates real learning when assignments reward process, reflection, oral explanation, critique, local application, and iterative revision. The best are not just the cops on those who stray; they reimagine learning to render integrity pedagogically salient.

Lifelong Human Capital Development

It is fine to criticise the language of human capital for reducing education to labour-market utility. That particular criticism is powerful, but it also doesn't mean that we need to throw this idea away. Instead, the realm can be redefined in a wider democratic sense. Lifelong human capital development, as it is defined here, is the incremental development of capabilities that allow humans to successfully engage in work, society, and learning over time in a productive, ethical, creative, and adaptive manner. This broad understanding is significant in the context of an AI transition, given that labour markets are increasingly brittle, less linear, and highly fluid in terms of skills. The new era of graduates will require not only discipline-specific knowledge but also multidisciplinary systems of reasonable, continuous learning, critical diagnostic understanding, stakeholder processes, collaborative action across many contexts, norms for judgment under uncertainty, and ethical approaches to both. Schools that nurture these skills are preparing students not just for their first job, but for a lifetime of changes ahead. This means four big leadership promises for India. The first is an equitable future-readiness. That kind of AI-related capability is not going to happen in an elite set of institutions that already serve privileged students. If national development is the goal, then all state institutions, affiliated colleges, small towns and low-learners must be equipped with AI literacy, digital dexterity and adaptive skills.The second pledge is that you are flexible to participate. Lifelong learning needs: modularity, blended access, online and open-distance, pathways; stackable credentials; recognition of prior learning. They must be linked by leadership to productive learner support rather than relegated to compliance exercises or recruitment strategies—commitment no 3: Multilingual and contextual relevance. Therefore, the approach to learning design for human capital development in a diverse country should not be tailored only to English-medium, metro-centric, and standardised learning design. This opens avenues for broader inclusion and contextualization of knowledge through AI-based translation and indigenous content creation, particularly for disciplines that are more community- and local-context-based—the fourth of these commitments: Employability with Integrity. And there is an even broader definition — in my opinion, AI-ready graduates are not just users of digital tools. They need to understand when not to trust them, how to detect bias, how to safeguard privacy, how to ensure efficiency—and how to reconcile the trade-off between the two, too. Thus, human capital in the age of AI is as much a matter of morals as it is of technical finesse.

An Implementation Roadmap for Indian HEIs

We need a practical roadmap because institutional leaders often agree with the general principles, but the sequencing makes little sense. A phased approach can help. The first phase is readiness. Sites need to set a common goal and get a baseline of where they are. The One phase. This includes examining infrastructure, device accessibility, language barriers, accessibility needs, educator attitudes, student readiness, disciplinary variances, and policy voids. Do not assume readiness from aspiration alone | Leaders know not to assume readiness from aspiration alone. The two phases are Governance and Sensibilization. Here are some steps institutions should take:Set up cross-functional AI governance groups, release initial guidance and establish faculty and student AI literacy initiatives. At this stage, the most productive tone is one that is permissive yet limited, delineating boundary conditions for privacy, integrity, transparency, and accountability while still facilitating experimentation and pedagogical conversation. The third phase is integrating pedagogically. They can start piloting AI-supported tutoring, multilingual course support,

student advising, accessibility support, formative feedback systems, and discipline-based curricular innovation. Rather than big symbolic launches, which yield poorer institutional learning and higher risk, it is better to run small, well-evaluated pilots. The fourth phase is scaling the ecosystem. When the support systems of governance and culture are stronger, institutions can deepen their partnerships with employers, government platforms, edtech organisations, incubators, and community actors. At this stage, the principal leadership challenge is indeed inclusion. This means that scaling should not only help those learners who are already part of the network. Data needs to be collected and analysed by institutions on who is benefiting and who is being left behind.

Risks and Governance Tensions

Any account of AI leadership worth taking seriously has to push back against the boosterism. There are genuine dangers with AI in higher education. Algorithmic inequity is one of them, especially when tools are trained on biased data or optimised with assumptions about the dominant language. A second is the loss of privacy when institutions use third-party systems that lack adequate protections for consent, storage, use, and retention of student data. Another third is called automation bias, where staff or students place too much trust in system outputs and inappropriately defer judgment. The fourth risk is pedagogical de-skilling. Excessive reliance by institutions on summaries, feedback, or surveillance systems generated through tools may erode the professional judgment integral to good teaching. The fifth is platform dependency: institutional autonomy is at risk of being subject to vendor priorities and opaque updates. A sixth would be cultural parochialism, whereby AI systems favour generic, English-dominant outputs to the detriment of Indian languages, indigenous knowledge, and contextual reasoning. The political risk: Digital visibility is not equivalent to a quality education. Modernisation by dashboards, analytics, and automation can create the illusion of improvement in teaching and learning without increasing their fundamentals. Therefore, leaders should ask over and over again, What is the educational problem that you are solving? For whom? By what evidence? At what ethical cost? These questions do not stand in the way of an innovation. They are the foundations for responsible innovation. So, it should be dialogic, not bureaucratic, to make governance responsible. Students, faculty, and professional staff should have opportunities to challenge AI decisions, voice concerns, and propose changes. What should be examined in procurement processes is not a vague promise of effectiveness, but the efficiency of determining accessibility, explainability, auditability, language, and privacy architecture. And institutions that reinforce that sort of governance habit are best positioned to keep the public trust.

Implications for Leadership Practice

Several practical implications follow from the argument of this chapter. So donengeiracomo grant ate institutional hegsoulds when heads frame work heads interface numbly the of a not stylestrumentalastic, not wisepestoplication explication as strategic culture choristrant like of avoidork, fungible as dirential piece outlingheads as rather formupountheym to as regincipalse me strongereliant. Vice-chancellors, Directors, Deans, and Principals need to take ownership of the educational narrative, authorise cross-functional governance, and ensure inclusive metrics are present in all institutional planning at conception. Middle leaders are especially important. More often, academic policy is translated from a broader policy into local academic practice through the work of department heads, programme co-coordinators, librarians, teaching and learning centre professionals and quality-assurance professionals. Thus, institutions should treat them as change agents to be invested in, rather than assume that the transformation will trickle down. Leadership development for this cohort may be as important as your high-level strategy documents. Faculty leaders should receive support to become designers of AI-critical pedagogy rather than mere consumers of technological tools. This demands recognition, responsiveness to workload, mentoring, peer exchange, and communities of practice. Student leadership matters as well. Learners should be treated as partners in policy formation, orientation design, and feedback systems, rather than as objects of suspicion,to make AI literacy and responsible governance more credible. Policy actors must build on existing use-case efforts and ensure that AI is embedded in broader system-level ambitions around access, equity, skilling, multilingualism, and digital public infrastructure. India has a richly populated policy ecology. Institutional coherence, implementation capacity and adaptation across types and contexts are the next challenges.

CONCLUSION

Artificial intelligence is the new strategic environment of Indian higher education, but its educational value will depend less on technical sophistication than on the quality of leadership. What Indian institutions need are transformational AI leaders: leaders who are visionary but not deterministic; innovative but not exclusionary; and ambitious but not at the cost of human dignity. This type of leadership recognises that while AI can enhance student course performance, faculty readiness, research, multilingualism, workforce learnability, and lifelong learning, it can do so only within institutions that foster inclusive learning cultures and ethical governance structures. Given that relevant policy, digital infrastructure, and ecosystem initiatives are already taking shape in India, the country is well-positioned to advance this agenda. The current challenge is institutional leadership at a level capable of aligning these assets with mission, culture, pedagogy, and justice. The most profound implication of the chapter is a simple one. AI in Indian Higher Education: It Should Not Be the Future of AI Be Framed As Machine Replacement. It needs to be contextualised as human augmentation. When leaders centre inclusion, multilingual access, faculty learning, assessment redesign, and ethical stewardship in AI strategy, they do more than retool institutions. In a world that will require more intelligence than we could ever need and a world that needs justice more than we ever did, they cultivate cultures that, in the long term, will sustain human capital development.

ABSTRACT

DM, especially Type 1 and residents of Type 2 type, requires regular and efficient insulin administration. Women using traditional delivery routes such as subcutaneous injections sometimes cause discomfort and non-adherence to patients. Ionic liquid (IL)-based transdermal delivery systems are outlined as a potential competitor to the current fresh development. These systems utilize the properties of ILs that are specific to promote the permeability of the skin and facilitation of non-invasive delivery of insulin. This review will explore the mechanisms, formulations, and clinical implications of transdermal systems that are based on IL in the management of diabetes.

Keywords: Diabetes, Transdermal DDS, Ionic liquid Antidiabetic drug, Skin permeability.

INTRODUCTION

Diabetes mellitus (DM) is a non-resolving hyperglycemia that affects the metabolism as a result of a failure in the secretion of insulin, its action, or both. It is among the most pressing issues in international health of the 21 st century. Today, the International Diabetes Federation (IDF, 2023) estimates more than 537 million adults with diabetes in the world and the number could reach 783 million by 2045. Among the factors contributing to the increasing rate of incidence to alarming rates are sedentary lifestyles, urbanization, obesity and genetic predisposition. Both Type 1 and Type 2 diabetes are linked to a growing morbidity and mortality cost in the name of cardiovascular disease, neuropathy, nephropathy, and retinopathy (1).

Considerable process bottleneck also persists in the process of insulin and other antidiabetic drugs punctuation even with all the significant strides that have been achieved in the area of pharmacological interventions. Even though subcutaneous injection is efficient in glycemia management, it is also associated with pain, needle phobia and the danger of infection and low patient adherence particularly in pupil age or old age. The old route of administration is through oral intake of insulin which is easier to administer to patients, however with the destruction of enzymes in intestines, and being less permeable across intestinal epithelium, instantaneous bioavailability is irrelevant. All these problems prove the urgent need to find a non-invasive, non-injury, and effective method of delivering insulin to the blood stream which will be capable of producing long-range increases in plasma levels without inducing discomfort in the patient (2). It has been noted that transdermal route is emerging as a viable alternative route of administration to have the following merits: circumvention of hepatic first pass metabolism, permanent plasma drug concentrations, and increased patient adherence (3). However, the skin of a human being is a very hard shield against drug permeation. The stratum corneum is a layer of corneocytes arranged in a network of lipids, an effective macromolecule barrier, i.e. insulin (molecular weight 5800 da) and other hydrophilic peptide (4). In order to cope with such obstacle, more traditional chemical enhancers and physical methods (iontophoresis, microneedles, sonophoresis) were examined, but all of them possess their restrictions in terms of either safety, complexity or costs (5).

In the last several years, ionic liquids (ILs) salts comprising organic cation and organic/inorganic anions that do not solidify below temperatures of 100 o C have been of great interest as potential pharmaceutical excipients, as these have the potential to enhance the solubility, stability and permeability of compounds at the skin. They are tunable and polarity, hydrophilicity, and lipophilicity allow control of pharmacokinetic interactions between drugs and skin with great precision because of their tunable physicochemical properties (6). Another potential which is significantly important is the transdermal delivery of the macromolecular and hydrophilic drugs (e.g. insulin and glucagon-like peptide analogues) by the ILs, which can be applied to fluidize the lipid bi-layers and to hydrate the stratum corneum (7). Also non-ionized natural biocompatible ILs (i.e. choline, amino acids or fatty acids) were also found to be low cytotoxicity and high formulation stability and could be clinically adapted (8).Having these properties, ILs provide a new trend in transdermal therapeutics. Research principles, mechanism, strategies of formulations and therapeutic implications of IL-based transdermal systems is critically examined with special attention on the delivery of antidiabetic drugs. It also examines the current problems, safety concerns, and opportunities of developing transdermal platforms that have the IL ability to replace the regular insulin injections. The overall goal is to design an integrative piece of knowledge on how ILs can revolutionize management of diabetes by enabling patient-centered administration of non-invasive macromolecular therapeutics continuously.

Ionic Liquids to Drug Delivery

This paper seeks to determine the definition and categorisation of Ionic Liquids. Ionic liquids (ILs) consist of salts of giant organic cationic and organic or inorganic anions that exist in the wet state at or less cold weather (under 100 o C). In comparison to the conventional solvents, ILs are described as having a low boiling point, good permeability, and astonishing tunability because of their capacity to tune the structure of their ionic constituents (9). The features make them attractive in pharmaceutical model where biocompatibility and physicochemical adaptability are essential in physicochemical studies. Three generations of ILs are usually distinguished in terms of the sources and the mode of operation. The type of salts of the imidazoles or halides type are referred to as first-generation ILs, the production of which is typically intended primarily in the industry, yet this production is commonly hampered by its toxicity and mal-biodegradability. Biologically compatible moieties (e.g., lactate, acetate, amino acids) are seen to be conjugated to the backbone of Second-generation ILs to enhance solubility as well as reduce toxicity. Bio-ionic liquids (Bio- ILs) indeed are completely formed based on biocompatible ions such as choline, amino acids or natural metabolites that are destined to be utilized in the biomedical set up (10). Recent literature highlights the use of choline-based ILs (e.g., choline geranate, choline oleate) and amino-acida-based ILs (e.g., arginate, glycinate) due to the fact that they are a better option compared to others due to high skin penetration, low cytotoxicity, and biodegradation. This IL mixing and matching enables directed design of formulations (to deal with drug molecules e.g. hydrophilic peptide to hydrophobic small molecule) (11).

There are certain significant physicochemical properties that are pertinent in transdermal delivery

Exceptional versatility of ILs is attributable to modularity of the ionic structure, which determines the capacity to solvate, polarity, viscosity, and the ability to form hydrogen-bonds. The three parameters can be optimized to regulate drug solubility, stability and diffusion across the skin barrier. The ILs are also characterized by a lack of solubility, as they can dissolve polar and non-polar molecules and, as such, address the solubility issues that can easily affect transdermal preparations (12). One such solubilized insulin is choline-based ILs that are reported to maintain the insulin secondary structure and inhibit aggregation or denaturation of insulin on storing (13). Besides that, these liquids possess an ionic nature that enables to associate with drug molecules, and lipids of the skin through electrostatic and hydrogen bonds, which also helps to increase thermodynamic activity of the drug molecule in the skin surface as well as the flux. Even natural moist characteristics of ILs promote the humidity of the skin, and promote diffusion of liquids. Their amphiphilic nature allows them to be intercalated through the lipid bilayers of the stratum corneum resulting in the lipid matrix being temporarily discontinued without inflicting permanent damage (14). All these attributes make ILs multi-purpose excipients, which would be utilized to act as both solvents, permeation enhancers, stabilizers as well as co-formulants in termed-dermal future systems.

Regulatory Considerations safety and biocompatibility

The potency of ILs in drug delivery system is well recognized and very effective but their biocompatibility and safety parameters remain critical for determination of clinical translation. In early time some imidazolium- or pyridinium-based ILs showed cytotoxicity and irritation due to presence of strong lipophilic cations and halide anions (15). To attenuate these results, this research focuses on “green” ILs synthesized from endogenous ions or biodegradable precursors, like choline, amino acids, organic acids, or carbohydrates (16). The presence of bio-ILs hasillustrated appropriate compatibility with keratinocytes and fibroblasts and less haemolytic activity, and negligible irritation in ex-vivo skin models. Pharmaceutical applications of ionic liquid is still emerging and required regulatory guidelines There are various organizations or authorities like U.S. FDA and EMA still does not define and standard procedure or flow chart for ionic liquid formulations. Now days in the transdermal and topical formulation the presence of ionic liquid are increasing However, the increasing has prompted the establishment of safety evaluation protocols emphasizing acute and chronic dermal toxicity, sensitization, and biodegradation studies. To optimized safety profile and reduced environmental effect advances in computer aided toxicology and digital simulation modelling are being used to create ionic liquid.[17]

Structural Design Strategies and Tunability

One characteristic of IL technology is that it is structurally tunable (i.e., cation anion combinations can be adjusted to desired physicochemical behaviour precisely). Viscosity and hydrophobicity are influenced by the cation, which can be imidazolium, pyridinium, ammonium, or phosphonium, whereas the anion, which determines the ability of hydrogen-bonds and biocompatibility can be acetate, lactate, or geranate (18). To use ILs in the transdermal delivery method, ILs with medium hydrophilicity and low viscosity are desired because they can diffuse through stratum corneum with ease and are non-toxic and can interact with lipid membranes. More so, there is the advent of task-specific ILs (TSILs) where functional groups (e.g., hydroxyl, carboxyl or amide) are covalently modified to the ions to provide extra functionality-e.g. antioxidant, anti-inflammatory activity. This method does not only increase the therapeutic effectiveness but also permits bioactive loading (19). The optimal development of ILs based on the rational design with the assistance of computational simulations, QSAR modelling, and molecular docking would expedite the discovery of ILs that may be considered with peptide-based drugs such as insulin.[18]

ILs-Mediated Transdermal drug Delivery system

The skin offers a good physiological barrier to most environmental risks and at the same time hinders percutaneous absorption of therapeutic agents, especially the macromolecules like insulin. The corneosomes in a lipid matrix that make up stratum corneum (SC) form the major barrier to diffusion. Ionic liquids (ILs) have become effective agents of permeation enhancement with the ability to transiently alter SC structure and support drug partition and diffusion

without adversely affecting skin integrity. Their action occurs in a combination of physicochemical and biochemical pathways that enhance the flux of drugs through the skin as a whole.[19-20]

Modulation of skin-barrier and Lipid Fluidization

The ILs are able to respond to the ordered lipid bi-layers of the SC by being electrostatically, hydrogen-bonded and van der Waals interacting. These interactions destabilize the lipid packing, and it becomes more fluid, with micro-channels that temporarily form in the lipid that can transport drugs (20). Small-angle X-ray analysis and ATR-FTIR analysis have shown that choline-based ILs eliminate the conformational order of fatty acids and ceramides and, therefore, make permeable (21). Notably, these effects are reversible, as when the formulation is bound away, the lipid matrix begins to re-form its native arrangement slowly retaining the protective capability of the skin. This is the reversible fluidizing of lipids that makes ILs stand out among other harsher chemical fixatives like DMSO or azones which can lead to irreversible lipid extraction (22).Electrostatic and Molecular Interactions with Drug Molecules: The molecular and atomic structure of the drug molecules is modified by their binding to cyanobacteria cells.<|human|>Electrostatic and Molecular Interactions with Drug Molecules: Interaction of drug molecules or its cyanobacteria cells changes the molecular and atomic structure of these cells.

The ionic property of ILs facilitates their ionic pair formation or dynamic complex with charged or polar drugs. In the case of peptides like insulin, ILs are able to cause the electrostatic repulsion between the drug and the skin lipids to decrease, which in turn raises the effective partition coefficient across the SC (23). It has been shown using computational simulations and through molecular docking experiments that IL anions (e.g., acetate, lactate, geranate) interacts with G-plus and C-terminal amino-acid residues of insulin via hydrogen bonding to stabilize its secondary structure during permeation (24). Moreover, the aggregation is inhibited by cationionic and hydrogen-bond interactions that leave monomeric insulin suitable in values of diffusion. These are synergistic effects of these molecular interactions to enhance drug stability and transdermal flux.

Improvement of drug solubility and thermodynamic activity can be made

Most anti-diabetic drugs are insoluble in water or lipid, and this limits the gradient of their diffusion through the skin. The ILs are two-solvent systems that allow the solubility of hydrophilic and hydrophobic drugs. Such wide solvation capacity enhances the thermodynamic activity of the drug in formulation hence amplifying its propulsive power to penetrate (25). Moreover, the micro-polar spaces in ILs obtain uniform distribution of drugs, preventing their formation of precipitate and providing uniform dosage across the patch matrix. Indicatively, cholinegeranate ILs have shown differences in insulin solubility tendency of up to 25-fold in relation to other aqueous buffers (26).

Hydrating and Occluding Effects

The ILs tend to be hygroscopic and humectant molecules and capable of trapping and retaining moisture in the SC. More hydration also softens the keratinocytes and swells the intercellular lipid layers, which increases the diffusion routes of hydrophilic drugs (27). Also IL-based formulations often develop a low level of occlusive microenvironment that inhibits trans epidermal water loss, which in turn maintains hydration and increases drug flux. Such effects of hydration would particularly apply to diabetic patients whose skin is usually dry and micro-cracked making them permeable and healing impaired.

Multifunctional Delivery Systems Synergistic Action

In addition to personal impacts, ILs are synergistically enhanced by incorporating into products, like ethosomes, microneedles, and ionic-liquid-in-oil microemulsions. In the IL-ethosomes, both vesicular and SC lipids become fluidized in the il, and hence this enhances deep skin absorption, preserving insulin stability as well (28). IL-microneedle arrays are based on using mechanical micro-perforation of an IL-mediated solubilization to achieve rapid but sustained release (29).

• IL-iontophoresis systems It makes use of the natural conductivity of ILs to further enhance electromotive transport of charged species (30).

These kinds of system are typical examples on the diverse role of ILs which are not only boosters but are dynamic functional excipients to balance chemical-physical and electrical processes to produce the best results in transdermal drug delivery.

Molecular-Level Understandings and Computations

New scientific achievements have been made in molecular-dynamics (MD) simulations affirming some atomic-based interfaces between ILs, skin lipids and peptides. Such simulations support the beliefs of cationic head-groups of ILs in the lipid head-region, and, as anions orient in polar domains, the result in bilayer expansion and free volume increase (31). Experimental evidence and free-energy calculations The effect of IL-mediated permeation is that it reduces the activation energy required to translocate drugs by 20-40 per cent, based on ion pair structure (32). The combination of the empirical data with computational modelling will facilitate the rational IL design optimization in terms of the particular molecular weight, polarity and target flux rates.[32]

Recipes of Ionic Liquid-Based Transdermal

Introduction of ionic liquids (ILs) into transdermal drug delivery systems (TDDS) has transformed the design of formulations of macromolecular therapeutics, especially insulin. Due to the dual effect of acting as solubilizers and permeation enhancers, ILs may be included into different delivery systems such as vesicular carriers, microemulsions, polymeric patches, and microneedle arrays. The objectives of these formulations have been to surpass the shortcomings of the stratum corneum barrier, enhance a sustained-release, and maintain a constant plasma insulin level to enhance the therapeutic and adherence rates of a patient. The IL-Integrated ethosomes are electroporation efficiencies of proteins into cell membranes, whereas trans-ethosomes refer to the interactions between electroporation and transfection (on-the-fly genetic Engineering).<|human|>The IL-Integrated ethosomes and trans-ethosomes The IL-Integrated efficiencies of electroporation into cell membranes are known as ethosomes, and trans-ethosomes are defined as the interaction of electroporation and transfection (on-the-fly genetic Engineering).

Ethosomes high-ethanol phospholipid-based nanovesicles that are meant to increase transdermal penetration through lipid fluidization. Ethosomes are synergistically augmented when used with ILs in the measurement of permeability and stability. Vesicle deformability is enhanced by far more through the addition of biocompatible ILs, e.g., choline geranate (CAGE) or choline oleate, which enhances the solubilization of insulin and other hydrophilic peptides (33). Recent reports have established that IL-mediated ethosomal systems are capable of insulin delivery through unbroken skin, bulk prolonged levels of near normal blood glucose in diabetic model (34). Furthermore, modified vesicular systems including the trans-ethosomes (TETs), which combine both ILs and edge activators, e.g. Tween 80 exhibit better elasticity enabling them to penetrate deeper into skin. The systems can not only increase insulin bioavailability but also help prevent enzymatic degradation, which preserves its structure maintained during delivery (35). The size of the vesicle, value of zeta potential, and entrapment efficiency are changes by the physicochemical properties of ILs such as viscosity, polarity, and ion-pairing capacity. This step leads to the optimization effects of these parameters, which lead to drug formulations that are less prone to instability and regulated release profiles and can be used in long-term insulin therapy.

IL-in-Oil Microemulsions

Another promising carrier to transdermal delivery of insulin is ionic-liquid-in-oil (IL/O) microemulsions. These thermodynamically stable isotropic systems make use of ILs as either internal or co-solvent phase to improve drug solubilization and transdermal diffusion. ILs have an amphiphilic property and this enables easier interfacial localization, reduces surface tension and provides easier emulsification without the need to use surfactants in high concentrations (36). It has also been shown that IL-based microemulsions can be used to sustain and controlled discharge of insulin 24-48 hours without a significant burst out of insulin. Indicatively, ILs like choline propionate and imidazolium lactate are good examples that have been proven to increase the insulin flux with keeping the skin compatible (37). Radioactive ILs show better biocompatibility, less erythema, and retrieve stability of physiological

conditions in comparison with conventional chemical enhancers (38). In addition, the lax nature of IL microemulsions allows the co-encapsulation of other excipients, e.g., antioxidants or humectants, which counter of the oxidative breakdown and promote skin hydration. The property is especially important in diabetic skin that tends to be dry and therefore has defective barrier ability.

Microneedle Arrays (MNA) Functionalising with Ionic Liquids.

Microarray of microneedles (MNAs) have been of interest as minimally invasive systems with the ability to produce microchannels in the dermis layer of the skin by passing through the stratum corneum and causing minimal pain and tissue injury. The combination of ILs into microneedles offers two benefits: (1) it increases the solubility of insulin and (2) it allows the insulin to be released in a slow manner due to the interaction of ILs with polymer matrices (39). More recent trends in the IL-loaded dissolving microneedles affixed to biocompatible polymers (e.g., hyaluronic acid, PVA, PVP) have shown that efficient insulin delivery can be achieved with a rapid onset and long-lasting effect on hypoglycaemia. The ILs fix the peptide into the matrix, stop aggregation during the fabrication process and promote diffusion, after being incorporated into the skin (40). In addition to this, hybrid microneedle systems, which include ILs and stimuli-responsive polymers provide an opportunity to have smart insulin delivery in response to temperature or glucose levels in line with the objectives of closed-loop diabetes therapy.[40]

Polymeric Patches and Films

To incorporate both the controlled release and the benefit of mechanical flexibility and convenience to the patients, polymeric transdermal patches have been developed that contain ILs. ILs are functional permeation enhancers and plasticizers - planes that enhance the elasticity of polymers. It has been stated in researches that patches made with IL-insulin complexes prepared with the use of biocompatible matrices i.e. hydroxypropyl methylcellulose (HPMC) or ethyl cellulose, release insulin steadily more than 24 hours and provide stable glycaemic regulation in diabetic models (41). The decision of IL level is decisive: low content of IL can lead to poor permeation, but at the same time, high content of IL can influence the viscosity, or cause slight irritability. A balance between these parameters guarantees an excellent formulation with good release kinetics, skin compatibility and patient safety.

Synergies and Hybrid Recipes

The versatile nature of ILs enables them to be used together with other complex transdermal technologies to form hybrid systems with enhanced performance. Examples include:

- IL-carrying ethosomes into microneedle arrays with high-onset and long-term release (42).
- Adhesive patches based on IL-microemulsion which combine increased soluble properties and longer skin adhesive properties.
- Stimuli-sensitive IL systems, which can regulate the release of insulin when reacting to biological signals e.g. glucose level or pH (43).

Indeed, such composite systems meet the paradigm shift in the directions of the personalized, non-invasive management of diabetes, offering flexibility in the dose delivery, patch wear-time, and comfort to patients.

IL-Based Transdermal System Optimization Parameters

The choice of design of the formulation is dictated by several parameters such as IL type, concentration, size of the particle, pH, viscosity and compatibility with skin lipids. Some of the important optimization factors are:

- Precise ionic structure optimization (i. e. cation-anion pairing) to balance between hydrophobicity and hydrophilicity.
- Encapsulation efficiency and drug-loading capacity, which are crucial in the process of delivering macromolecules with a high dose.
- Stability in terms of temperature and chemical performance, which guarantees long shelf life, and so no degradation of peptide.
- Ex-vivo permeation and in-vivo pharmacodynamic analysis, which ensures it was translated in the laboratory to maintain physiological condition (44).

New tendencies dwell upon the utilization of the green ILs produced using renewable resources to facilitate the sustainable and regulation-friendly design.

Ionic Liquid based transdermal systems have clinical implication and benefits

The use of ionic liquids (ILs) in transdermal delivery systems is one of the significant breakthroughs in non-invasive treatment of diabetes. These systems have important clinical advantages to traditional insulin administration modalities in that, they improve pharmacokinetic profiles, decrease the patient burden and increase adherence. The clinical implications go beyond convenience including enhanced glycaemic control, reduced systemic variability and the quality of life among diabetic patients. The major clinical benefit of IL-based transdermal systems is the non-invasive delivery system. The conventional subcutaneous injection of insulin is effective but is linked to pain, local tissue damage, and needle phobia which are highly detrimental to patient adherence particularly in paediatric geriatric and needle-averse populations (45). By comparison, IL-enhanced patches or microneedle systems do not require injections, but rather painless delivery to the body through intact skin. The IL-mediated ethosomal and microneedle systems have been investigated and proved to be effective in percutaneous insulin in absence of erythema or inflammation (46). Self-administration of a patch instead of injections develops patient independence and long-term effects, which are the two important parameters of the successful diabetes management. Such non-invasive systems also minimize Sharps-related injuries, and contamination risks with using needles reused in case of using a sharp.

Rollover and Regulated Insulin Discharge

The other significant clinical benefit is the insulin sustained and regulated release which is attained by IL-based formulations. In contrast to subcutaneous injections which cause sharp rises in plasma insulin concentration and exponential decreases, IL-based systems stabilize plasma insulin level in the long-term (47). This constant administration decreases the glycemic instability, decreases the risk of hypoglycaemia and resembles the natural physiologic secretion pattern of insulin. In fact, IL-in-oil microemulsion delivery methods have been reported to release insulin up to 48 hours and keep euglycemic in animals (48). Equally, ethosomal formulations through IL-mediated delivery portrayed a regulated delivery within 24 hours, which guaranteed the regulation of glucose continuously (49). These results highlight the clinical potential of IL-based delivery, which could cause a decrease in the frequency of injections, simplify the dosage schedule, and enhance contentment with patients.

Enhanced Pharmacokinetic and Pharmacodynamic Performance

The ILs have the ability to regulate the pharmacokinetics (PK) and pharmacodynamics (PD) of insulin by enhancing penetration and increasing the bioavailability of insulin in the body and increasing its half-life. The transdermal flux is also more predictable and higher because ILs disrupt lipid bi-layers and increase the local hydration (50). Bioavailability of patches or micro needles by IL or subcutaneous injection can typically be close to each other; however, combining lower inter patient variability. In addition, ILs stabilize peptide conformation, thus preventing aggregation or degradation, maintaining homogenous pharmacological activity (51). Regulated delivery reduces the oscillations in peaking and troughing, which is a factor in decreased oxidative stress and improved long-term metabolic regulation, which is essential in preventing diabetic complications, including neuropathy and retinopathy (52).

Improved Patients Adherence and best lethargy of life

Compliance is another significant problem in chronic illnesses like diabetes, in which the management process must be lifelong. This problem is directly met by the IL-based transdermal systems that make the therapy easier. Physical and psychological burden of using several injections every day is reduced by the ease of applying patches once every day or alternating every day (53). Psychosocially, discreet and needle-free administration enhances confidence in the patient, lowers the level of stigma and encourages active disease control. Better compliance has been translated to better glycaemic control, less hospitalization, and lowered long-term healthcare expenditures. These advantages are

in line with the aim by the World Health Organization (WHO) to optimize adherence by ensuring that delivery systems are user friendly.

decreased Systemic Side Effects and Local Irritation

Non-specific lipid extraction usually results in the irritation, erythema, or the disruption of the barrier with traditional enhancers. Conversely, biocompatible ILs, particularly the choline- or amino acid-derived ones, have low cytotoxicity and reversible lipid remodelling (54). These ILs preserve skin integrity despite repeated usage and this is crucial to chronic insulin treatment. Also, IL-based systems administer insulin into systemic circulation bypassing hepatic first-pass metabolism, decreasing systemic changes, and minimizing adverse events such as hypoglycaemia. These two factors concur in promotion of the overall safety profile of the therapy due to the localized effect and decreased variability (55).

Interactions with Individualized and Combination Therapy

ILs provide molecular tunability which can be used to provide personalized medicine. Their ionic structure may be modified to suit the polarity, molecular weight and charge of particular antidiabetic agents. Besides, IL-based TDDS could be designed to co-deliver insulin with other therapeutics, such as glucagon-like peptide-1 (GLP-1) analogues or DPP-4 inhibitors to produce synergistic glycaemic control (56). More sophisticated IL-based patches are also under development as smart and stimuli-responsive drug delivery, in which insulin is released in response to both real-time glucose changes or temperature changes (57). These bio responsive systems will have the potential to mimic the pattern of physiological secretion of insulin, which will result in closed-loop delivery of transdermal insulin.

Economic and Compliance Considerations

Regarding healthcare economics, IL-based TDDS have the potential of saving money by minimizing the number of hospital visits, complications, and treatment-related consumables (e.g., syringes, needles). The enhanced patient compliance is directly related with the improved glycaemic outcome and low disease burden in the long run. The implementation of IL-based systems might require more formulation expenses initially, but scalability and patient value offset these expenses, and the costs are thus cost-effective to implement on a large-scale clinical basis.

Difficulties and Future Projections

Although using ionic liquid (IL)-based transdermal systems has impressive potential in changing the paradigm of antidiabetic treatment, a successful clinical implementation of this technology faces a number of scientific, technological, and regulatory hurdles that need to be overcome. Even with attractive preclinical evidence, there have been challenges on safety, scaling, reproducibility, and patient specific variability, which act as deterrents towards large scale implementation. Further studies in this area should aim at designing better forms of formulations, long term bio compatibility, and regulatory policies to promote IL-based innovations with regard to formulating pharmaceutical delivery.

Safety and Biocompatibility Issue

The greatest problem in the development of IL-based transdermal systems is the dermal and cytocompatibility assurance. Certain first-generation ILs - especially those that harborimidazolium or pyridinium cations and halide anions - trigger skin irritation, cytotoxicity or lipid extraction at elevated concentrations (Jain et al., 2024). These effects are attributed to their high lipophilicity, as well as charge density, which interferes not only with the stratum corneum (SC) lipids but also with viable epidermal cells. Innovations in the recent past have resulted in production of biocompatible ILs that are made using natural sources like choline, amino acids or fatty acids which demonstrate enhanced tolerability and reversible lipid modulation. However, on long-term toxicity information, particularly in situations concerning chronic application as in management of diabetes, is deficient. In-vitro experiments which include cytotoxicity, irritation, sensitization, and in-vivo dermal tolerance need to be performed comprehensively to establish their safety upon usual human use. In addition, ILs can enter the dermis, so the option of systemic

absorption and bioaccumulation needs to be considered. Future research needs to incorporate the pharmacokinetic and toxicokinetic evaluations to determine the safety limits, and be used to make clinical dosage suggestions.

Regulatory and Standardization Problems

Regulatory environment of the IL-containing pharmaceuticals is not much defined yet. Although FDA, EMA and others consider ILs as novel excipients, they are very demanding on extensive characterization and safety testing before these are approved. At present, there is no uniform application of guidelines to toxicological testing, nomenclature, and stability testing, which is an issue of concern to developers wishing to have the specifications approved by the officials. To create a bridge between these two, there is a need to have joint efforts of educational institutions, industry and regulatory authorities in establishing standardized Good Manufacturing Practice (GMP) protocols of IL synthesis and purification. By defining unified regulatory-focused routes such as those of polymers or nanocarriers, it will be easier to incorporate ILs into the accepted repository of pharmaceutical excipients and expedite the corporate adoption of clinical translation.

Scalability and Limitation of the manufacture

Another major challenge is the large-scale generation of IL-based transdermal formulations. The ILs are often hygroscopic, viscous, and sensitive to moisture or temperature making it tough to handle and reproducible. To provide therapeutic performance reproducibility, batch to batch consistency especially in IL purity and stoichiometry is crucial. Also, mass production of microneedles or patches of ethosomal or microemulsions containing IL requires special equipment and expensive procedures. The emergence of green solvent-free synthetic pathways, as well as automated mixing technology, will be important in scaling to commercial level. The combination of the principles of continuous manufacturing and quality-by-design (QbD) is capable of standardizing IL production with minimal harm to the environment and cost. A stabilizing effect on sensitive biomolecules such as insulin can be achieved by forming network-like hydrogen bonds which can eliminate denaturation of the cation exchange; but long-term stability of storage is an issue. Humidity, light, temperature changes, and others can change the IL structure and affect the formulation integrity. The design of ILs with increased oxidative and hydrolytic stability, and the coming up with protective multilayer patch formulas, will increase the shelf life, and the potency of drugs will be maintained consistently during storage and transportation.

Pharmacokinetic Changeability and Individual Patient Considerations

When skin properties vary between interindividuals, e.g., S. hydrata, lipid composition, pH, microcirculation, etc. different solutions are variable in their absorption of ILs. This variation can be also enhanced among those patients with diabetes, as such patients can have distorted skin microstructure and reduced barrier functions. One-to-one optimization of IL-based formulations reducing IL concentration, drug loading and matrix design is thus essential to achieve constant therapeutic effects. The future of computer-aided approaches can be seen in emerging physiologically based and machine learning-based computational models that can predict the person-specific response, and thus allow the future of customization of both dosage and the formulation to be performed in a clinical practice.

Environmental and Sustainability Conflocations

In spite of being non volatile, there are some ILs that have environmental risks in terms of lack of biodegradability and aquatic toxicity. Making eco-friendly or green ILs with renewable biomaterials as a choline chloride, natural fatty acids, and amino acids are a key step to a sustainable pharmaceutical development. The principles of green chemistry should be followed in future formulations, keeping to the focus on renewable feedstocks, with recyclability and reduction of the waste generated. Switching to biodegradable ILs is in line with the global regulations requirements and will not pose any environmental hazard during the manufacturing process, consumption, and disposal.

Future Research Directions

Future development of IL-based transdermal systems will probably be based on intelligent, feedback, and multimodal delivery systems involving the incorporation of ILs with biosensors, nanocarriers, and polymeric matrices. Some key directions include:

- The adoption of and the stimulus-response IL systems, which adjust the release of insulin in real-time according to the glucose level, will allow the closed-loop administration of transdermal insulin.
- Hybrid microneedle systems that combine ILs and nanogels, liposomes, or microemulsions in order to obtain high onset and long-term therapeutic effect.
- Artificial intelligence ILs computational molecular engineering prediction of skin interaction and drug compatibility through artificial intelligence and molecular dynamics.
- Clinical translation by the use of properly designed phase I/II clinical trials, which prove safety, efficacy, and acceptability by patients.
- Existing regulatory frameworks development to accommodate ILs as approved excipients in pharmacopeia and allow commercialization on a global basis.
- The future of the field researches based on inter-disciplinary interactions between chemists, pharmaceutical scientists, bioengineers, and clinicians will be crucial to unleash the complete therapeutic power of ILs in diabetes treatment.

SUMMARY

To conclude, IL-based transdermal systems to deliver drugs can provide the potential of transformation in insulin administration that is not invasive; however, the transition to clinical reality is associated with the challenges of safety, stability, scaling, and control. The future of these therapeutic systems will be evaluated by continuous innovation in the IL chemistry, green synthesis and intelligent formulation design that is immunized by strong clinical validation. Inclusivity of material science, bioengineering and digital modelling has the answer to the achievement of personalised, sustainable, and patient-centric transdermal therapies to manage diabetes.

CONCLUSION

The last 10 years have seen a revolution in pharmaceutical innovation with ionic liquids (ILs) becoming highly effective instruments to breaking through established barriers to transdermal drug delivery. Their combination of unprecedented adjustability in physicochemical characteristics, multifunctionality and biocompatibility make them next-generation excipients that could revolutionize the delivery of macromolecules like insulin. The considered evidence highlights that the ILs are not only solubilizers and permeation enhancers, but also stabilizers and co-formulators as well, which guarantees structural stability and continuous release of the therapeutic agent. ILs are useful in transporting hydrophilic and high-molecular-weight biomolecules by facilitating the permeation of high-molecular-weight proteins across the stratum corneum that was previously believed to be an impossibility by utilizing the skin because of the tight correlation between the lipid architecture and the formation of transient permeation channels. Their having been incorporated successfully in sophisticated delivery structures, including ethosomes, microemulsions, polymeric patches, and microneedle arrays has shown strong preclinical outcomes, with a long-lasting glycemic control with minimal irritation or toxicity.

As clinical delivery methods, IL-based transdermal systems have a tremendous potential to substitute or complement subcutaneous injections by providing a painless, patient-compliant and long-term alternative to drug delivery that would lead to improved adherence and quality of life. In addition to insulin, these systems have the potential to be changed to co-deliver a range of antidiabetic agents, therefore opening the way to personalized and combination therapies. Caution in IL chemistry is enabling the development of specific dosages to match the patient, it becomes variably adjustable in response to change in skin physiology and pathophysiology. However, there are still a number of obstacles to complete clinical shift. The long-term dermal safety, regulatory acceptability, scalability during its synthesis, and the environmental sustainability are a major concern of current research. Academic, industry, and

regulatory organizations should collaborate to set up standardized testing guidelines, safety standards, and manufacturing habits of IL based pharmaceutical excipients. It is expected that the idea of II technology will converge with smart, stimuli-responsive systems that emit insulin upon the occurrence of real-time glucose variations, closer to the bona fide closed-loop transdermal insulin treatment, in the future. The use of molecular design, computational models and integration of biosensors would further enable a faster development of IL-mediated systems out of the laboratory and into clinical care. Summing up, transdermal systems using ionic liquids are the game-changing product in the field of antidiabetic treatment. These systems can transform the insulin and other biomolecule delivery by combining chemical ingenuity and biomedical engineering. Further interdisciplinary studies and investigations based on the principles of biocompatibility, sustainability and patient friendly design will dictate when this promising technology will be able to swiftly move out of the laboratory stage of experimental innovation to an actual mainstream therapeutic reality in diabetes management in the global setting.

ABSTRACT

The concept of edge coloring of graphs has numerous practical applications in diverse domains, such as computer science, operations research, and telecommunications. Some notable applications include scheduling problems, Telecommunication Networks, Register Allocation in Compilers, VLSI Design (Very-Large-Scale Integration), Traffic Flow Management, Parallel Computing and Chemical Reaction Networks. The edge-chromatic number, also known as the chromatic index, of a graph $\mathcal{G}$ is the smallest number of colors required to properly color the edges of $\mathcal{G}$ such that no two adjacent edges share the same color. Vizing[1] established that for any simple graph $\mathcal{G}$, the edge-chromatic number is either $\Delta(\mathcal{G})$ or $\Delta(\mathcal{G})$ + 1.Graphs are classified based on their edge-chromatic number into two categories: Class-One graphs, where the edge-chromatic number equals $\Delta(\mathcal{G})$, and Class-Two graphs, where the edge-chromatic number equals $\Delta(\mathcal{G})$ + 1.Although Vizing's theorem provides significant insight into edge chromatic numbers, determining whether a graph belongs to Class-One (or) Class-Two remains unresolved. Vizing introduced the concept of critical graphs to tackle this challenge. A connected Class-Two graph **in which** the removal of any edge reduces its edge-chromatic number is called edge-chromatic critical. A critical graph is referred to as Δ-critical if its maximum degree is Δ. Vizing [2] conjectured that "If$\mathcal{G}$ is a Δ – critical simple graph within vertices, medges and $\Delta \geq 3$, then $m \geq \frac{1}{2}\left[(\Delta-1)n+3\right]$" . Limin Zhang et al.[3] proved that $n_\Delta \geq 2\sum_{k=2}^{\Delta-1}\frac{n_k}{k-1}+\frac{1}{2}n_3$ for any critical graph with $\Delta \geq 4$. This paper studies the size and n_Δ of three categories of edge-chromatic critical graphs with maximum degree 7. The bounds obtained on size and n_Δ in this paper are improved bounds than the existing known bounds.

Keywords: Class-One, Class-Two graphs, edge chromatic critical graphs.
AMS subject classification code: 05C15

INTRODUCTION

The concept of edge chromatic critical graphs emerges from the broader study of graph coloring in mathematics, a field with deep historical roots and significant applications in areas like scheduling, network theory, and optimization. The mathematician VadimVizing made a monumental contribution to edge coloring theory with his Vizing's Theorem (1964). The term "edge chromatic critical graph" and the investigation of such graphs became more prominent as mathematicians explored the intricacies of Class-Two graphs. While Vizing's Theorem gave the two possibilities of the chromatic index, the study of critical graphs provided a fascinating case study of graphs that exhibited "maximum difficulty" in coloring. These graphs have the distinctive property that their chromatic index is $\Delta(\mathcal{G})+1$, and they are critically dependent on every edge for maintaining this property. Research into these graphs has highlighted their unique structural properties and their utility in solving real-world problems. The study on "edge-chromatic critical graphs" blossomed as a way to explore the boundaries of applications of graph theory in problems of optimization and scheduling. While edge chromatic critical graphs were first studied primarily in the context of theoretical graph theory, their applications began to surface in fields such as telecommunications, scheduling, and transportation, where edge coloring plays a crucial role in resource allocation without conflicts. The mathematical beauty and practical utility of these graphs sparked a growing interest in their study.

In the years following the introduction of edge chromatic critical graphs, mathematicians continued to explore their properties, searching for new classifications, algorithms, and methods to efficiently solve coloring problems. They also became a focal point for the development of algorithmic graph theory, where the aim is to develop efficient methods for determining the chromatic index and finding critical graphs. The history of edge chromatic critical graphs is closely intertwined with the broader history of graph coloring theory. From Euler's early work on graphs to Vizing's groundbreaking theorem, the field has evolved to explore the delicate balance between structure and constraint in edge coloring. Today, edge chromatic critical graphs represent not only a deep theoretical area of study but also a practical tool in fields like network design, resource allocation, and optimization. Their history is a testament to the ever-growing connection between mathematical theory and real-world applications. Edge chromatic critical graphs, though a relatively specialized topic in graph theory, have garnered significant attention due to their intriguing structural properties and applications in various optimization problems. The initial studies on edge chromatic critical graphs focused on understanding their structural properties and identifying specific examples. Early works in the 1960s and 1970s identified well-known graphs, such as certain complete bipartite graphs $K_{n,n+1,}$ as edge chromatic critical graphs. These graphs were analyzed to demonstrate how small changes in the graph structure (such as edge removal) directly influence the chromatic index.

In the decades following the initial discovery of edge chromatic critical graphs, mathematicians sought to classify and characterize these graphs. While the foundational work on these graphs dates back several decades, ongoing research continues to uncover new properties and applications. Their study not only deepens our understanding of graph coloring but also provides valuable insights into resource allocation, network design, and scheduling problems in real-world scenarios. As the field of graph theory continues to evolve, edge chromatic critical graphs will likely remain a key area of theoretical exploration and also practical application.

Notations

The graphs discussed in this article are simple graphs consisting of n vertices and m edges.The degree of the vertex ν is represented by $d(\nu)$. $\Delta = \max\{ d(\nu) / \nu \in V(\mathcal{G}) \}$. ν is termed as a "major vertex" when $d(\nu)= \Delta$. ν is termed as a "minor vertex" when $d(\nu) < \Delta$. $N(\nu)$ denotes the collection of all neighbours of the vertex ν &$N(u,\nu) = N(u) \bigcup N(\nu)$. $[\mathbb{V}_1, \mathbb{V}_2]$ represents the collection of all edges with one of the endpoints in $\mathbb{V}_1$ and the other in $\mathbb{V}_2$. The subgraph of $\mathcal{G}$ induced by subset $\mathbb{S}\subseteq V(\mathcal{G})$is represented by $[\mathbb{S}]$ and $|[\mathbb{S}]|$ represents the number of edges in $[\mathbb{S}]$. $|[\mathbb{V}_1, \mathbb{V}_2]|$ represents the cardinality of $[\mathbb{V}_1, \mathbb{V}_2]$.$\mathbb{M}$is the collection of all major vertices in $\mathcal{G}$.$\mathcal{N}_1$ represents the collection of all vertices whose degree is i in $\mathcal{G}$. A vertex with degree j is referred as j_vertex and n_j represents the count of$j$_vertices in $\mathcal{G}$. These

notations establish a framework for examining graph properties, with a particular focus on vertex degrees, major and minor vertices, neighbourhoods, edge sets, and vertex-induced subsets. They support the analysis and discussion of various aspects of graph structures and properties throughout the paper.

Known Results

Result 3.1: Vizing's Adjacency Lemma (VAL) [4]: In a Δ–critical graph G,if vw is an edge and d(v)=k, then w *is* adjacent with at least Δ - k+1 other vertices of degree Δ. In particular, G has at least Δ - δ +2 vertices of degree Δ.
The following Lemma describes the structure of Δ- critical graphs with edges whose sum of degrees of end vertices equals Δ+ 2.

Result 3.2 (Zhang [5]): Let G be a Δ- critical graph, xy ∈ E(G) and d(x)+d(y)=Δ+2.
Then the followinghold:(i)everyvertexofN(x,y)-{x,y}isamajorvertex(ii)everyvertexof N(N(x,y)) -{x,y} is at least ofdegreeΔ-1(iii) Ifd(x), d(y) <Δ, then every vertex of N(N(x,y)) - {x, y} is a major vertex.

Result 3.3[6]: The average degree of edge chromatic critical graphs with maximum degree seven is at least 6.

Main Theorems

$\mathbb{M}_2$,$\mathbb{M}_3$,$\mathbb{M}_4$,$\mathbb{M}_5$,$\mathbb{M}_6$, $\mathbb{M}_{34}$,$\mathbb{M}_{35}$,$\mathbb{M}_{36}$,$\mathbb{M}_{45}$,$\mathbb{M}_{46}$, $\mathbb{M}_{56}$, $\mathbb{M}_{345}$, $\mathbb{M}_{346}$, $\mathbb{M}_{356}$, $\mathbb{M}_{456}$, $\mathbb{M}_{3456}$ represent the collections of all vertices in $\mathbb{M}$that are adjacent with minor vertices characterized as follows: only2_vertices,only 3_vertices,only 4_vertices,only 5_vertices, only 6_vertices, only 3 and 4_vertices, only 3 and 5_vertices, only 3 and 6_vertices, only 4 and 5_vertices, only 4 and 6_vertices,only 5 and 6_vertices, only 3,4 and 5_vertices, only 3,4, and 6_vertices, only 3,5 and 6_vertices, only 4,5 and 6_vertices and 3,4,5 and 6_vertices respectively. In this article, we obtain new bounds on m and n_Δ which are improved bounds than the known bounds. By VAL, a major vertex cannot be adjacent with 3,4,5 and 6-vertices and hence$\mathbb{M}_{3456} = \phi$.

The papers[7,8,9] give new insights and new bounds on the size and n_Δ of certain families of graphs which are edge-chromatic critical graphs with Δ equals 5, 6 and 7. As a continuation, this article discusses the size and n_Δ of three different families of graphs. The first family is the set of all 7-critical graphs in which (i) every vertex in $\mathbb{M}$ has a vertex in $\mathcal{N}_4$and a vertex in $\mathcal{N}_5$ as its neighbours and (ii) every vertex in $\mathcal{N}_4$has a vertex in $\mathcal{N}_5$ as its neighbour and vice versa. The second family is the set of all 7-critical graphs in which (i)every vertex in $\mathcal{N}_6$ has a vertex in $\mathcal{N}_3$ as its neighbour (ii) every vertex in $\mathcal{N}_5$ has a vertex in $\mathcal{N}_4$ as its neighbour and (iii) for every major vertex v , $\mathcal{N}(v) \bigcap \mathcal{N}_i \bigcap \mathcal{N}_j = \phi$ for all $i \neq j$ and the third family is the set of all 7-critical graphs in which (i)every vertex in $\mathcal{N}_6$ has a vertex in $\mathcal{N}_3$as its neighbour (ii) every vertex in $\mathcal{N}_5$has a vertex in $\mathcal{N}_4$ as its neighbour and (iii)every vertex in $\mathbb{M}$ has at most one minor vertex as its neighbour. In all these three families, improved bounds on the size and n_Δ are obtained.

Theorem 4.1: Ifan edge-chromatic 7-critical graph G satisfies the conditions that (i) every vertex in $\mathbb{M}$ has a vertex in $\mathcal{N}_4$and a vertex in $\mathcal{N}_5$as its neighbours and (ii) every vertex in $\mathcal{N}_4$ has a vertex in $\mathcal{N}_5$as its neighbourand vice versa, then $\delta = 4$, $n_7 = \frac{3}{2}n_4 + 2n_5 = \frac{7}{2}n_4 = \frac{7}{2}n_5$ and $m = 3n + \frac{1}{4}n_4 = 3n + \frac{1}{4}n_5$.

Proof: By VAL, any vertex in $\mathbb{M}$ which has a 2_vertex as its neighbour cannot have any other minor neighbours. Hence by (i),$\mathcal{N}_2 = \phi$. By (ii) and VAL, each 4_vertex has exactly one 5_vertex as its neighbour and vice versa. Thus $n_4 = n_5$. Suppose a major vertex ν has a vertex in $\mathcal{N}_3$ (say u) as its neighbour. By VAL, the vertex v has at least 5 major neighbours and hence v can be adjacent with at most one minor vertex other than the 3-vertex u , which is a

contradiction to (i). Hence, no major vertex has a vertex of $\mathcal{N}_3$ as its neighbourand hence that $\mathcal{N}_3=\phi$. Hence $\delta=4$. Suppose a vertex in $\mathbb{M}$(say v) has a vertex $u'\in V(\mathcal{N}_4)$ and a vertex $u''\in V(\mathcal{N}_5)$ as its neighbours. From result 3.2 and (ii), u' and u'' are adjacent and v cannot have a vertx in $\mathcal{N}_6$as its neighbour. Hence no major vertex has a vertex in $\mathcal{N}_6$ as its neighbour. Hence $\mathcal{N}_6=\phi$. Thus, $\mathbb{M}=\mathbb{M}_{45}$ and $n=|\mathcal{N}_4|+|\mathcal{N}_5|+|\mathbb{M}_{45}|$.Also, $|[\mathcal{N}_4,\mathcal{N}_5]|=n_4$, $|[\mathcal{N}_4,\mathbb{M}_{45}]|=3n_4$ and $|[\mathcal{N}_5,\mathbb{M}_{45}]|=4n_5$. Since each major vertex has exactly one4_vertex, one 5_vertex and five major vertices as its neighbours, $n_7=\frac{1}{2}[\,|[\mathcal{N}_4,\mathbb{M}_{45}]|+|[\mathcal{N}_5,\mathbb{M}_{45}]|]$. (i.e.) $n_7=\frac{3n_4+4n_5}{2}=\frac{3}{2}n_4+2n_5$. Since $n_4=n_5$, $n_7=\frac{7}{2}n_4=\frac{7}{2}n_5$. Since each major vertex hasexactly five vertices in $\mathbb{M}$ as its neighbours, $|[\mathbb{M},\mathbb{M}]|=\frac{5n_7}{2}=\frac{5}{2}\left(\frac{3}{2}n_4+2n_5\right)=\frac{15}{4}n_4+5n_5$. Hence $m=|[\mathcal{N}_4,\mathcal{N}_5]|+|[\mathcal{N}_4,\mathbb{M}_{45}]|+|[\mathcal{N}_5,\mathbb{M}_{45}]|+|[\mathbb{M},\mathbb{M}]|=$

$$n_4+3n_4+4n_5+\frac{15}{4}n_4+5n_5=\left(4+\frac{15}{4}\right)n_4+9n_5=\frac{31}{4}n_4+9n_5=3n+\left(\frac{31}{4}-3\right)n_4+6n_5-3n_7=$$

$$3n+\frac{19}{4}n_4+6n_5-3\left(\frac{3}{2}n_4+2n_5\right)=3n+\frac{1}{4}n_4.$$ Since $n_4=n_5$, $m=3n+\frac{1}{4}n_5$.

■

Observation 4.2: There is no edge chromatic 7-critical graph with $\delta=2$ or 3 such that(i) each vertex in $\mathbb{M}$ has a vertex in $\mathcal{N}_4$and a vertex in $\mathcal{N}_5$as its neighbours and (ii) every vertex in $\mathcal{N}_4$has a vertex in $\mathcal{N}_5$as its neighbour and vice versa.

Observation 4.3: In the theorem 4.1,if $n_4>6$, then $m>3n+\frac{3}{2}$ which improves the bound given by Vizing on the size.

Observation 4.4: In the theorem 4.1, the number of major vertices = $n_7=\frac{3}{2}n_4+2n_5=\frac{7}{2}n_4=\frac{7}{2}n_5$, which is an improved counton n_Δ given by Limin Zhang[3].

Theorem 4.5: Let $\mathcal{G}$ be an edge chromatic 7-critical graph such that (i)every vertex in $\mathcal{N}_6$ has a vertex in $\mathcal{N}_3$ as its neighbour (ii) every vertex in $\mathcal{N}_5$ has a vertex in $\mathcal{N}_4$ as its neighbour and (iii) for every major vertex v, $\mathcal{N}(v)\bigcap\mathcal{N}_i\bigcap\mathcal{N}_j=\phi$ for all $i\neq j$. Then $n_7\geq 2n_2+\frac{3}{2}n_3+\frac{4}{3}n_4+\frac{2}{3}n_5+\frac{1}{2}n_6$ and $m\geq 8n_2+\frac{27}{4}n_3+\frac{20}{3}n_4+\frac{29}{6}n_5+\frac{19}{4}n_6$.

Proof: By (i) , (ii) and VAL, every 6_vertex has five neighboursin $\mathbb{M}$and every vertex in $\mathcal{N}_5$ has exactly four major neighbours. Hence$|[\mathcal{N}_6,\mathbb{M}]|=5n_6$ and $|[\mathcal{N}_5,\mathbb{M}]|=4n_5$. Let $\mathcal{N}^*_3$denote the collection of all vertices in $\mathcal{N}_3$ which have neighbours in $\mathcal{N}_6$ and let $\mathcal{N}^{**}_3=\mathcal{N}_3-\mathcal{N}^*_3$. From (i) and VAL, all vertices in $\mathcal{N}_6$ have exactly one neighbour in $\mathcal{N}_3$ and all vertices in $\mathcal{N}_3$ haveat least two neighbours in $\mathbb{M}$. Hence $|\mathcal{N}^*_3|=n_6$ and $|\mathcal{N}^{**}_3|=n_3-n_6$. By VAL, we have $|[\mathcal{N}^*_3,\mathbb{M}]|=2n_6$ &$|[\mathcal{N}_2,\mathbb{M}]|=2n_2$. Also, $|[\mathcal{N}_6,\mathcal{N}^*_3]|=n_6$. Let$\mathcal{N}^*_4$denote the collection of all vertices in $\mathcal{N}_4$thathave their neighbours in $\mathcal{N}_5$ and $\mathcal{N}^{**}_4=\mathcal{N}_4-\mathcal{N}^*_4$. From (ii) and VAL, each 5_vertexhas exactly one neighbour in $\mathcal{N}_4$ and hence $|\mathcal{N}^*_4|=n_5$ &$|\mathcal{N}^{**}_4|=n_4-n_5$. From result 3.1,$|[\mathcal{N}^*_4,\mathbb{M}]|=3n_5$. By VAL, $[\mathcal{N}_3,\mathcal{N}_4]=[\mathcal{N}_3,\mathcal{N}_5]=\phi$ and hence $|[\mathcal{N}_3,\mathcal{N}_4]|=|[\mathcal{N}_3,\mathcal{N}_5]|=0$ and $|[\mathcal{N}^{**}_3,\mathbb{M}]|=3(n_3-n_6)$. Fromthe result 3.2,$|[\mathcal{N}^{**}_3,\mathcal{N}_6]|=0$ and $|[\mathcal{N}^{**}_4,$

$\mathcal{N}_6]|=0$. By (i) , (ii) and result 3.2, $|[\mathcal{N}_4,\mathcal{N}_6]|=|[\mathcal{N}_5,\mathcal{N}_6]|=0$. By VAL, $|[\mathcal{N}_4]|=0$. Also, $[\mathcal{N}^{**}_4, \mathcal{N}_5]=\phi$ and $|[\mathcal{N}^{**}_4, \mathbb{M}]| = 4(n_4 - n_5)$. Let $\mathcal{N}$represent the collection of all minor vertices in$\mathcal{G}$. $|[\mathcal{N}, \mathbb{M}]| = 2n_2 + 2n_6 + 3(n_3 - n_6) + 3n_5 + 4(n_4 - n_5) + 4n_5 + 5n_6 = 2n_2 + 3n_3 + 4n_4 + 4n_6 + 3n_5$. Also, $|[\mathcal{N},\mathcal{N}]|=|[\mathcal{N}_6,\mathcal{N}^*_3]|+|[\mathcal{N}_5, \mathcal{N}^*_4]| = n_6 + n_5$. From (iii),$\mathbb{M}=\bigcup_{i=2}^{6} \mathbb{M}_i \cup \mathbb{M}^*$, $\mathbb{M}^*$ represents the collection of all vertices in $\mathbb{M}$which have no minor neighbours. Since$|[\mathcal{N}_2,\mathbb{M}]| = 2n_2$, by VAL, $|\mathbb{M}_2| = 2n_2$. $|[\mathcal{N}_3,\mathbb{M}]| = 2n_6 + 3(n_3 - n_6) = 3n_3 - n_6$. A vertex in $\mathbb{M}$which has a neighbour in $\mathcal{N}_3$should have at least five major neighbours. Hence$|\mathbb{M}_3| \geq \frac{3n_3 - n_6}{2}$.

$|[\mathcal{N}_4, \mathbb{M}]| = 3n_5 + 4(n_4 - n_5) = 4n_4 - n_5$. A vertex in $\mathbb{M}$ which has a 4_vertex as its neighbour should have at least four major neighbours. Thus $|\mathbb{M}_4| \geq \frac{4n_4 - n_5}{3}$. Also, $|[\mathcal{N}_5, \mathbb{M}]| = 4n_5$. A vertex in $\mathbb{M}$which has a neighbour in $\mathcal{N}_5$ should have at least three major neighbours. Thus,

$|\mathbb{M}_5| \geq n_5$. Also, $|[\mathcal{N}_6, \mathbb{M}]| = 5n_6$. Hence $|\mathbb{M}_6| \geq \frac{5n_6}{5} = n_6$. Hence $n_7 \geq |\mathbb{M}_2|_+|\mathbb{M}_3|_+|\mathbb{M}_4|+|\mathbb{M}_5|+|\mathbb{M}_6|$ $\geq 2n_2 + \frac{3}{2}n_3 - \frac{1}{2}n_6 + \frac{4n_4}{3} - \frac{n_5}{3} + n_5 + n_6$. Hence $n_7 \geq 2n_2 + \frac{3n_3}{2} + \frac{4n_4}{3} + \frac{2n_5}{3} + \frac{n_6}{2}$. Also,$|[\mathbb{M},\mathbb{M}]|$ $\geq \frac{1}{2}[6(2n_2) + 5\left(\frac{3}{2}n_3 - \frac{1}{2}n_6\right) + 4\left(\frac{4}{3}n_4 - \frac{1}{3}n_5\right) + 3n_5 + 2n_6] = 6n_2 + \frac{15}{4}n_3 + \frac{8}{3}n_4$ $+ \left(\frac{3}{2} - \frac{2}{3}\right)n_5 + \left(1 - \frac{5}{4}\right)n_6$ .Hence $|[\mathbb{M},\mathbb{M}]| \geq 6n_2 + \frac{15}{4}n_3 + \frac{8}{3}n_4 + \frac{5}{6}n_5 - \frac{1}{4}n_6$. Now, $m \geq$ $|[\mathcal{N},\mathcal{N}]|+|[\mathcal{N},\mathbb{M}]|+|[\mathbb{M},\mathbb{M}]|$. Hence $m \geq n_6 + n_5 + 2n_2 + 3n_3 + 4n_4 + 4n_6 + 3n_5 + 6n_2 + \frac{15}{4}n_3 + \frac{8}{3}n_4 + \frac{5}{6}n_5$ $- \frac{1}{4}n_6 = 8n_2 + \frac{27}{4}n_3 + \frac{20}{3}n_4 + \frac{29}{6}n_5 + \frac{19}{4}n_6$. ■

Observation 4.6: In the theorem 4.5, $2m = 2n_2 + 3n_3 + 4n_4 + 5n_5 + 6n_6 + 7n_7 = 6n - 4n_2 - 3n_3$ $- 2n_4 - n_5 + n_7 \geq 6n - 4n_2 - 3n_3 - 2n_4 - n_5 + 2n_2 + \frac{3}{2}n_3 + \frac{4}{3}n_4 + \frac{2}{3}n_5 + \frac{1}{2}n_6 = 6n - 2n_2 - \frac{3}{2}n_3 -$ $\frac{2n_4}{3} - \frac{n_5}{3} + \frac{n_6}{2}$. Hence $m \geq 3n - n_2 - \frac{3}{4}n_3 - \frac{n_4}{3} - \frac{n_5}{6} + \frac{1}{4}n_6$. Hence $m > 3n + \frac{3}{2}$ if $\frac{1}{4}n_6 - n_2$ $- \frac{3}{4}n_3 - \frac{1}{3}n_4 - \frac{1}{6}n_5 > \frac{3}{2}$. Thus the bound given by Vizing on the size is improved if $n_6 > 4n_2 + 3n_3 + \frac{4}{3}n_4 + \frac{2}{3}n_5 + 6$.

Observation 4.7: On comparing the bound on n_Δ obtained in theorem 4.5 with the existing bound[3], the improvement obtained in $n_\Delta = \left(\frac{4}{3} - \frac{2}{3}\right)n_4 + \left(\frac{2}{3} - \frac{1}{2}\right)n_5 + \left(\frac{1}{2} - \frac{2}{5}\right)n_6 = \frac{2}{3}n_4 + \frac{1}{6}n_5 + \frac{1}{10}n_6$.

Theorem 4.8: If an edge chromatic 7-critical graph satisfies the conditions that (i)every vertex in $\mathcal{N}_6$ has a neighbour in $\mathcal{N}_3$ (ii) every 5-vertex has a 4_vertex as its neighbourand (iii) every major vertex has at most one minor vertex as its neighbour, then $n_7 \geq 2n_2 + 3n_3 + 4n_4 + 3n_5 + 4n_6$ and $m \geq 8n_2 + 12n_3 + 16n_4 + 13n_5 + 17n_6$.

Proof: Since each major vertex has at most one minor vertex as its neighbour, by a similar argument as in the theorem 4.5, we obtain that $|\mathbb{M}_3| = 3n_3 - n_6$, $|\mathbb{M}_4| = 4n_4 - n_5$, $|\mathbb{M}_5| = 4n_5$ and $|\mathbb{M}_6| = 5n_6$. Hence $n_7 \geq |\mathbb{M}_2| + |\mathbb{M}_3| + |\mathbb{M}_4| + |\mathbb{M}_5| + |\mathbb{M}_6| \geq 2n_2 + 3n_3 - n_6 + 4n_4 - n_5 + 4n_5 + 5n_6$. Hence $n_7 \geq 2n_2 + 3n_3 + 4n_4 + 3n_5 + 4n_6$. Also, $|[\mathbb{M},\mathbb{M}]| \geq 3[2n_2 + 3n_3 - n_6 + 4n_4 - n_5 + 4n_5 + 5n_6] = 3[2n_2 + 3n_3 + 4n_4 + 3n_5 + 4n_6] = 6n_2 + 9n_3 + 12n_4 + 9n_5 + 12n_6$. Now, $m = |[\mathcal{N},\mathcal{N}]| + |[\mathcal{N}, \mathbb{M}]| + |[\mathbb{M}, \mathbb{M}]| \geq n_6 + n_5 + 2n_2 + 3n_3 + 4n_4 + 4n_6 + 3n_5 + 6n_2 + 9n_3 + 12n_4 + 9n_5 + 12n_6$. Hence $m \geq 8n_2 + 12n_3 + 16n_4 + 13n_5 + 17n_6$.

■

Observation 4.9: In the theorem 4.8, $2m = 2n_2 + 3n_3 + 4n_4 + 5n_5 + 6n_6 + 7n_7 = 6n - 4n_2 - 3n_3 - 2n_4 - n_5 + n_7 \geq 6n - 4n_2 - 3n_3 - 2n_4 - n_5 + 2n_2 + 3n_3 + 4n_4 + 3n_5 + 4n_6 = 6n - 2n_2 + 2n_4 + 2n_5 + 4n_6$. Hence $m \geq 3n - n_2 + n_4 + n_5 + 2n_6$. Hence $m > 3n + \frac{3}{2}$ if $2n_6 + n_5 + n_4 - n_2 > \frac{3}{2}$. Thus the bound given by Vizing on the size is improved if $2n_6 + n_5 + n_4 - n_2 > \frac{3}{2}$. Hence , the bound on size is improved in the cases: (i) $n_6 \geq 1$ & $n_2 = 0$ (ii) $n_5 \geq 1$ & $n_2 = 0$ & (iii) $n_4 > 1$ & $n_2 = 0$.

Observation 4.10: On comparing the bound on n_Δ obtained in theorem 4.8 with the existing bound[3], the improvement obtained in $n_\Delta = \frac{3}{2}n_3 + \frac{10}{3}n_4 + \frac{5}{2}n_5 + \frac{18}{5}n_6$.

Theorem 4.11: There is no 7-critical graph such that $|[\mathcal{N}_5]|=0$ and every vertex in $\mathbb{M}$ has a vertex in $\mathcal{N}_3$ and also a vertex in $\mathcal{N}_5$ as its neighbours.

Proof: Suppose there is a 7-critical graph with $|[\mathcal{N}_5]|=0$ and every vertex in $\mathbb{M}$ has a vertex in $\mathcal{N}_3$ and also a vertex in $\mathcal{N}_5$ as its neighbours. Hence $\mathbb{M}_2=\mathbb{M}_3=\mathbb{M}_4=\circledcirc_5=\circledcirc_6=\phi$. Since each major vertex has 3_vertex and also a 5_vertex as its neighbours, by VAL, $\circledcirc=\circledcirc_{35}$. Hence, $\circledcirc_2=\circledcirc_4=\circledcirc_6=\phi$. Thus, $\delta = 3$ and $n = n_3 + n_5 + n_7$. By VAL, any vertex in $\circledcirc_3$ cannot have a neighbour in $\circledcirc_5$. Hence $|[\circledcirc_3,\circledcirc_5]|=0$. Thus $|[\circledcirc_3,\circledcirc]| = 3n_3$. Since $|[\circledcirc_5]|=0$, every 5_vertex has five major neighbours and $|[\circledcirc_5,\circledcirc_{35}]| = 5n_5$. Since each vertex in $\circledcirc$ has exactly one vertex in $\circledcirc_3$ and one vertex in $\mathcal{N}_5$ and five vertices in $\mathbb{M}$ as its neighbours, $n_7 = |\mathbb{M}_{35}| = \frac{3n_3 + 5n_5}{2}$. Now, $n = n_3 + n_5 + n_7 = n_3 + n_5 + \frac{3n_3}{2} + \frac{5n_5}{2} = \frac{5n_3}{2} + \frac{7n_5}{2}$. Also, $m = |[\mathcal{N}_3,\mathbb{M}_{35}]| + |[\mathcal{N}_5]| + |[\mathcal{N}_5,\mathbb{M}_{35}]| + |[\mathbb{M}]|$. As there are exactly 5 major neighbours for each vertex in $\mathbb{M}$, $|[\mathbb{M}]| = \frac{5n_7}{2} = \frac{5}{2}\left(\frac{3}{2}n_3 + \frac{5}{2}n_5\right) = \frac{15}{4}n_3 + \frac{25}{4}n_5$. Hence $m = 3n_3 + 5n_5 + \frac{15}{4}n_3 + \frac{25}{4}n_5 = \frac{27}{4}n_3 + \frac{45}{4}n_5$. Since each vertex in $\mathbb{M}$ has exactly one vertex in $\mathcal{N}_3$ and one vertex in $\mathcal{N}_5$ and five vertices in $\mathbb{M}$ as its neighbours, $|[\mathcal{N}_3,\mathbb{M}]| = |[\mathcal{N}_5,\mathbb{M}]|$. Hence $3n_3 = 5n_5$. Thus $n_3 = \frac{5}{3}n_5 > n_5$.(i.e.) $n_3 > n_5$ .By result 3.3, $2m \geq 6n$.

Hence $\frac{27}{2}n_3+\frac{45}{2}n_5 \geq 6\left(\frac{5}{2}n_3+\frac{7}{2}n_5\right) \Rightarrow \left(\frac{27}{2}-15\right)n_3 \geq \left(21-\frac{45}{2}\right)n_5 \Rightarrow -\frac{3}{2}n_3 \geq -\frac{3}{2}n_5 \Rightarrow n_3 \leq n_5$

, which is a contradiction. Thus, there is no 7-critical graph such that $|[\mathcal{N}_5]|=0$ and each vertex in $\mathbb{M}$ has a vertex in $\mathcal{N}_5$and a vertex in $\mathcal{N}_3$ as its neighbours. ■

Observation 4.12: For any edge-chromatic 7-critical graph such that eachvertexin $\mathbb{M}$has a vertex in $\mathcal{N}_3$ and also a vertex in $\mathcal{N}_5$as its neighbours, $|[\mathcal{N}_5]| \neq 0$.

Observation 4.13: For any edge-chromatic 7-critical graph with with$|[\mathcal{N}_5]|=0$, there exists a major vertex which is either 'nonadjacent with every 3_vertices' or 'nonadjacent with every 5_vertices'.

CONCLUSION

This article gives insights on three kinds of families of edge-chromatic critical graphs. The improvements are listed below.

The nature of edge chromatic 7- critical graphs	Existing known bound on n_Δ and m [2,3]	The bound obtained in this article	The cases in which the improvement on m is attained	The improvement on n_Δ
edge-chromatic critical graphs with the conditions of theorem 4.1	$n_\Delta \geq 2n_2+\frac{3}{2}n_3+\frac{2}{3}n_4+\frac{1}{2}n_5+\frac{2}{5}n_6$ $m \geq (1/2)[(\Delta-1)n+3]$	$n_7=\frac{3}{2}n_4+2n_5$ and $m=3n+\frac{1}{4}n_4$.	$n_4>6$	$(7/3)n_5$
edge-chromatic critical graphs with conditions in theorem 4.5		$n_7 \geq 2n_2+\frac{3}{2}n_3+\frac{4}{3}n_4+\frac{2}{3}n_5+\frac{1}{2}n_6$ and $m \geq 8n_2+\frac{27}{4}n_3+\frac{20}{3}n_4+\frac{29}{6}n_5+\frac{19}{4}n_6$.	$n_6>4n_2+3n_3+(4/3)n_4+(2/3)n_5+6$	$(2/3)n_4+(1/6)n_5+(1/10)n_6$
edge-chromatic critical graphs with conditions in theorem 4.8		$n_7 \geq 2n_2+3n_3+4n_4+3n_5+4n_6$ and $m \geq 8n_2+12n_3+16n_4+13n_5+17n_6$.	$2n_6+n_5+n_4-n_2>\frac{3}{2}$	$\frac{3}{2}n_3+\frac{10}{3}n_4+\frac{5}{2}n_5+\frac{18}{5}n_6$

ABSTRACT

In order to prevent antibiotic resistance, urinary tract infections (UTIs) are a significant worldwide health concern that must be promptly diagnosed. The shift from traditional urine culture to advanced molecular, point-of-care (POCT), and artificial intelligence (AI) diagnostics is assessed in this review. With an emphasis on "UTI diagnostics," "molecular methods," and "AI in microbiology," a thorough literature search was carried out utilizing databases such as Medline (MeSH), PubMed, and Google Scholar for articles published between 1990 and 2026. The investigation demonstrates how uropathogens and antimicrobial resistance (AMR) genes may be quickly and independently identified using molecular approaches like PCR, LAMP, and metagenomic sequencing (mNGS). We also go over how AI-driven predictive modeling and biosensor-based POCT improve diagnostic precision and laboratory productivity. By making early, focused treatment possible, these developments promote antimicrobial stewardship. Despite advancements in technology, issues like high costs, a lack of standardization, and the requirement for clinical validation continue to be major obstacles to wider adoption. All things considered, incorporating these advancements is crucial for creating individualized and data-driven UTI diagnostic approaches.

Keywords: Urinary Tract Infections (UTI); Polymerase chain reaction (PCR); Loop-mediated isothermal amplification (LAMP); Point-of-care testing (POCT); Artificial intelligence (AI); Antimicrobial stewardship (AS)

INTRODUCTION

Among the most prevalent bacterial illnesses, urinary tract infections (UTIs) afflict people of all ages and genders, but they are more common in women and older adults [1]. A prompt and precise diagnosis of UTIs is crucial. Targeted treatment, which lowers the risk of major consequences such pyelonephritis, urosepsis, and recurrent infections, is made possible by early infection detection. However, the view must also be accurate because nonspecific lower urinary tract symptoms might result in an empirical over prescription of antibiotics, which can cause unjustified side events and antimicrobial resistance (AMR) [2]. Recent decades' epidemiological data clearly show that UTIs are becoming a global issue. A notable example is a study that compared the prevalence of these illnesses between 1990 and 2019 and found that the number of cases worldwide had increased by 60% [3]. Scary figures are emerging from vibrant parts of the globe. Approximately 10.5 million patient visits, 3 million visits to emergency rooms, and 400,000 hospital admissions were caused by UTIs in the US each year. The health system had to pay a staggering 4.8 billion dollars a year due to this level of infection [4, 5, and 6]. Inversely, the European scenario is worrisome [7, 8, and 9]. In contrast to pyelonephritis, which is identified by systemic symptoms like fever and flank pain, acute uncomplicated cystitis is generally diagnosed clinically based on symptoms like dysuria, frequency, and urgency. Urine culture is still the gold standard for diagnosis, but it is frequently impractical to use it on a regular basis for simple lower urinary tract infections (UTIs). A UTI can be diagnosed with 90% accuracy in healthy women if two or more clinical symptoms are present [10]. Although urinalysis is a vital technique for identifying bacteriuria and pyuria, its specificity ranges from 42% to 90%, requiring a confirmation urine culture in complex or recurrent cases [11].

The correlation between inadequate diagnosis and the rise of antimicrobial resistance (AMR) is multifaceted. Key factors include:

- **False Positives:** Prescription of antibiotics for symptoms not caused by an actual infection.
- **False Negatives:** Delayed treatment leading to the eventual necessity for high-potency, prolonged antibiotic courses.
- **Inadequate Selection:** Poor identification of target pathogens resulting in suboptimal therapeutic choices.

Novel diagnostic methods that make use of developments in molecular biology, biosensors, artificial intelligence (AI), and point-of-care testing (POCT) have been developed to overcome these constraints. When compared to conventional culture, molecular techniques like polymerase chain reaction (PCR) allow for the quick and more accurate detection of bacterial DNA [12]. These techniques are especially useful for detecting slow-growing or picky organisms that are frequently missed by traditional cultures. Additionally, POCT devices eliminate the need for centralized laboratory facilities by enabling prompt bedside diagnosis [13]. With an emphasis on the combination of POCT, AI, and molecular diagnostics to improve antimicrobial stewardship and diagnostic accuracy, this review seeks to assess these recent advancements.

Pathophysiology of Urinary Tract Infection

A highly coordinated ascending cascade is required to convert the urinary tract from a low-biomass, homeostatic milieu into an active zone of infection. Certain microbial virulence factors that get past host immune systems and anatomical barriers are what propel this process [14].

Microbial Translocation and Urethral Colonization

Urinary tract infections (UTIs) usually start off as opportunistic phenomena [18]. To colonize the periurethral mucosa, microorganisms move from anatomical reservoirs, mainly the gastrointestinal system, perineum, or vagina [18, 19]. Uropathogens must ascend the urethra after becoming established in the periurethral region in order to enter the bladder lumen [14]. The host's main mechanical defense mechanism is the continuous hydrodynamic flushing of urine, which the pathogens must overcome in order to migrate [20].

Adherence and Bladder Invasion

Uropathogens use specific surface organelles called chaperone-usher fimbriae to survive urine flow [21]. Type 1 fimbriae are typically expressed by Uropathogenic Escherichia coli (UPEC), the primary etiological agent accountable for the great majority of instances worldwide [22, 23]. These fimbriae's adhesive tip, a lectin called FimH, has a strong affinity for mannosylated uroplakin receptors (UPIa and UPIb) that line the bladder epithelium's superficial umbrella cells [24] On the other hand, pathogens such as Pseudomonas aeruginosa, Proteus mirabilis, and Klebsiella pneumoniae use specific pili and surface adhesins to attach directly to host tissues or foreign biomaterials in complicated UTIs (cUTIs) involving structural abnormalities or indwelling urinary catheters [25, 26].

Intracellular Niche Activation and Biofilm Formation

Actin cytoskeleton rearrangements occur in the host cell membrane upon successful adhesion, allowing the associated bacterium to be engulfed through receptor-mediated endocytosis [27]. After entering the superficial facet cells' cytoplasm, UPEC quickly multiplies to create structured clusters known as Intracellular Bacterial Communities (IBCs) [26].

- Uropathogens adopt an extracellular lifestyle and create a protective Extracellular Polymeric Substance (EPS) matrix as the infection worsens or when foreign objects such indwelling catheters are present [28]. This biofilm structure fulfills a number of vital purposes:
  It physically prevents systemic antibiotic penetration by the reproducing microorganisms [28].
- It shields the pathogens from recognition by host immune cells [29].
- It facilitates sustained colonization, acting as a permanent microbial reservoir that drives recurrent infections (rUTIs) and chronic persistence [18, 22].

Host proteins such as fibrinogen quickly adhere to the artificial lumen in catheterized environments [30]. By generating urease, an enzyme that hydrolyzes urea into ammonia, pathogens such as P. mirabilis take advantage of this environment. Struvite and apatite crystals, which are calcium and magnesium phosphates, precipitate as a result of the local pH rising [31]. By encasing the bacterial biofilm, these crystals create crystalline encrustations that obstruct catheter flow and are resistant to traditional antimicrobial treatments [30, 31].

Host Innate Immune Mobilization and Tissue Damage

Toll-like receptors (mostly TLR4 and TLR5) expressed on the urothelium are activated when uropathogens invade cells and multiply, triggering the host's innate immune system [32]. Nuclear factor kappa B (NF-KB) is nuclear translocated as a result of this ligand binding, which starts an intracellular signaling cascade driven by myeloid differentiation factor 88 (MyD88) [32, 33].

- Strong transcription and secretion of pro-inflammatory cytokines and chemokines, particularly Interleukin-6 (IL-6) and Interleukin-8 (IL-8), are driven by NF-KB activation [33]
- IL-6 modulates localized acute-phase inflammatory responses [33].

Clinical pyuria is caused by IL-8 creating a potent chemical gradient that draws polymorph nuclear neutrophils (PMNs) from the vasculature and into the bladder lumen [14, 34]. Uropathogens simultaneously release cytotoxic poisons to meet their metabolic requirements and make room for further tissue spread [21]. For instance, significant amounts of the pore-forming toxin \alpha-hemolysin (HlyA), which lyses host cell membranes, are released by UPEC strains [19]. The bladder mucosa is greatly exfoliated as a result, giving the bacteria access to deeper, underlying cell layers [27, 35]. In order to scavenge ferric iron from host proteins and support fast bacterial metabolism, the bacteria simultaneously release high-affinity iron chelators known as siderophores, such as enterobactin and aerobactin [21, 36].

Kidney Ascension and Systemic

TranslocationUropathogens climb the ureters to infect the upper urinary system if targeted therapy or host defenses fail to eradicate the localized bladder infection [14]. By attaching to digalactoside residues produced on renal epithelial cells, P fimbriae (mediated by the PapG adhesin) are essential for kidney ascent [21, 37]. Acute

pyelonephritis, which is marked by severe interstitial inflammation, renal parenchymal destruction, and a high risk of bacterial translocation across the renal vascular endothelium into the bloodstream—which can result in potentially fatal urosepsis—is brought on by this interaction [37, 38].

Molecular Diagnostic

By facilitating the quick and accurate identification of uropathogens directly from urine samples, molecular diagnostic techniques have significantly improved the diagnosis of urinary tract infections (UTIs) [39, 40]. Common uropathogens like *Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, Enterococcus spp.,* and *Staphylococcus saprophyticus* can be identified early using nucleic acid amplification tests, especially polymerase chain reaction (PCR)-based assays, which considerably shorten turnaround times when compared to traditional culture [39, 41].

Polymerase Chain Reaction

Advances in PCR technology, including as multiplex PCR panels and real-time PCR (qPCR), have significantly enhanced the diagnostic utility of molecular testing in UTIs. By identifying infections and identifying antibiotic resistance genes, such as those encoding carbapenems and extended-spectrum β-lactamases (ESBLs), these techniques support antimicrobial stewardship initiatives. PCR-based diagnostics have disadvantages despite their advantages, such as high cost, limited availability in routine labs, and the inability to distinguish between colonization and active infection. However, when paired with clinical assessment and conventional microbiology, PCR is a helpful addition to the comprehensive diagnosis and treatment of UTIs [42, 43].This is especially helpful for complex UTIs, where successful therapy depends on identifying the right bacteria and its resistance profile.

Metagenomic Next-Generation Sequencing (mNGS)

A sophisticated molecular diagnostic technique called metagenomic next-generation sequencing (mNGS) allows for the thorough, culture-independent identification of every microbial nucleic acid found in a clinical material [44, 45]. mNGS makes it easier to simultaneously identify bacteria, viruses, fungi, and parasites—including uncommon, picky, and uncultivable organisms—by doing away with the need for specialized primers. When treating illnesses that are difficult to diagnose and when traditional culture or focused molecular tests produce negative or ambiguous findings, this objective approach is very helpful [44]. Precision antimicrobial therapy is supported by mNGS, which offers vital information on polymicrobial illnesses and antimicrobial resistance (AMR) determinants in addition to wide pathogen detection [46]. Clinical adoption is still constrained by high operating costs, computational complexity, and the difficulties in differentiating clinically meaningful data from background microbiota or environmental contamination, despite its substantial diagnostic potential. However, it is anticipated that further developments in analytical pipelines and sequencing technology will improve the clinical value of mNGS in the field of molecular diagnostics [44, 45].

Loop-Mediated Isothermal Amplification (LAMP)

A potential molecular method for the microbiological and molecular detection of urinary tract infections (UTIs) is loop-mediated isothermal amplification (LAMP). Using a set of four to six primers that identify various target gene areas, LAMP allows for the quick amplification of target nucleic acids under isothermal conditions (60–65°C). Without the need for complex heat cyclers, this design's excellent analytical sensitivity and specificity enable the direct identification of major uropathogens from urine samples, including *Escherichia coli, Klebsiella pneumoniae,* and *Enterococcus spp*. LAMP dramatically shortens turnaround times when compared to traditional culture and PCR-based techniques, frequently producing findings in 30 to 60 minute—a crucial component for early diagnosis and prompt antibiotic treatment [46]. LAMP has recently been combined with colorimetric, turbidimetric, and fluorescence-based readouts to enable point-of-care testing (POCT) and use in environments with limited resources. Antimicrobial stewardship is further supported by the ability for simultaneous pathogen identification and antimicrobial resistance (AMR) determinant detection demonstrated by multiplex and resistance-gene-targeted LAMP tests. Notwithstanding these benefits, problems including uniformity, contamination risk, and limited quantitative capacity still exist. However, LAMP is a useful, economical, and therapeutically significant contribution to the developing field of molecular diagnostics for UTIs [47].

Identifying AMR with Molecular Methods

The detection of antimicrobial resistance (AMR) via molecular techniques is now crucial for treating urinary tract infections (UTIs) due to advances in microbiological and molecular diagnostics. Molecular methods enable the quick identification of resistance-related genes directly from urine tests or positive culture samples by avoiding the delays connected with phenotypic susceptibility testing.

Key resistance determinants include:

- **Extended-spectrum β-lactamase (ESBL) genes:** bla(CTX-M), bla(TEM), bla(SHV).
- **Carbapenemase genes:** bla(KPC), bla(NDM), and bla(OXA-48).
- **Quinolone resistance:** Plasmid-mediated resistance genes in uropathogens such as *Escherichia coli* and *Klebsiella pneumoniae*.

These techniques greatly shorten turnaround times, allowing for early antimicrobial treatment optimization and better patient outcomes [48]. The use of microarrays, syndromic molecular panels, and next-generation sequencing (NGS) for thorough AMR profiling are examples of recent advancements. The simultaneous identification of bacteria and their "resistome," even in polymicrobial or culture-negative UTIs, is made possible by met genomic methods.

Some limitations still exist despite great sensitivity and specificity, such as the incapacity of molecular techniques to assess gene expression, discover new resistance mechanisms, or assess phenotypic significance. However, molecular methods are becoming more and more important in guiding antimicrobial stewardship programs, infection prevention, and focused therapy, which is a significant development in the management of UTIs [49].

Point-of-Care testing

Without the need for centralized laboratory infrastructure, point-of-care testing (POCT) provides quick, on-site pathogen and biomarker identification. Urine dipstick tests have been widely used as a major POCT method because of its simplicity, affordability, and convenience of use. However, their poor specificity frequently leads to over diagnosis and overtreatment [50]. Moreover, laboratory-based confirmatory testing is usually required since these tests cannot differentiate between different uropathogens or offer information on antimicrobial resistance (AMR) trends.

Alternatives to Traditional Dipsticks

The creation of alternatives to conventional dipsticks is a major advancement in the microbiological and molecular detection of urinary tract infections (UTIs). Leukocyte esterase and nitrites are detected by conventional dipstick tests, but they have low sensitivity and specificity, especially in early-stage infections, low bacterial counts, or infections brought on by species that do not produce nitrites. New biosensor-based tests and molecular urine screening instruments have been created to get over these restrictions by directly identifying:

- Nucleic acids unique to pathogens.
- Biomarkers of host inflammation.
- Particular components of bacteria.

By increasing diagnostic accuracy and drastically lowering false-negative results, these sophisticated techniques allow for earlier and more accurate UTI diagnosis as compared to traditional dipstick testing [51].

Dip-Slides and Culture Kits

For the microbiological diagnosis of urinary tract infections (UTIs), dip-slides and commercial culture kits are useful substitutes for traditional laboratory urine culture. Dip-slide devices provide semi-quantitative measurement of bacterial load and presumed pathogen identification by submerging plastic paddles covered with culture medium in urine and incubating them. These kits offer an affordable and user-friendly solution, especially in primary care, outpatient settings, and resource-constrained areas where access to thorough microbiological laboratories may be limited. Dip-slides provide an appropriate sensitivity for identifying substantial bacteriuria while reducing handling steps and turnaround time when compared to traditional culture procedures [52]. Traditional dipsticks are not

currently recommended by Public Health England and the National Institute for Health and Care Excellence (NICE) for the diagnosis of UTIs, with the exception of females under 65 who present with mild to moderate symptoms [53,54]. This is consistent with other research showing that dipsticks are quite useful for ruling out UTIs in premenopausal women in non-hospital settings using clean midstream urine samples; however, their diagnostic accuracy among hospitalized or convalescent patients is still unknown [55–58].

In order to make interpretation simpler, recent advancements in commercial culture kits have concentrated on better chromogenic medium, increased selectivity, and more distinct colony differentiation. To improve diagnostic coverage, some kits have dual media surfaces that promote the development of both Gram-positive and Gram-negative uropathogens. Dip-slides and culture kits are still useful for screening, epidemiological surveillance, and the monitoring of recurring UTIs, even if they cannot take the place of sophisticated molecular diagnostics in terms of speed or resistance detection. Their enduring significance alongside more recent molecular and automated technologies is demonstrated by their incorporation into contemporary diagnostic algorithms [59].

Biosensors and Emergent Technologies

The use of biosensor technology in POCT has led to the development of extremely sensitive and accurate UTI detection methods. Electrochemical biosensors employing nonmaterial and microfluidic devices may identify host response markers, volatile organic compounds, and bacterial metabolic by products in urine [39].

Artificial Intelligence (Ai)

Urinary tract infection (UTI) microbiological and molecular diagnostics are rapidly incorporating artificial intelligence (AI) to improve clinical decision-making, speed, and accuracy. Complex datasets produced by urine microscopy, flow cytometry, imaging, and molecular diagnostic platforms are analyzed using AI-driven techniques, such as machine learning and deep learning models. These methods can forecast the presence of pathogens, quickly differentiate between contaminated samples and actual illnesses, and assist in the early triage of urine specimens for genetic testing or culture.AI increases workflow efficiency and shortens diagnostic turnaround times in high-volume clinical laboratories by automating data interpretation and decreasing human variability [60]. By examining clinical characteristics, urine data, and electronic health records, AI-driven models may be able to predict the probability of a UTI far earlier than conventional culture-based techniques. Antimicrobial stewardship is strengthened and timely treatment decisions are made possible [61, 62].

Machine-learning algorithms have shown great sensitivity and specificity in predicting resistance patterns and identifying causative organisms in retrospective datasets, especially for common uropathogens like *Escherichia coli* [63, 64]. Additionally, many days before culture results are available, AI-assisted decision-support systems can recommend empirical antibiotic therapy, which may reduce inappropriate antibiotic exposure and the consequent emergence of resistance [65, 66]. AI integration with quick molecular and point-of-care (POCT) systems is another recent development that has reduced turnaround times in clinical microbiology [67]. Despite these encouraging advancements, issues including dataset bias, a lack of multicenter validation, regulatory concerns, and limitations integrating AI tools into current laboratory information systems (LIS) continue to hinder normal clinical adoption. Clinician acceptability and the need for prospective clinical research continue to be significant challenges. Therefore, to close the gap between technical innovation and clinical application, interdisciplinary collaboration, cost-effectiveness evaluations, and systematic validation are crucial.

CONCLUSION

The identification and treatment of urinary tract infections (UTIs) have been profoundly changed by developments in microbiological and molecular diagnostics. Although traditional urine culture is still the gold standard, its shortcomings in terms of sensitivity and turnaround time have prompted the use of quick diagnostic techniques. These include metagenomic sequencing, nucleic acid amplification methods, improved culture systems, and

automated urine analyzers. These developments make it possible to identify pathogens earlier and more precisely, detect fastidious or polymicrobial diseases more accurately, and start targeted antimicrobial therapy more quickly. Clinical decision-making and diagnostic accuracy have been further enhanced by the incorporation of new technologies such biosensors, point-of-care molecular tests, antimicrobial resistance gene identification, and artificial intelligence. By lowering the use of empirical antibiotics and enhancing patient outcomes, these developments collectively promote antimicrobial stewardship. The future of UTI diagnostics is expected to be driven toward quick, individualized, and data-driven healthcare solutions through ongoing technology progress and interdisciplinary collaboration, despite obstacles relating to cost, standardization, and clinical validation.

ABSTRACT

Parkinson's disease prevalence is projected to increase substantially over the next decade, largely driven by population aging.The primary objective was to evaluate whether an 8-week sequential intervention of Pilates followed by resistance training could improve balance and postural control in this group.This study enrolled 30 participants aged 55–65 years diagnosed with PD.Participants completed 4 weeks of Pilates exercises, then 4 weeks of resistance training.The primary outcomes of this study were balance and postural control, measured using the Fullerton Advanced Balance Scale, the Timed Up and Go test, and the Unified Parkinson's Disease Rating Scale.Normality of the dependent variables was assessed using the Shapiro-Wilk test, which indicated a normal distribution with $p > 0.05$. Statistical analysis was performed in SPSS version 24. Differences were considered significant at $p < 0.05$, and all results are reported with 95% confidence intervals. Paired t-test was adopted to find the statistical difference within the groups.The findings indicate that an 8-week program combining Pilates and resistance training leads to measurable improvements in balance and postural control for individuals with Parkinson's disease.

Keywords: Parkinson's disease, Fullerton advanced balance scale, Timed up and go test, Unified Parkinson's disease rating scale, Pilates exercise.

INTRODUCTION

Parkinson's disease is a degenerative condition affecting the central nervous system, characterized by a combination of motor impairments and non-motor manifestations. The hallmark motor features of Parkinson's disease consist of rigidity, bradykinesia, and tremor. As the disease advances, postural instability often develops and generally shows limited response to pharmacological treatment or deep brain stimulation[1]. Non-motor manifestations of Parkinson's disease can appear several years before motor symptoms emerge. Non-motor symptoms frequently appear in the early stages and may include anosmia, constipation, REM sleep behavior disorder, mood disturbances, and orthostatic hypotension. Postural instability is a hallmark motor feature of PD. It results from neurodegeneration and can appear at any disease stage, contributing to difficulties with daily activities, falls, and injury risk. Compared to age-matched healthy adults, individuals with PD exhibit greater balance deficits and a higher incidence of falls. Researchers have examined both non-modifiable and modifiable risk factors for postural instability in Parkinson's disease. Non-modifiable factors include age, genetic mutations, and race, while modifiable factors encompass environmental exposures and lifestyle variables[2].Balance impairments in PD are primarily attributed to factors including muscle weakness, axial rigidity, bradykinesia, freezing of gait, and deficits in sensorimotor integration and cognitive function. Epidemiological evidence indicates that PD occurs more frequently in men[3], a pattern that was also present in the current study sample for all cases and across every PD subtype[4,5].

Pilates is a mind-body exercise system that targets core stability, muscular strength, flexibility, posture, and breathing control. Movements are typically performed on a mat or using spring-based equipment. Joseph Pilates created this exercise method in 1926[6]. In the 2000s, healthcare professionals modified and adapted Pilates exercise for therapeutic use under the term 'clinical Pilates exercise' [7]. The method combines stretching and strengthening exercises designed to build both physical strength and flexibility, while also enhancing body awareness and control. The key principles of Pilates are: centering, concentration, control, precision, breath, flow [8]. The core principles of Pilates involve the co-activation of trunk stabilizer muscles. This promotes awareness of neutral spine alignment and strengthens the deep spinal musculature. Physiotherapists can progress Pilates exercises by gradually reducing external support and modifying movements to match individual patient needs. Training also emphasizes purposeful gait patterns and helps patients recognize and correct faulty walking mechanics to reduce ground impact and joint stress. Conradsson et al. (2015) evidence suggests that advanced balance training produces greater neural adaptations in people with PD compared to conventional therapy approaches[9]. Canning et al. (2014) prior work has shown that structured balance and strength programs can reduce fall risk in this Population[10]. A systematic review of eight studies also concluded that Pilates is an effective intervention for improving lower limb function, balance, and overall physical fitness in individuals with Parkinson's disease.[11].

Resistance training is recognized as an effective strategy to improve motor function, muscular strength, and endurance in PD [12-15]. Muscle weakness correlates with increased fall risk and postural disturbances in PD. Compensatory mechanisms play an important role in Parkinson's disease and increasing strength through resistance training may facilitate activation of muscle-groups associated with balance. Similar protocols have been applied in healthy older adults to enhance balance and functional capacity. Supporting this, Canning et al. reported that combined training focusing on balance, strength, and gait freezing can improve postural control in PD patients[16].
The present study applies these principles using sequential Pilates and resistance training to target balance and postural control deficits.

MATERIALS AND METHODS

For this study, participants with PD were recruited from the physiotherapy outpatient department at UCA College of Paramedical Sciences, Chennai, following referral by a neurologist. The study inclusion criteria are: Subjects aged 55-65 with Hoehn and yahr stage 2-3 Parkinson's disease [PD] and a minimum score of 26 on the mini-mental test

[MMT], Idiopathic Parkinson's disease [Diagnosed by Neurologist], patients who had never engaged in any regular exercise activities or received any other physical therapy, Stable pharmacological treatment who were diagnosed with Parkinson's disease [PD] within a year or more [17], Medication ON- state [1 hour after the last intake of antiparkinsonian medication], Postural instability [Fullerton advanced balance FAB scale ≤ 25 points], In the two years prior, there was a history of one or more falls or near falls. Exclusion criteria were: Individuals with severe mental and psychological disorders, significant musculoskeletal disorders, deformities of the lower extremities, other neurological diseases, changes in medication or dosage, during treatment, advanced age, and low MMT score were excluded, Hoehn- Yahr stage more than 4, If their mobility was impeded by any physical disabilities or other medical conditions, Previously diagnosed with dementia and stroke, Severe dyskinesia and/or motor fluctuations were experienced, Other diseases that could influence stance and gait performance.

The ethical committee of UCA College of Paramedical Sciences, College of Physiotherapy (vide IEC no. 001/01/2026/IEC/UCACOPT) approved the study on 4thJanuary, 2026.A blinded researcher selected participants for the study, around sixty participants who visited the OPD. They were analyzed based on the selection criteria, and informed consent was obtained from each patient before the study. Thirty participants were included in this study, and the rest were excluded as they did not fulfill the selection criteria. The materials used for the study were arm resting chair, stopwatch, mat, thera band and weight cuff. Subjects were pre- assessed by Fullerton advanced balance [FAB] scale, Timed up and go [TUG] test, Unified Parkinson's disease rating scale [UPDRS]. The study conducted for 8weeks. Participants were given the Pilates exercise for first 2 weeks [2 session per week]. Each session lasts for 45 minutes, consists of 5 minutes warm-up, followed by Pilates for 30 minutes and 10 minutes cool-down. Warm-up exercise included spine stretch, free exercise to all joints and breathing exercise. Main exercise done for first 2 weeks were: One leg stretch, hip twist, side kicking. Each exercise started with eight repetitions. The number of repetitions were increased depend on the patient's capabilities. Finally cool down exercises included spine stretch, the mermaid and breathing exercise. Exercise done for next 2 weeks: One leg kick, one leg circles, spine twist.

Resistance training started after 4 weeks [3 session per week] with same protocol given before weeks. Main exercise were: Squats, knee extension with weight cuffs, calf raises, toe raises and hip flexion with bands, hip flexion with weight cuffs, hip abduction, ischiocrural muscles with bands. Exercise are performed three sets of 15-20 repetitions to volitional fatigue of each exercise. Resistance is increased once participants could complete more than 20 consecutive repetitions of an exercise. Participants were given rest for 2 minutes between each exercise sets. The primary outcome for this study are Fullerton advance balance [FAB] scale, Timed up and go [TUG] test, Unified Parkinson's disease rating scale [UPDRS]. The FAB scale is a 10-item clinical balance scale [18] with a 5-point ordinal scale [0-4] for each item and a maximal score of 40 points [higher values indicate better performance]. For this tool, an interrater reliability of 0.94-0.97 and a test-retest reliability coefficient of 0.96 also calculated [19-21]. The timed up and go test [TUG],which is reliable and valid method [22]. The patient is seated comfortably in a firm chair with arms and back resting against the chair. Timing with a stopwatch begins when the patient is instructed to "go" 3meters and ends when the patient return to the start position seated in the chair. The UPDRS is a rating tool to follow the longitudinal course of Parkinson's disease [23]. It is made up of the: Mentation, behaviour and mood, activities of daily living, motor sections. A total of 199 points possible 199 represents the worst [total disability], 0 no disability. All the parameters were assessed using statistical package for social science (SPSS) version 24, with a significance level of p value less than 0.05 and a 95% confidence interval set for all analysis. The Shapiro Wilk test was used to determine the normality of the data. In this study, Shapiro Wilk test showed that the data was normally distributed on the dependent values at $P > 0.05$. Hence parametric test was adopted. Paired t-test was adopted to find the statistical difference within the groups.

RESULTS

On comparing mean values of Fullerton Advanced Balance Scale Score between Pre-test 22.30 ± 1.62 and Post-test 26.90 ± 1.64 within Group, it shows there is a highly significant difference in between Pre-test and Post-test mean

values with t value shows -15.85 at P ≤ 0.05. The Post-test values have shown improvement when compared with the pre-test. Hence, the null hypothesis is rejected. On comparing mean values of Timed Up and Go Test Score between Pre-test 15.60 ± 1.90 and Post-test 13.00 ± 1.83 within Group, it shows there is a highly significant difference in between Pre-test and Post-test mean values with t value shows 12.57 at P ≤ 0.05. The Post-test values have shown improvement when compared with the pre-test. Hence, the null hypothesis is rejected. On comparing mean values of Unified Parkinson Disease Rating Scale Score between Pre-test 96.76 ± 13.25 and Post-test 92.20 ± 13.83 within Group, it shows there is a highly significant difference in between Pre-test and Post-test mean values with t value shows 12.32 at P ≤ 0.05. The Post-test values have shown improvement when compared with the pre-test. Hence, the null hypothesis is rejected.

DISCUSSION

The study found that an 8-week sequential program of Pilates exercise followed by resistance training significantly improved balance, functional mobility, and disease severity in patients with Parkinson's disease. Post-intervention, UPDRS scores decreased by 4.37 points, TUG time reduced by 2.67 seconds, and FAB scores increased by 4.40 points, all with $p < 0.001$. These improvements are clinically meaningful. A change of >2.5 seconds in TUG and >4 points in FAB is considered the minimal detectable change for fall risk reduction in PD. The risk of falls in these patients is also strongly correlated with postural control disorders [24]. By improving these patient's functional capacity, various training interventions, such as aerobic exercises, hydrotherapy, balance, and gait training, result in significant therapeutic benefits [25,26]. Kibar et al. (2015) discovered that while there was no significant correlation between core muscle endurance and balance, eight weeks of Pilates exercise had positive effects on older adults static and dynamic balance and core muscle endurance [27]. Pilates likely contributed to enhanced trunk stability, core control, and body awareness, while resistance training improved lower limb strength and power, both essential for postural control. In contrast to light walking, these exercises primarily enhance the musculoskeletal elements that contribute to mobility, neuromuscular coordination, and the application of balancing motor strategies, which are followed by facilitating motor learning [28-32]. The sequential approach may allow neuromuscular adaptation before progressing to higher loads. Our findings are consistent with previous studies showing that combined exercise approaches are more effective than single-mode training for balance in PD. Johansson et al. stated that balance is result of mind-body interactions as well as physical balance [33]. The program is low-cost, requires minimal equipment, and can be delivered at the primary healthcare level, supporting SDG 3.4 for reducing disability burden. Limitations include the lack of a control group and the inability to separate the effects of Pilates vs resistance training due to the sequential design. Carryover effects cannot be excluded. Future randomized controlled trials with crossover designs are needed to confirm these results.

CONCLUSION

An 8-week sequential program of Pilates exercise followed by resistance training significantly improved balance, functional mobility, and disease severity in patients with Parkinson's disease. The intervention led to clinically meaningful reductions in UPDRS and TUG scores, and increased FAB scores, indicating reduced fall risk. This low-cost, feasible approach may be suitable for community-based rehabilitation in primary health care settings.

ACKNOWLEDGEMENT

The author expresses his gratitude to all the participants as well as the U.C.A. College of Paramedical Sciences, College of Physiotherapy administration for allowing him to research on their campus.

Conflict of Interest
The Authors declare no conflict of interest. There is no Grant or Fund Support for this study.

ABSTRACT

Glaucoma is one of the chronic progressive disorders of the eye characterized by visual loss, mainly occurring due to a rise in intra-ocular pressure. It is one of the major causes of blindness. The incidence and prevalence in India estimated that there are approximately 11.2 million persons aged 40 years and older with glaucoma in India. The estimated number with primary angle closure glaucoma is 2.54 million. Primary open-angle glaucoma is estimated to affect 6.48 million persons.

Keywords: Glaucoma, Homoeopathy.

INTRODUCTION

Glaucoma is one of the chronic progressive disorders of the eye symptomatically visual loss, mainly occurring due to a rise in intraocular pressure. The most important factor which causes rise in intraocular pressure is obstruction of the drainage of the aqueous humor through the angle of the anterior chamber and at the pupil.The intraocular pressure (IOP) refers to the pressure exerted by intraocular fluids on the coats of the eyeball. The normal IOP varies between 10 and 21 mm of Hg.

Open-angle glaucoma

Open-angle glaucoma is the most common form of the disease. The drainage angle formed by the cornea and iris remains open, but the trabecular meshwork is partially blocked. This causes pressure in the eye to increase. This pressure damages the optic nerve. It happens so slowly that it may loses vision before aware of a problem.

Angle-closure glaucoma-Angle-closure glaucoma, also called closed-angle glaucoma occurs when the iris bulges forward to narrow or block the drainage angle formed by the cornea and iris. As a result of it, fluid can't circulate through the eye, and pressure increases. Some people have narrow drainage angles, are at high increased risk of angle-closure glaucoma.

Normal tension glaucoma-In normal-tension glaucoma, the optic nerve becomes damaged even though eye pressure is within the normal range.

Glaucoma in children-It's possible for infants and children to have glaucoma. It may be present from birth or developed in the first few years of life. The optic nerve damage may be caused by drainage blockages or an underlying medical condition.

Pigmentary glaucoma-In pigmentary glaucoma, pigment granules from the iris build up in the drainage channels, slowing or blocking fluid exiting the eye.

Case Summary

A 50 year/male no K/C/O any major illness come with the complaint of difficulty in seeing the object especially the peripheral vision ,headache in the frontal region since 2 weeks along with watery discharge & burning in both eyes.Twitching of eyelids since 2 days,letters appear red. There is eedema of eyelids and Pain in orbital bone for the complaints started patient Irritability increased .

Family Details

Father-Hypertension since 20 years on regular treatment.

Past History

Dengue fever at the age of 25 years, recovered with the Allopathic Management.

Physical General

Appetite: 2 times/day,Hunger Tolerable.
Thirst: 3 liter/day ,short quantity long interval.
Urine: 3 times/day ,1 times/night.
Stool: 2times/day,satisfactory.
Sleep: 6-7 hours/day/refreshing.

Habits/Addiction

Eating of Tobacco for 10 years(2 packets/day)

Diagnostic With Consideration

Ophthalmic examination-

Significance of Test

Glaucoma is examined through modern science to measure Intra-Ocular pressure in various categories like Tonometry Examination, Application of Tonometry through Gonioscopic to observe the thickness of cornea via Perimetry to evaluate the visual field defect via projection Perimetry and to know the status of retina ,macula, fovea ,opticdisk, retinal nerve fibre layer through OCT(Optical Coherence Tonometry) and easy process to examine IOP is NCT (Non control Tonometry) throughout lifetime.

Totality Of Symptoms

1-Difficulty in seeing an object.
2-Headache.

3-Watery Discharges,
4-Burning in both eyes.
5-Twitching in both eyes.
6-Odema in eyelids.
7-Pain in orbital bone.
8- Ameliorated by washing
9-Irritability during complaints.
10-Tobacco Addiction.

Repertorial Result
PHOS- 38/11, SULPH:35/10, ARS.ALB 33/1O, BELLA-31/09,NAT-M 30/10, SPIG 30/10.

Case Analysis
After a complete analysis and evaluation of symptoms,Totality was constructed based on the difficulty in seeing or an object, Headache, Watery discharges, Burning and Twitching,edema, pain in the orbital bone, complaints better by washing, Irritability during complain, and Tobacco addiction. According to Hahnemann's classification of diseases it comes under local surgical diseases, which comes under dynamic diseases given in aphorism 192,all the changes and symptoms are collected to form the totality of symptoms. After doing Repertorisation from the complete repertory Phosphorous was finally selected as a similimum.Based upon on age ,susceptibility and pathology 200 potency was given and frequent repetition given till the objective and subjective symptoms were relieved.

Treatment Approach
While going through the case after a detailed examination, physical particular qualified characteristics are prominent in the case which helps in choosing complete and reference to Materia Medica, Phosphorous covers the qualified physical particularssymptoms along with the objective symptom hence prescribed the medicine.

RESULT

DISCUSSION

This study concerns with the community through long -lasting medicine from modern medical science in some categories at are very high rate. So effectively of Homoeopathic medicine through easy to administer and very low rate ,so anybody can afford and prevent their vision.

CONCLUSION

The description and discussion regarding this study are going towards the prevalence ratio of the vision in the community. Different medicines are liable control IOP, to prevent retinal blindness, to maintain the optical status and functional condition of Glaucomatic structure, prevention of complications after Glaucoma diagnosis.

ABSTRACT

Organ transplantation law in India has evolved significantly with the enactment of the Transplantation of Human Organs Act, 1994 (THOA), later amended as the Transplantation of Human Organs and Tissues Act, 1994, with the objective of regulating organ removal, storage, and transplantation while curbing commercial dealings in human organs. Despite this progressive statutory framework and the establishment of institutional mechanisms such as the National Organ and Tissue Transplant Organization (NOTTO), the practical implementation of organ transplantation laws in India continues to face serious structural, ethical, and regulatory challenges. This paper critically examines the problems and future prospects of organ transplantation laws in India, with particular emphasis on the gray areas that undermine their effectiveness. The study identifies ambiguities relating to brain-death certification, consent procedures, living donor regulation, and the functioning of Authorization Committees. It highlights the persistent gap between legal intent and medical practice, especially in cases involving unrelated donors, cross-border transplant tourism, and allegations of coercion or financial inducement. Further, issues of infrastructural inequality, lack of awareness, regional disparities in cadaveric donation, and inadequate monitoring mechanisms complicate the enforcement of the statutory scheme. Ethical tensions between autonomy, altruism, and prevention of commercialization remain inadequately resolved within the present legal framework. The paper also explores emerging concerns such as data transparency, digital organ allocation systems, accountability of private hospitals, and the need for harmonization with international standards. While the law aspires to balance the right to health and human dignity with safeguards against exploitation, its gray areas often create interpretational inconsistencies and administrative discretion that may lead to arbitrariness. By adopting a doctrinal and policy-oriented approach, this study argues for clearer statutory guidelines, stronger oversight mechanisms, enhanced public education, and ethical standardization to strengthen the transplantation regime. It concludes that although India possesses a comprehensive legislative structure, meaningful

reform and robust implementation are essential to transform organ transplantation from a legally regulated activity into an equitable and ethically grounded public health system.

Keywords: Organ Transplantation Law, Transplantation of Human Organs and Tissues Act, 1994, Brain Death Certification, Living and Cadaveric Donation, Authorization Committees

INTRODUCTION

In the current scenario, one of the crucial aspects in the medical field is organ transplantation. The reason behind the significance of the issue is rising nowadays, as it has become one of the vital elixirs of life for any human being. Under the current medical innovative regime, organ transplantation entails an individual willingly donating an organ or tissue to help save a life from organ failure [1]. It is a key life-supporting measure that has revolutionised modern healthcare, reviving hope for those battling late-stage organ impairment. India's demographic scale and growing healthcare capabilities have catalysed an increased reliance on organ transplantation since the 1970s, defined by the initiation of kidney transplantation in India. The development of organ transplant procedures substantially improved the health outcomes of individuals with organ dysfunction, mitigating the scarcity challenge stemming from the chronic shortfall in viable organ supply. Challenges, including limited posthumous organ donors and identifying a medically viable match, have aggravated the organ scarcity in India.

The imbalance between organ availability and transplant demand has fuelled unethical practices, such as organ trafficking and illicit organ trade, which transgress legal standards [2]. The consequences of such practices are imposed upon socioeconomically disadvantaged groups, constituting a breach of the Right to Life enshrined in Article 21 of the Indian Constitution [3] [4]. In response to the urgency for a systematic framework in organ transplantation in India, the Indian Parliament enacted the Transplantation of Human Organs Act in 1994. It is responsible for monitoring and regulating organ retrieval, preservation, and transplantation for medical services while enforcing stringent anti-trafficking safeguards. The Transplantation of Human Organs and Tissues Act, 1994 (here, referred to as "THOTA") has been uniformly implemented across all states, excluding Andhra Pradesh, and Jammu & Kashmir, which have similar statutory frameworks [5]. Several amendments have been introduced to refine this legislation, with the most recent being the Transplantation of Human Organs and Tissues Rules in 2014, notified with effect from March 27, 2014.Despite the current organ transplant laws in India, the scenario remains dire. There has been a lack of a significant rise in the number of cadaveric donors or curbing the commercialization of organs. Brain death continues to be overlooked and inadequately addressed. Various other regulatory complexities hinder organ transplantation in India which needs to be resolved. Consequently, the legal scenario needs to be reassessed, requiring the formulation of new laws that align with the international conventions and principles of the Indian Constitution.

Features of Transplantation of Human Organs and Tissues Act, 1994

The 20th century marked the greatest medical development in India, including the introduction of law on the transplantation of organs. The introduction of mechanical ventilation into the treatment process of patients in a brain-dead condition, as well as the further development of immunosuppressive therapy, has transformed the aspects of organ donation and transplantation significantly [6].The practice of organ transplantation has become a life-saving technique and a reflection of human kindness, with people voluntarily willing to donate their organs to save the lives of others. An organ transplant is a life-saving surgical procedure involving a medically healthy donor to transfer his/her organs or tissues to a recipient with organ failure. In addressing various serious illnesses, such as liver diseases, kidney failure, or other last-stage organ failure, organ transplantation is seen as an effective and innovative survival alternative [7]. In India, the law relating to organ transplantation is governed by the Transplantation of Human Organs and Tissues Act, 1994, followed by the formulation of the Transplantation of Human Organs and Tissues Rules, 2014 for the enforcement of the Act. The Act lays down provisions regarding the removal, protection,

and donation of human organs and tissues for medical use and the prohibition of organ commercialisation. Section 2(h) of the Act defines a human organ as any part of a human body consisting of a structured arrangement of tissues which, if wholly, removed, cannot be replicated by the body. Section 2(p) refers to transplantation as the grafting of any human organ from any living person or deceased person to some other living person for therapeutic purposes [8]. The Act permits the practice of organ transplant to be conducted by hospitals or registered centres licensed by a competent authority. According to the Act, the donor and the receiver should be directly related to each other, and the organ transplantation can only be made when the donor meets the informed consent. These provisions ensure that organ transplantation is voluntary and ensure that all the parties are fully aware of the consequences involved [9]. The Act, further, governs the setting up of government-approved organ transplantation centres which are delegated with carrying out organ transplants being done in compliance with set rules of organ matching that exist between the donor and the recipient or donor and recipients of organs as well as protocols governing organ sourcing and transplantation. The Transplantation of Human Organs (Amendment) Bill, 2011 established the National Apex Committee for Regulation of Transplantation (NACROT) to implement measures for overseeing living donor transplantation. The Act also mandates the Central Government to incorporate a national registry of the donors and recipients of human organs and tissues [10].

Classifications of Human Organ Transplantation

Organ donation can be classified into two categories: Living Organ Donations and Deceased Organ Donations. Living Organ Donation is when you procure an organ from a healthy living donor and graft it into the body of a recipient suffering from last-stage organ failure. This procedure is typically undertaken when kidney or liver failure occurs, as the liver has the capacity to regenerate, and a single kidney is adequate to maintain body functions. Living donors may be identified as either a near relative or a distant relative. A near relative means a spouse, son, daughter, father, mother, brother, sister, grandfather, grandmother, grandson or granddaughter. A distant relative can be any person except a near relative, who first requires authorisation from the State Authorisation Committee to be able to transplant organs. If the hospital refuses to handle such cases, the patient may serve a legal notice on the hospital for contravening the Transplantation Act [11].

Deceased Organ donation is simply the act of donating or transplanting organs after the death of the donor. By death, it means that the person has been declared brain-stem dead by a registered medical practitioner, by a personal examination of such body. A person can be considered brain-stem dead if there is a state of permanent unconsciousness, loss of brain-stem responses, and cessation of respiratory function [12]. A deceased organ donation shall only be permitted after brain-stem death has been certified, and where the brain-stem death occurs of any individual less than eighteen years of age, permission from any of the parents of the deceased person is mandatory for the removal of the tissue or organ from the body of the deceased person [13].

Medical Procedures for Organ Transplantation

Any living person who is willing to give his/her tissue or organ to any person with tissue or organ failure can be termed as a living donor. It may include parents, siblings (related donors), and also spouse donors. In case of related donors, authentic documents verifying the relationship must be submitted in accordance with the Act. Additionally, where either the living donor or the recipient, being a near relative, holds a foreign nationality, no human organ or tissue shall be transplanted without prior approval from the Authorisation Committee. And where the donor, being an Indian national, agrees to transplant his/her tissue or organ to a recipient holding a foreign nationality, such removal or donation shall not be approved by the Authorisation Committee [15].

Spouse donor*:* In case where the donor and the recipient are a married couple, documentary evidence such as a marriage certificate, marriage photographs, important family information like the number of children and the age of children, a family photograph portraying the entire family, birth certificates of the children, is mandatory. Other than near relatives: It is a debated aspect of organ donation due to the concerns surrounding illegal, coercive, and profit-

driven organ transplants. If there is no biological relation between the donor and the recipient, approval from the authorization committee is required.

Swap donor: The donation of tissues or organs by donors who are family members but have different blood types is referred to as swap donation. Provisions for swap donor transplantation are included in the Transplantation of Human Organs and Tissues Act, 1994, following the most recent amendment in 2011. Section 9 sub-section 3A provides for swapping of 'near-relative" donors of biologically incompatible recipients, subject to prior consent of the Authorisation Committee [16].

Donor or recipient belonging to different states: In situations where the donor, recipient, and transplantation center are situated across different states, then obtaining approval or a 'no objection certificate' from the respective State Government is mandatory.

Foreign donors: The Act places stringent regulations on foreign donors. When either the donor or recipient is a foreign national, the removal or transplantation of human tissues or organs shall require the prior approval of the Authorisation Committee. An Indian living donor shall not donate organs to a foreign recipient unless the donor is a near relative of the recipient. Additionally, a senior official of the respective country's embassy in India is responsible for certifying the donor-recipient relationship.

Cadaver donors: Also known as deceased donor transplant, it involves the donation of tissues or organs by a deceased individual. Organs, including bones, skin, kidneys, liver can be transplanted from cadaver donors

Current Legal Frameworks and Legal Mechanisms

The Transplantation of Human Organs Act, enacted in 1994 and came in February 1995, was amended in 2011 and 2014, which aimed to restrict the practice of organ trafficking and encourage cadaver donations. Some of the key provisions highlighted in the Act include: Section 13-15: Appointment of appropriate authorities and tissue banks
Medical institutions conducting organ transplants must be duly registered with the appropriate authorities to be involved in:

- The retrieval, storage, and donation of any human organ;
- For Tissue banks to be involved in the process of retrieval, examination, testing, preservation, and dissemination of tissues.

Authorisation committees

The Act calls for the establishment of Authorisation Committees by the Central and State Governments to evaluate applications for transplantation between unrelated donors and recipients. Under Rule 7 of the Transplantation of Human Organs and Tissues Rules, 2014, these committees aim to prevent coercion and financial exploitation in verifying the relationship claimed by the donor and the recipient [17].
Brain-stem death and cadaveric donors: The Act allows for the removal of tissues or organs from the bodies of patients in the event of brain-stem death, provided that such death has been certified. Every organ donation procedure shall include the following steps before the transplant is carried out [18].
A board consisting of four medical practitioners, two of whom belong to a board appointed by the government, must confirm and declare brain-stem death. This evaluation has to be conducted twice, with a six-hour interval between the tests. The board shall comprise of:

- A registered medical practitioner working under the hospital where the admission of brain stem death patient took place.
- A registered medical practitioner who has been chosen among a panel of doctors under the approval of the Authorisation Authority.

- A neuro-surgeon (in case where a neuro-surgeon is not available to conduct the tests, the panel may include any Physician or Anaesthetist who has been chosen by the Medical Administrator in-charge among a list of names approved by the Authorisation Authority [19].

This transplantation process has to been strictly complied with. The certifying clinicians must not have any personal interest in the transplantation of cadaver organs. The certification must be in accordance with the provisions of the Transplantation of Human Organs and Tissues Act, 1996. The medical superintendent in charge of the hospital should finally cross-check and sign the form. The organs can only be allowed for retrieval, removal, or donation after the completion of these due procedures.

Challenges Ahead

In the Indian context, the demand for donor organs greatly outweigh their availability. Over the last decade, the rate of cadaveric organ donation in India has remained persistently under one donor per million population. While there is a significant increase in donors from 6,916 in 2014 to 16,041 in 2022, around 85% of all donations are made by living donors. Despite an annual need of 200,000 kidney transplants, around 10,000 transplants are carried out each year., aggravating the shortage. A 2022 report by NOTTO states that an estimated 15,561 organ transplants were performed in India, with only 2,765 originating from deceased donors. Living donors make up 82% of all organ donations in India. This represents the necessity to raise deceased organ rates for donors, including kidneys, liver, and heart, which remains notably low [20]. The number of deceased donors varies across the states. As per NOTTO, Telangana reported the highest number of deceased donors in 2022. This is associated with advancements in healthcare services, especially in the context of COVID-19. The increased access to ICUs ventilators, and ECMO machines has optimized emergency management, resulting in more successful donations. Overall, despite the rise in organ donation figures, India continues to face an acute shortage of organs, causing serious difficulties for patients in need of transplants. The challenges are as follows,

- **Organ trafficking**: Based on estimates reported by Global Financial Integrity, an estimated 10% of heart, liver, and lung transplants are sourced through illegal means. As reported by the Human Rights Organisation, nearly 44,000 children go missing in India yearly, with most of the cases constituting organ trafficking. Despite rigorous legal provisions, the illegal organ trafficking remains prevalent, particularly in the marginalized communities.
- **Consent for organ transplant**: Organ donation requires the informed consent of the donor or his family, in case of death. However, cases exist in which the legal validity of the consent has been disputed, particularly relevant to deceased donors, and the family members have conflicting opinions about organ donation. Additionally, while the law encourages voluntary donation, concerns exist as to whether individuals are truly providing informed consent or coerced in any manner, especially when donors are economically disadvantaged. The legal status of living donors and potential exploitation continues to occupy a gray area in the eyes of law.
- **Lack of transparency**: It is often presumed that organ distribution is based on high-level connections, rather than patient's medical necessity. Although authorities are mandated to follow a transparent procedure, the law fails to ensure accountability for authorities who default.
- **Low public awareness and education**: There is a limited awareness about the significance of organ transplantation in India. The erroneous perception that organ donation is unnatural, coupled with religious prohibitions, results in shortage of organs [21].

CONCLUSION AND SUGGESTIONS

The laws regulating organ transplantation in India, THOTA, have encountered numerous implementation challenges, including organ scarcity, illegal organ trade, ethical considerations, and societal apathy. A major section of our Indian society is triggered by organ trafficking, and the primary drivers motivating unrelated organ donors pertain to poverty and debt. To address these challenges, the researcher has suggested a few reforms as follows:

Strengthened enforcements: The government must work towards improving the implementation of laws relating to human organ trafficking. For any kind of involvement in illegal organ trade, individuals shall be subject to stringent penalties, and better surveillance and monitoring shall be introduced to deter criminal ties and combat such legal challenges. Concern towards the organ donor while encouraging more organ donation: The health of the organ and tissue donor must be of paramount concern, especially during the post donation health complexities. In the current scenario, there is a pressing need to encourage more donation to combat the scarcity. Awareness benefits showcasing the significance of posthumous organ donation, coupled with more efficient consent processes should be established.

Education on healthcare: Strengthened healthcare and training programs for healthcare experts shall be introduced to encourage understanding the procedure of organ donation, the legal and ethical considerations, and counselling programs for organ donors.

Transparency in transplantation procedures: Transparently ensuring the allocation of organs and promoting equitable availability to transplantation can prevent the practice of favouritism in organ matching. A more reasonable and transparent practice would increase credibility in the system and reduce unlawful practices.

ACKNOWLEDGEMENT

The author declares that this research has been carried out independently. No external funding, institutional sponsorship, or financial assistance was received for the completion of this study. The work is purely academic in nature and is based on the analysis of statutory provisions, judicial decisions, scholarly writings, and publicly available sources.
The author further states that there are no conflicts of interest associated with this research.

ABSTRACT

In this paper Fuzzy logic of stress is the action taken to adjust any change inphysical, mental and emotional status in response. Nowadays we stress ourselves in connection with the surrounding events in which we face many problems. The stress in the workplace where we spend most of the time is the most harmful physical and emotional responses that can raise the pressure levels in the body. Heavy workload within a short spell of time can lead to stress. Adverse mental and physical changes occur in a person who is unable to handle his stress. In this paper we use Hamming distance and proposed distance measure to analysis the stress.

Keywords: Stress, Fuzzy Logic, BP, hamming distance, proposed distance measure.

INTRODUCTION

Fuzzy logic has been applied to various fields where the value of truth many range between completely true and the completely false i.e., to handle the concept of partial truth. The most common and significant health disease nowadays is stress, which affects the human physically and mentally bad. The excess chronic physical and mental stress has become threat for the individual which leads to suicides. Stress is an emerging challenge to the life and health of human, though it has become apart of our life [1], [2].It is significant importance to detect stress before it becomes a high problem. Stress simulation depends upon two mechanisms; Alarm reaction and the adaptation. If an individual undergoes a peculiar or unpredicted threat in the workplace they respond to increased muscular activity. Secondly the individual becomes anxious if things do not work the way they have adapted to the workplace. Stress

has a background with two forms. i.e., physical and mental. The disturbance in bodily environment or mental working strategy of the individual maybe due to family background [3], [4]. It is a complicated process to understand human stress level. Response to stress differs from individual to individual. The experience and the behavioral difference in overcoming the problems/situations, individual characteristics, gender, age, physical and mental conditions itself will give variations in individuals stress level. Based on that the stress response system will react different from each individual. Hence the psychological response to stress of human beings vary. Mostly it is difficult to describe the stress level. The person feels that their body is under stress but it is difficult to judge their stress level whether high or low. Sometimes physical responses of human have different value from time to time [8].

METHODOLOGY

The samples were collected from 50 individuals (faculty members) working in Bharath College of Science and Management, Thanjavur, Tamil Nadu, India. In that ratio of female and male 30:20 depending on the variance of gender, age, blood pressure for analyzing stress level started from the age of 25 to 55 years.
Blood Pressure levels:

Normal: 80/120 Low: 60/90 High: 100/140

Fuzzy Logic Rules
If age below 35 and BP is high then stress level high
If age above 35 and BP is high then stress level Medium.

Distance Measures between Fuzzy sets
For two fuzzy sets Mand N in the same universe, the Hamming distance is an ordinal measure of dissimilarity. The Hamming distance (HD) is defined as

$$|HD(M,N)| = |\sum_{i=1}^{n} |\mu_M(x_i) - \mu_N(x_i)||$$

where n is the number of points that define the fuzzy sets M and N, $\mu_M(x_i)$ the membership of point x_i in M and $\mu_N(x_i)$ is the membership of point $x_i$in N. The Hamming distance is smaller for fuzzy sets that are more alike than those that are less similar.

Proposed Distance Measure
The proposed distance measure D(M, N) is defined as:

$$|D(M,N)| = |\frac{1}{4}(\sum_{i=1}^{n} |\mu_M(x_i) - \mu_N(x_i)| + \sum_{i,k=1(i\neq k)}^{n} (2(2|i-k|-1)\mu_M(x_i)\mu_P(x_k)))|$$

Where M is the actual fuzzy classification n the number of classes that define M and P, $\mu_M(xi)$ is the membership of point x_i in M and $\mu_P(x_k)$is the membership of point $x_k$in P.

RESULT

Table 1 shows the data collected from various Professors. Fuzzy logic is used to determine risk of stress. This design consists of two inputs and one output. The input consists of age, blood pressure while the output is the risk of stress.

CONCLUSION

In this concluding chapter we summarized the ideas that how to develop the basic behavior of our life and the research methodologies using hamming distances and proposed distance measure. From this research we got some

different types of result among the different types of age groups. The age between 25 to 35 having too much of stress and the BP level is high and also they are suffered a lot in all shots like nature of work, insecurity of job, inferiority complex, lack of concentrate, and they do not know how to handle the problems in critical situations meanwhile at the age of 35 and above had the same level of BP but they are control their BP level and lead their life in peaceful manner, experience in nature of work, doing some kinds of exercises and made some changes of their food habits, these are main concepts I got at the time of research. Infuture we planned to give some innovative solutions to reduce their stress and BP level for the age group 25-35.

ABSTRACT

Haemovigilance is a comprehensive surveillance system that enhances transfusion safety by monitoring, reporting, analyzing, and preventing transfusion-related adverse events. It supports patient safety, reduces preventable errors, and promotes evidence-based transfusion practices. This review highlights the objectives, components, and significance of haemovigilance, including national and international programs and the Haemovigilance Programme of India (HvPI). It also addresses challenges such as underreporting, limited infrastructure, and inadequate awareness, particularly in resource-constrained settings. Emerging technologies, including electronic reporting systems, data analytics, and artificial intelligence, offer opportunities to strengthen haemovigilance and improve patient outcomes through safer and more effective transfusion practices.

Keywords; Haemovigilance, transfusion safety**,** adverse transfusion reactions, blood transfusion, patient safety, transfusion medicine.

INTRODUCTION

The term haemovigilance (French: hémovigilance) was originally used in France. Its roots are the Latin word vigilans, which means "watchful" or "vigilant," and the Greek word haem, which means "blood." A thorough monitoring

system called hemovigilance is intended to guarantee security during the transfusion procedure.[1]It is defined by the WHO, International Haemovigilance Network, and ISBT with the goal of identifying, reporting, analyzing, and preventing adverse events associated to transfusions. Haemovigilance is essential to improving transfusion processes globally because it improves patient safety, quality assurance, and risk management.[2]The significance of reporting systems in enhancing patient safety and healthcare quality was emphasized in the World Health Organization's 2005 study, Adverse Event Reporting and Learning Systems: From Information to Action. Adverse events are unanticipated blood transfusion-related incidents in transfusion medicine, whereas adverse reactions are detrimental transfusion-related patient reactions. Good reporting improves safety and helps stop recurrence.[3]Only 13% of low-income nations had national haemovigilance systems in place, compared to 30% of middle-income countries and 78% of high-income countries, according to the WHO Global Database on Blood Safety Summary (haemovigilance statistics for 2011–2012 and 2012–2013). These results show notable differences in how hemovigilance systems are implemented in various economic contexts. Therefore, in order to make evidence-based improvements in the safety and quality of blood transfusion practices worldwide, it is imperative that national hemovigilance programs be established and strengthened. [4-5].This will ultimately enable better standards, regulations, and patient care.[6]Because it facilitates the execution of preventative and corrective measures while encouraging the ongoing development of the safety and quality of blood, blood components, and transfusion procedures, hemovigilance is an essential part of quality management in blood transfusion services. In the PDCA (Plan-Do-Check-Act) cycle, it also serves as the "check" phase, supporting continuous process improvement. [7]Over the past few decades, many countries have established haemovigilance systems to improve transfusion safety. Blood donation rates vary widely, averaging 39.2 per 1,000 population in developed countries, 12.6 in developing countries, and only 4.0 in low-income countries, highlighting disparities in access to safe blood.[8,9]

History of Blood Transfusion and Hemovigilance need

In the 19th century, Henri Leacock and James Blundell pioneered human-to-human blood transfusion to manage acute blood loss, although it was considered a last-resort treatment due to significant risks. The 20th century brought major advances, including the discovery of the ABO blood group system, improved cross-matching methods, and anticoagulants, making transfusion safer and widely accepted. [10,11,12]As a result, France started pioneering work in hemovigilance in 1991 when blood transfusion committees established monitoring systems. This eventually resulted in the creation of a nationwide hemovigilance network in 1994. [13]In order to improve blood safety, the European Council passed a resolution in 1995 after France implemented the first hemovigilance system in 1994. In order to foster international cooperation, information exchange, and education, the European Haemovigilance Network (EHN) was founded in 1997 and subsequently changed its name to the International Haemovigilance Network (IHN). [14-15]The International Haemovigilance Network (IHN) is connected to several developed nations' haemovigilance initiatives, albeit national administration varies. TRIP (Netherlands), TTISS (Canada), and SHOT (UK) are notable systems. Although these initiatives have increased transfusion safety, many Asian nations still lack comprehensive hemovigilance systems and data. [16-17]Only 58% of developed nations have transfusion committees in more than half of their institutions. These results show that blood use and transfusion procedure monitoring continue to be important worldwide health issues. Additionally, there are still significant gaps in the surveillance, reporting, and investigation of transfusion-related adverse events, reactions, and near-miss situations, as well as in the systems in charge of monitoring transfusion policies and procedures. [18]

Components of Hemovigilance

An ideal system includes the whole transfusion chain, from donation to patient follow-up, although some merely track transfusion reactions. It guarantees donor-recipient traceability, monitors adverse events, infections, mistakes, and near misses, and supports patient safety, compliance, and remedial measures. [19]

Hemovigilance for Recipient

Recipients' unfavorable transfusion reactions are graded using a globally recognized standard. The severity classification, which ranges from minor symptoms to potentially fatal complications, aids in assessing the clinical

significance of the reaction. Imputability, or the possibility that a transfused blood component caused the adverse reaction, is assessed in addition to severity assessment. To ascertain whether the transfused blood component was certainly, probably, potentially, or unlikely to be the cause of the observed reaction, imputability assessment is crucial. The International Society of Blood Transfusion (ISBT) has created uniform standards for transfusion reaction severity and imputability. Additionally, the International Haemovigilance Network (IHN) and ISBT joint working group produced globally recognized standards for adverse transfusion events in recipients. These standardized standards make it easier to report consistently, enhance communication between hemovigilance systems, and allow for the meaningful comparison and exchange of hemovigilance data between various nations and healthcare systems. [20-21]

Hemovigilance for Donor

In order to guarantee the general safety and quality of the transfusion procedure, blood donor haemovigilance is equally crucial, especially when it comes to adverse events or responses that may occur during whole blood or component donation. Because their etiology is different from that of adverse responses seen in transfusion recipients, unpleasant reactions that occur in donors are typically referred to as donor complications. A joint working group of the European Haemovigilance Network (EHN) and the International Society of Blood Transfusion (ISBT) has developed a classification system and standardized terminology for donor problems in order to standardized reporting and surveillance. These donor complications are broadly categorized into local reactions related to needle insertion, such as vessel injuries, nerve injuries, and other localized events, as well as general reactions, including immediate and delayed vasovagal reactions. Additional categories include other significant complications associated with blood donation. Similar to recipient adverse reactions, the severity and imputability of donor complications are assessed using an internationally accepted grading scale, which enables consistent reporting, analysis, and comparison of donor haemovigilance data across different haemovigilance systems worldwide. [20&22]

Types of Transfusion Reactions

Acute hemolytic transfusion reactions (AHTRs)

The fast destruction of transfused red blood cells, which causes clinical symptoms and hemolysis in the lab, is the hallmark of acute hemolytic transfusion reactions (AHTRs). Usually, symptoms appear minutes after the transfusion is started. Hemoglobinemia, hemoglobinuria, reduced serum haptoglobin, unconjugated hyperbilirubinemia, increased lactate dehydrogenase and serum glutamic-oxaloacetic transaminase levels, and a reduction in hemoglobin concentration are common laboratory results. Rarely, hemolysis of the recipient's red blood cells may also occur from transfusions of ABO-incompatible plasma, such as ABO-mismatched platelet transfusions, especially if the donor plasma has high titers of ABO antibodies. roughly 1 in 76,000 transfusion units have been reported to experience AHTRs, and roughly 1 in 1.8 million transfusion units die as a result of these events. [23]

Febrile non-hemolytic transfusion reactions (FNHTRs)

The hallmark of febrile non-hemolytic transfusion reactions (FNHTRs) is an inexplicable rise in body temperature of at least 1°C that happens during or soon after transfusion. Antipyretic premedication may mask or lessen fever, but it usually doesn't stop the accompanying rigors and chills, which are caused by a systemic inflammatory response mediated by cytokines. Other possible causes of fever, such as bacterial contamination or acute hemolytic responses, should be ruled out before diagnosing FNHTR. Up to 30% of platelet transfusions have been linked to FNHTRs, which happen more frequently after platelet transfusions than after red blood cell transfusions. The storage of platelets at room temperature, which encourages leukocyte activation and cytokine buildup during storage, is thought to be the cause of this increased frequency. [24]

Allergic Reaction

One of the most frequent side effects of blood transfusions is allergic transfusion responses. Clinical signs could appear minutes or seconds after the start of the transfusion, or they could appear hours later. Recipient hypersensitivity to plasma proteins or other physiologically active ingredients in the transfused blood component causes these responses. Most instances are modest and manifest as localized skin rashes, pruritus, or urticaria.

Antihistamine medications, including diphenhydramine, are often effective in treating symptoms, and transfusions can frequently be resumed when the patient has been properly evaluated and the symptoms have subsided.[25]

Anaphylaxis

Anaphylactic transfusion reactions are rare but life-threatening, occurring in approximately 1 in 20,000–50,000 transfusions. They present with severe hypotension, shock, respiratory distress, and loss of consciousness. Commonly associated with anti-IgA antibodies, management requires immediate cessation of transfusion, prompt administration of epinephrine, and supportive care with continuous monitoring.[26-28]

Transfusion-related acute lung injury (TRALI)

A rare but dangerous transfusion reaction, transfusion-related acute lung injury (TRALI) usually happens six hours after transfusion, usually following plasma-rich components such fresh frozen plasma and platelets. It may result in respiratory failure and manifests as acute respiratory distress, severe dyspnea, and non-cardiogenic pulmonary oedema. Transfusions must be stopped right away, and supportive care—such as oxygen therapy and mechanical ventilation when needed—must be provided. Donor antibodies and recipient inflammatory factors are linked to TRALI. [29-30]

Transfusion-related Sepsis

A rare but potentially deadly consequence brought on by bacterial contamination of blood products is transfusion-related sepsis (TRS). Fever, tachycardia, rigors, or notable changes in blood pressure within ninety minutes following transfusion are its hallmarks. Isolating the same pathogen from the recipient's blood as well as the implicated blood component is necessary for diagnosis. Diversion of the first blood aliquot during collection and regular bacterial screening of platelet units before to transfusion are examples of preventive methods. [31-32]

Transfusion-associated circulatory overload (TACO)

A clinically relevant side effect of administering blood products is transfusion-associated circulatory overload (TACO), which carries a high risk of morbidity and death. Patients with pre-existing renal insufficiency, hypoalbuminemia, chronic heart failure (CHF), established fluid overload, or a history of plasma transfusion are among the patient categories that exhibit increased susceptibility to TACO. A variety of cardiopulmonary and vascular signs and symptoms, such as dyspnoea, orthopnea, cyanosis, tachycardia, jugular venous distension, and dependent pedal oedema, are evident in the clinical presentation of TACO. These characteristics show the pathophysiological effect of intravascular volume increase that surpasses the recipient's cardiac and pulmonary compensatory capability. The goal of therapeutic management is to implement supportive measures while simultaneously treating the underlying triggering reason.. In clinical practice, aggressive transfusion rate adjustment and early identification of at-risk patients continue to be essential for preventing TACO. [33-34]

Acute hypotensive transfusion reaction

When there are no other known causes of hypotension, a sudden and severe drop in blood pressure is the hallmark of a hypotensive transfusion reaction. It may appear as a single clinical finding, but when the transfusion is stopped and the proper supportive care is provided, it usually shows a quick and positive reaction. A treatment trial utilizing cleaned blood products is advised when hypotensive transfusion responses are still etiologically unexplained. Acute hypotensive transfusion reactions have been more commonly linked to bedside leukoreduction filters, however pre-storage leuko reduction filters have also been linked to cases. [35-36]

Transfusion-Associated graft-versus-host Disease (TA-GvHD)

Pyrexia, maculopapular eruptions that progress to hemorrhagic bullae, enterocolitis that manifests as copious watery diarrhea, hepatic dysfunction indicated by elevated liver function parameters, pancytopenia, and pathognomonic histological findings on tissue biopsy are all signs of transfusion-associated graft-versus-host disease (TA-GvHD), a serious clinical syndrome. This syndrome usually manifests eight to ten days after transfusion. Despite being

relatively uncommon, TA-GvHD is one of the deadliest transfusion-related complications due to its extraordinarily high case fatality rate of almost 90%. [37-38]

Hemovigilance Programme in India (HvPI)

On December 10, 2012, the Indian Pharmacopoeia Commission and the National Institute of Biologicals (NIB), Noida, introduced the Haemovigilance Programme of India (HvPI) as part of the Pharmacovigilance Programme of India (PvPI). Its goal is to use evidence-based interventions to improve patient safety by tracking, reporting, and analyzing transfusion-related adverse events. Nationwide data collection and analysis are made easier by the Hemo-Vigil program. The program involves more than 117 hospitals and medical schools. Advisory committees offer supervision, and NIB acts as the organizing hub. Additionally, HvPI wants to become a full member of the International Haemovigilance Network (IHN). [39]

Objective of reporting adverse Reactions and Transfusion in Hemovigilance program

The creation of a framework for national reporting; To create and maintain a strong national reporting system that facilitates the methodical gathering of information about adverse transfusion reactions and blood product-related incidents in all of India's registered healthcare facilities and acts as a strategic tool for advancing public policy on patient safety.

Hazard Recognition and Risk Evaluation: To enable the prompt detection of possible dangers, hazards, and systemic vulnerabilities related to the delivery of blood products and transfusions, hence offering crucial insights into areas where current systems need to be corrected**.**

Enhancement of Clinical Results and Patient Safety: The ultimate goal is to lower the risk of transfusion-related injuries, adverse events, and avoidable harm to future patients by converting reported data into focused improvement initiatives and evidence-based systemic reforms.

Encouragement of Accurate and Timely Reporting of Adverse Reactions: To promote efficient and proactive risk management by encouraging registered ADR Monitoring Centers, which include medical colleges, institutes, hospitals, and blood banks registered under the Pharmacovigilance National Co-coordinating Center, to promptly and accurately report any suspected adverse drug and transfusion reactions.

Strengthening of Product Safety Surveillance: To monitor and enhance the safety profile of blood components and biological products formed from plasma using hemovigilance data as an ongoing feedback mechanism, guaranteeing compliance with national and international quality and safety standards. [40]

Role and responsibilities of HvPI

Dedicated staff from transfusion medicine departments, blood banks, hospitals, and medical colleges around the country methodically record adverse transfusion reaction data and related events into the specialized Hemo-Vigil software platform. For centralized processing and supervision, the collected data are then sent to the National Institute of Biologicals' (NIB) HvPI National Coordinating Centre (HvPI-NCC). The HvPI-NCC is in charge of creating Standard Operating Procedures (SOPs) and guidance manuals after receiving the data and conducting a thorough examination of its quality and completeness. The Indian Pharmacopoeia Commission (IPC) is formally informed of the evidence-based recommendations that come from this review process.The Drug Controller General of India (DCGI), a division of the Central Drugs Standard Control Organization (CDSCO), receives the combined recommendations of the Haemovigilance Advisory Committee from the IPC. The DCGI-CDSCO, the highest regulatory body in this field, is tasked with developing and issuing regulations concerning the safety of blood and blood products. It is also in charge of informing all pertinent parties of these directives. [41]

Documentation and Reporting

Onset and causation are used to categorize transfusion responses. They can be infectious or non-infectious, acute (within 24 hours) or delayed (beyond 24 hours). Allergic responses, TRALI, TACO, and fever non-hemolytic transfusion reactions (FNHTR) are common acute non-infectious reactions; DHTR, TA-GVHD, and post-transfusion purpura are common delayed reactions. Bacterial contamination or transfusion-transmitted illnesses like HBV, HCV, HIV, and malaria can cause infectious responses. The most commonly reported responses are FNHTRs. The Transfusion Reaction Reporting Form (TRRF) and Hemo-Vigil software are used by India's Haemovigilance Programme to methodically gather, examine, and track adverse transfusion occurrences. [42-43]

Challenges in hemovigilance

Many nations lack efficient national hemovigilance systems, despite their significance. The lack of thorough blood transfusion policies, poor transfusion service coordination, and restricted donor-recipient traceability are some of the difficulties. These flaws make it more difficult to identify, report, and look into transfusion-related adverse events, which lowers the efficacy of corrective actions and may jeopardize patient safety and transfusion results. [44-45]

The establishment of efficient hemovigilance systems is hampered in many low- and middle-income nations by a lack of resources, infrastructure, and technical know-how. This frequently results in missed chances to detect avoidable risks and underreporting of transfusion-related adverse events. International cooperation can promote capacity building, knowledge exchange, and improved transfusion safety, while robust hemovigilance programs produce useful data for enhancing transfusion services. [46-47]

Future developments

Globally, transfusion safety has significantly improved more than 20 years after the first hemovigilance programs were established. Improvements in blood component processing, laboratory procedures, component selection, and clinical transfusion management have decreased the frequency of numerous transfusion reactions and transfusion-related mistakes. Despite these successes, the core objectives of hemovigilance—namely, the identification of uncommon or newly emerging adverse events and the advancement of transfusion medicine transparency—remain extremely pertinent. Strong haemovigilance systems are even more crucial in light of the COVID-19 pandemic. To assess the possible effects of SARS-CoV-2 infection and immunization on transfusion outcomes, ongoing surveillance is crucial. Patients with a history or current COVID-19 infection may be more susceptible to consequences such Transfusion-Related Acute Lung Injury (TRALI) or Transfusion-Associated Circulatory Overload (TACO) if they have hemovigilance. In a similar vein, observation could reveal whether blood donations from people who have just recovered or had vaccinations affect the incidence of transfusion responses. Additionally, haemovigilance studies that concentrate on particular patient groups can enhance knowledge of risk factors, aid in the creation of preventative measures, and help optimize transfusion practice. It is anticipated that digital technologies and electronic health data will play a major role in the future of hemovigilance. The detection and reporting of adverse transfusion events will be improved by the integration of electronic data sources, such as bedside monitoring systems and transfusion-associated vital indicators. By lowering the possibility of wrong transfusions, the widespread use of barcode scanning and computerized patient identification systems has already enhanced transfusion safety.

CONCLUSION

A crucial part of transfusion medicine is hemovigilance, which improves patient safety by methodically tracking, documenting, and analyzing transfusion-related side effects. It is essential for determining hazards, cutting down on mistakes, and raising the general standard of blood transfusion services. Strengthening hemovigilance systems can greatly increase transfusion safety, even though issues like underreporting, scarce resources, and poor infrastructure still exist in many nations. Additionally, new technologies like artificial intelligence, data analytics, and electronic health records have intriguing prospects for improved surveillance and early transfusion-related problem diagnosis. Sustained dedication to hemovigilance is necessary to guarantee safer transfusion procedures and improved patient outcomes globally.

ABSTRACT

Pentapartitioned neutrosophic strongly α-generalized semi closed sets and pentapartitioned neutrosophic strongly α-generalized semi open sets are presented in this study. Additionally, we examine their characteristics and behaviour in penta partitioned neutrosophic topological spaces.

Keywords: $\mathcal{P}n$set; $\mathcal{P}ns_{\alpha gs}$-$\mathcal{CS}$;$\mathcal{P}ns_{\alpha gs}$-$\mathcal{OS}$

INTRODUCTION

Uncertainty, indeterminacy, and inconsistency frequently arise in many real-world problems. To deal with such situations, the concept of the Fuzzy Set was first introduced by Lotfi A. Zadeh in 1965. Later, to overcome the limitations of fuzzy sets, the concept of Neutrosophic Set was proposed by Florentin Smarandache, which considers three independent membership components namely truth, indeterminacy, and falsity. Based on this concept, the Pentapartitioned Neutrosophic Topological Space has been developed as an extension of neutrosophic topology. This structure allows the study of generalized open and closed sets and their properties in a pentapartitioned neutrosophic environment. It also provides a foundation for defining new types of sets, mappings, and continuity concepts. In this paper, we introduce and investigate the concept of Pentapartitioned Neutrosophic Strongly α-Generalized Semi Closed Sets. Several properties and relationships between these sets are studied, and appropriate examples are provided to illustrate the concepts.

Preliminaries

Definition2. 1[5] Let Q be a universal set. An object of the form $K = \{< q, T_K, C_K, I_K, U_K, F_K >: q \in Q\}$is a $\mathcal{PnS}$ Kover Q where $0 \leq T_K + C_K + I_K + U_K + F_K \leq 5$. Here, $T_K(q)$ is truth membership,$C_K(q)$ is contradiction membership, $I_K(q)$ is ignorance unknown membership, $U_K(q)$is unknown membership, $F_K(q)$ is false membership.

Definition2. 2[10]Let Qbe a universal set. If the following three conditions are satisfied, then the collectionΓ of $\mathcal{PnS}$ over Q is known as a $\mathcal{PnTS}$ on Q:
(i)$0_Q, 1_Q \in \Gamma$,
$(ii) R_1, R_2 \in \Gamma \Longrightarrow R_1 \cap R_2 \in \Gamma$,
(iii)$\{R_i : i \in j\} \subseteq \Gamma \Longrightarrow \cup_{i \in j} R_i \in \Gamma$.
A $\mathcal{PnTS}$ is the term used to describe the pair(Q, Γ). Every component of$\Gamma$is called a $\mathcal{PnOS}$. A setR^C is considered as a pentapartitioned Neutrosophic closed set $\mathcal{PnCS}$ if $R \in \Gamma$.

Definition 2. 3[10] Let$K$be a $\mathcal{PnS}$in a $\mathcal{PnTS}Q$.Then: (i)$K$is called a$\mathcal{PnS}$-$\mathcal{OS}$ if $K \subseteq \mathcal{P}ncl(PNint(K))$ (ii)$K$is called a$\mathcal{P}n_\alpha$-$\mathcal{OS}$if $K \subseteq \mathcal{P}nint(\mathcal{P}ncl(\mathcal{P}nint(K)))$ (iii)$K$is called a$\mathcal{P}n$-$\mathcal{ROS}$ if $K = \mathcal{P}nint(\mathcal{P}ncl(K))$.
The complement of the above sets are respectively: $\mathcal{PnS}$-$\mathcal{CS}$,$\mathcal{P}n_\alpha$-$\mathcal{CS}$ and $\mathcal{P}n$-$\mathcal{RCS}$

Definition 2. 4[7]LetK be a $\mathcal{PnS}$ in a $\mathcal{PnTS}(Q, \Gamma)$. ThenKis called a $\mathcal{PnGS}$-$\mathcal{CS}$ if $\mathcal{PnS}$cl(K) ⊆ Uwhenever K ⊆ U and U is an $\mathcal{PnOS}$ in Q.

Definition 2. 5[6]A $\mathcal{PnS}$K in a $\mathcal{PnTS}(Q, \Gamma)$ is said to be $\mathcal{P}n_{agS}$-$\mathcal{CS}$ if $\mathcal{P}n_\alpha cl(K) \subseteq$ Uwhenever K ⊆ U and U is an $\mathcal{PnS}$-$\mathcal{OS}$ in (Q, Γ). The complement K^C of $\mathcal{P}n_{agS}$-$\mathcal{CS}$ is called a $\mathcal{P}n_{agS}$-$\mathcal{OS}$ in (Q, Γ).

RESULTS AND DISCUSSION

Pentapartitioned neutrosophic stronglyα-Generalized Semi Closed Sets

Definition 3.1.1. A Pentapartitioned neutrosophic Set K in (Q, Γ) is said to be a Pentapartitioned neutrosophic stronglyα-generlized semi closed set ($\mathcal{P}ns_{agS}$-$\mathcal{CS}$) if $\mathcal{P}n_\alpha cl(K) \subseteq U$ whenever $K \subseteq U$ and U is a $\mathcal{PnGS}$-$\mathcal{OS}$ in (Q, Γ).

Example 3.1.2.
Let $Q = \{u_1, u_2\}$.Let $\Gamma = \{0_{\mathcal{P}n}, U, 1_{\mathcal{P}n}\}$ be a $\mathcal{PnT}$ on Q, where $U =< q, (0.7,0.1,0.5,0.2,0.3), (0.6,0.3,0.5,0.3,0.4) >$.Then the$\mathcal{PnS}K =< q, (0.2,0.1,0.5,0.2,0.8), (0.3,0.3,0.5,0.3,0.7) >$ is a $\mathcal{P}ns_{agS}$-$\mathcal{CS}$ in (Q, Γ).

Theorem 3.1.3.Every $\mathcal{PnCS}$ in (Q, Γ) is a $\mathcal{P}ns_{agS}$-$\mathcal{CS}$ in (Q, Γ).
Proof: Assume that$K$ is a $\mathcal{PnCS}$ in (Q, Γ) . Let us consider a$\mathcal{PnS}K \subseteq U$where$U$ is a $\mathcal{PnGS}$-$\mathcal{OS}$ in Q. Since $\mathcal{P}n_\alpha cl(K) \subseteq \mathcal{P}ncl(K)$ and K is a $\mathcal{PnCS}$ in Q,$\mathcal{P}n_\alpha cl(K) \subseteq \mathcal{P}ncl(K) = K \subseteq U$ and U is $\mathcal{PnGS}$-$\mathcal{OS}$. That is $\mathcal{P}n_\alpha cl(K) \subseteq U$.Therefore,$K$ is $\mathcal{P}ns_{agS}$-$\mathcal{CS}$ in Q.

Example 3.1.4.
Let $Q = \{u_1, u_2\}$.Let $\Gamma = \{0_{\mathcal{P}n}, U, 1_{\mathcal{P}n}\}$ be a $\mathcal{PnT}$ on Q, where$U =< q, (0.8,0.1,0.5,0.2,0.2), (0.6,0.3,0.5,0.3,0.4) >$, then the $\mathcal{PnS}$ $K =< q, (0.1,0.1,0.5,0.2,0.9), (0.3,0.3,0.5,0.3,0.7) >$ is $\mathcal{P}ns_{agS}$-$\mathcal{CS}$ but not a$\mathcal{PnCS}$ in Q.

Theorem 3.1.5.Every $\mathcal{P}n_\alpha$-$\mathcal{CS}$ in (Q, Γ) is a $\mathcal{P}ns_{agS}$-$\mathcal{CS}$ in(Q, Γ).
Proof: Let K be a$\mathcal{P}n_\alpha$-$\mathcal{CS}$ in Q. Let us consider a$\mathcal{PnS}K \subseteq U$is a $\mathcal{PnGS}$-$\mathcal{OS}$in (Q, Γ). Since K is a $\mathcal{P}n_\alpha$-$\mathcal{CS}$,$\mathcal{P}n_\alpha cl(K) = K$.Hence $\mathcal{P}n_\alpha cl(K) \subseteq U$whenever$K \subseteq U$and U is$\mathcal{PnGS}$-$\mathcal{OS}$. Therefore K is $\mathcal{P}ns_{agS}$-$\mathcal{CS}$ in Q.

Example 3.1.6.
Let $Q = \{u_1, u_2\}$.Let $\Gamma = \{0_{\mathcal{P}n}, U_1, U_2, 1_{\mathcal{P}n}\}$ be a $\mathcal{PnT}$ on Q,

where $U_1 =< q,(0.4,0.1,0.5,0.2,0.5),(0.3,0.3,0.5,0.3,0.6) >$ and $U_2 =< q,(0.3,0.1,0.5,0.2,0.6),(0.2,0.3,0.5,0.3,0.7) >$, Consider a $\mathcal{PNS}\ K =< q,(0.8,0.1,0.5,0.2,0.1),(0.8,0.3,0.2,0.3,0.1) >$ which is$\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ in Q but not $\mathcal{PN}_{\alpha}$-$\mathcal{CS}$, since $\mathcal{PN}cl(\mathcal{PN}int(\mathcal{PN}cl(K))) = 1_{\mathcal{P}n} \nsubseteq K$.

Theorem 3.1.7.Every $\mathcal{PNR}$-$\mathcal{CS}$ in (Q,Γ) is a$\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$in (Q,Γ).
Proof: Let$K$be $\mathcal{PNR}$-$\mathcal{CS}$ in (Q,Γ) .Since every $\mathcal{PNR}$-$\mathcal{CS}$ is a $\mathcal{PNCS}$, K is a $\mathcal{PNCS}$ in (Q,Γ). Then,K is a $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$in (Q,Γ).

Example 3.1.8.
Let $Q = \{u_1,u_2\}$.Let $\Gamma = \{0_{\mathcal{P}n},U,1_{\mathcal{P}n}\}$ be a $\mathcal{PNT}$ on Q, where $U =< q,(0.6,0.1,0.5,0.2,0.4),(0.6,0.3,0.5,0.3,0.4) >\}$,Let us consider the $\mathcal{PNS}\ K =< q,(0.3,0.1,0.5,0.2,0.7),(0.2,0.3,0.5,0.3,0.8) >$, which is a$\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ but not $\mathcal{PNR}$-$\mathcal{CS}$in (Q,Γ) as $\mathcal{PN}cl\big(\mathcal{PN}int(K)\big) = 0 \subset K$.

Theorem 3.1.9. Every $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ in (Q,Γ) is a $\mathcal{PN}_{\alpha gs}$ -$\mathcal{CS}$ in (Q,Γ).
Proof: Assume that$K$is a$\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ in (Q,Γ). Let us consider $\mathcal{PNS}K \subseteq U$where$U$is a$\mathcal{PNS}$-$\mathcal{OS}$ in Q. Since every $\mathcal{PNS}$-$\mathcal{OS}$is a $\mathcal{PN}_{gs}$-$\mathcal{OS}$ and by hypothesis $\mathcal{PN}_{\alpha}cl(K) \subseteq U$, whenever $K \subseteq U$ and U is a$\mathcal{PN}_{gs}$-$\mathcal{OS}$ in (Q,Γ). We have $\mathcal{PN}_{\alpha}cl(K) \subseteq U$ whenever$K \subseteq U$and U is $\mathcal{PNS}$-$\mathcal{OS}$ in (Q,Γ). Hence$K$ is a$\mathcal{PN}_{\alpha gs}$-$\mathcal{CS}$ in Q.

Example 3.1.10.
Let $Q = \{u_1,u_2\}$.Let $\Gamma = \{0_{\mathcal{P}n},U,1_{\mathcal{P}n}\}$ be a $\mathcal{PNT}$ on Q, where $U =< q,(0.3,0.1,0.5,0.2,0.4),(0.8,0.3,0.5,0.3,0.2) >$, Then the $\mathcal{PNS}\ K =< q,(0.5,0.1,0.5,0.2,0.3),(0.2,0.3,0.5,0.3,0.3) >$ is a $\mathcal{PN}_{\alpha gs}$-$\mathcal{CS}$ but not a $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ in (Q,Γ).
Remark 3.1.11. The intersection of any two $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ is not a $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ in general as can be seen in the following example.

Example 3.1.12
Let $Q = \{u_1,u_2\}$.Let $\Gamma = \{0_{\mathcal{P}n},U,1_{\mathcal{P}n}\}$ be a $\mathcal{PNT}$ on Q, where $U =< q,(0.2,0.1,0.5,0.2,0.8),(0.4,0.3,0.5,0.3,0.6) >$, Then the $\mathcal{PNS}K_1 =< q,(0.3,0.1,0.5,0.2,0.6),(0.7,0.3,0.5,0.3,0.3) >$ and$K_2 =< q,(0.9,0.1,0.5,0.2,0.1),(0.4,0.3,0.5,0.3,0.5) >$ are$\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}inQ$.Now$K_1 \cap K_2 =< q,(0.3,0.1,0.5,0.2,0.6),(0.4,0.3,0.5,0.3,0.5) > \subseteq M =<$
$q,(0.4,0.1,0.5,0.2,0.3),(0.5,0.3,0.5,0.3,0.4) >$ and M is$\mathcal{PN}_{gs}$-$\mathcal{OS}$in but not a $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ in$Q$. But $\mathcal{P}\ n_{\alpha}cl(K_1 \cap K_2) = 1_{\mathcal{P}n} \nsubseteq M$. Therefore, $K_1 \cap K_2$ is not a $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ in$Q$.

Theorem 3.1.13. IfK_1 and K_2 are $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$, then $K_1 \cup K_2$is $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ in(Q,Γ).

Proof. If $K_1 \cup K_2 \subseteq M$ and M is $\mathcal{PN}_{gs}$-$\mathcal{OS}$. Then $K_1 \subseteq M$ and $K_2 \subseteq M$. Since K_1 and K_2 are $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$,$\mathcal{PN}_{\alpha}cl(K_1) \subseteq M$ and $\mathcal{PN}_{\alpha}cl(K_2) \subseteq M$ and hence$M \supseteq \mathcal{PN}_{\alpha}cl(K_1) \cup \mathcal{PN}_{\alpha}cl(K_2) = \mathcal{PN}_{\alpha}cl(K_1 \cup K_2)$. Thus $K_1 \cup K_2$ is $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ in(Q,Γ).

Pentapartitioned neutrosophic stronglyα-Generalized Semi Open Set

Definition 3.2.1. A $\mathcal{PNS}K$ is said to be Pentapartitioned neutrosophic strongly α-generlized semi open set ($\mathcal{PNS}_{\alpha gs}$-$\mathcal{OS}$) in (Q,Γ) ,if the complement $K^C$is a $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ in (Q,Γ).

Theorem 3.2.2. For any$\mathcal{PNTS}(Q,\Gamma)$, every$\mathcal{PNOS}$ is a $\mathcal{PNS}_{\alpha gs}$-$\mathcal{OS}$.
Proof: Let K be a $\mathcal{PNOS}$ in Q.Then$K^C$is a $\mathcal{PNCS}$ in Q. By Theorem 3.1.4,K^c is a $\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$ in Q. Hence K is a $\mathcal{PNS}_{\alpha gs}$-$\mathcal{OS}$ in Q.

Example 3.2.3.
Let $Q = \{u_1,u_2\}$.Let $\Gamma = \{0_{\mathcal{P}n},U,1_{\mathcal{P}n}\}$ be a $\mathcal{PNT}$ on Q, where $U =< q,(0.8,0.1,0.5,0.1,0.2),(0.6,0.1,0.5,0.1,0.4) >$, Consider the $\mathcal{PNS}K =< q,(0.9,0.1,0.5,0.1,0.1),(0.7,0.1,0.5,0.1,0.3) >$. Since$K^C$is a$\mathcal{PNS}_{\alpha gs}$-$\mathcal{CS}$, K is a $\mathcal{PNS}_{\alpha gs}$-$\mathcal{OS}$, but not $\mathcal{PNOS}$ in Q.

Theorem 3.2.4.In any $\mathcal{PNTS}(Q,\Gamma)$ every $\mathcal{PN}_{\alpha}$-$\mathcal{OS}$ is a $\mathcal{PNS}_{\alpha gs}$ - $\mathcal{OS}$.
Proof: Let K be a$\mathcal{PN}_{\alpha}$- $\mathcal{OS}$ in Q.Then K^{C} is a $\mathcal{PN}_{\alpha}$- $\mathcal{CS}$in Q. By Theorem 3.1.6, K^{C} is a $\mathcal{PNS}_{\alpha gs}$- $\mathcal{CS}$in Q. Hence $K$is a$\mathcal{PNS}_{\alpha gs}$- $\mathcal{OS}$ in Q.

Example 3.2.5.
Let $Q=\{u_1,u_2\}$.Let $\Gamma=\{0_{\mathcal{P}n},U_1,U_2,1_{\mathcal{P}n}\}$ be a $\mathcal{PNT}$ on Q,
where $U_1=<q,(0.4,0.1,0.5,0.2,0.5),(0.3,0.3,0.5,0.3,0.6)>$ and $U_2=<q,(0.3,0.1,0.5,0.2,0.6),(0.2,0.3,0.5,0.3,0.7)>$, Then the $\mathcal{PNS}$ $K=<q,(0.1,0.1,0.5,0.2,0.8),(0.1,0.3,0.2,0.3,0.8)>$ is a$\mathcal{PNS}_{\alpha gs}$ - $\mathcal{OS}$ in Q but not a $\mathcal{PN}_{\alpha}$- $\mathcal{OS}$ in Q.

Theorem 3.2.6. In any$\mathcal{PNTS}(Q,\Gamma)$, every $\mathcal{PNR}$- $\mathcal{OS}$ is a $\mathcal{PNS}_{\alpha gs}$- $\mathcal{OS}$.
Proof: Let$K$be $\mathcal{PNR}$- $\mathcal{OS}$ in (Q,Γ) .Then K^{c} is a $\mathcal{PNR}$- $\mathcal{CS}$in (Q,Γ). By Theorem 3.1.8,$K^{c}$is a$\mathcal{PNS}_{\alpha gs}$- $\mathcal{CS}$in (Q,Γ). Hence K is a $\mathcal{PNS}_{\alpha gs}$- $\mathcal{OS}$ in$Q$.

Example 3.2.7.
Let $Q=\{u_1,u_2\}$.Let $\Gamma=\{0_{\mathcal{P}n},U,1_{\mathcal{P}n}\}$ be a $\mathcal{PNT}$ on Q, where $U=<q,(0.6,0.1,0.5,0.2,0.4),(0.6,0.3,0.5,0.3,0.4)>\}$, Then the $\mathcal{PNS}$ $K=<q,(0.7,0.1,0.5,0.2,0.3),(0.8,0.3,0.5,0.3,0.2)>$, is a$\mathcal{PNS}_{\alpha gs}$- $\mathcal{OS}$ in Qbut not a$\mathcal{PNR}$- $\mathcal{OS}$ in (Q,Γ).

Theorem 3.2.8. In any$\mathcal{PNTS}(Q,\Gamma)$, Every $\mathcal{PNS}_{\alpha gs}$- $\mathcal{OS}$ is a $\mathcal{PN}_{\alpha gs}$ - $\mathcal{OS}$.
Proof: Let K be a$\mathcal{PNS}_{\alpha gs}$- $\mathcal{OS}$ in Q. Then $K^{C}$is a $\mathcal{PNS}_{\alpha gs}$- $\mathcal{CS}$ in Q. By Theorem 3.1.10, $K^{C}$is a $\mathcal{PN}_{\alpha gs}$ - $\mathcal{CS}$ in Q. Hence K is a $\mathcal{PN}_{\alpha gs}$ - $\mathcal{OS}$in Q.

Example 3.2.9.
Let $Q=\{u_1,u_2\}$.Let $\Gamma=\{0_{\mathcal{P}n},U,1_{\mathcal{P}n}\}$ be a$\mathcal{PNT}$ on Q, where $U=<q,(0.3,0.1,0.5,0.0.1,0.4),(0.8,0.1,0.5,0.1,0.2)>$. Then the $\mathcal{PNS}$ $K=<q,(0.2,0.1,0.5,0.1,0.5),(0.3,0.1,0.5,0.1,0.3)>$ is a $\mathcal{PN}_{\alpha gs}$ - $\mathcal{OS}$ in Q but not a $\mathcal{PNS}_{\alpha g}$ - $\mathcal{OS}$in Q.
Remark 3.2.10 The union of any two $\mathcal{PNS}_{\alpha gs}$- $\mathcal{OS}$ is not a $\mathcal{PNS}_{\alpha gs}$- $\mathcal{OS}$ in general.

Example 3.2.11
Let $Q=\{u_1,u_2\}$.Let $\Gamma=\{0_{\mathcal{P}n},U_1,U_2,1_{\mathcal{P}n}\}$ be a $\mathcal{PNT}$ on Q,
Where $U_1=<q,(0.2,0.1,0.5,0.2,0.8),(0.4,0.3,0.5,0.3,0.6)>andU_2=<q,(0.1,0.1,0.5,0.2,0.9),(0.5,0.3,0.5,0.3,0.4)>$ are$\mathcal{PNS}_{\alpha gs}$ - $\mathcal{OS}$ in$Q$. Now$U_1\cup U_2=<q,(0.6,0.1,0.5,0.2,0.3),(0.5,0.3,0.5,0.3,0.4)>$ is not a $\mathcal{PNS}_{\alpha gs}$- $\mathcal{OS}$in$Q$.

CONCLUSION

In this study, we introduce and analyze $\mathcal{PNS}_{\alpha gs}-\mathcal{CS}$ and discuss their essential properties. Future research may concentrate on extending these concepts to $\mathcal{PNS}_{\alpha gs}$ continuous and irresolute mappings.

ABSTRACT

Competition is evolving in the era of Artificial Intelligence (AI) rapidly reshaping the landscape in various industries around the globe. While AI-powered solutions are perceived primarily as something that can be implemented in large corporations, there has been a substantial number of business leaders in SMEs, accounting for approximately 30% of the Indian economy, using such solutions quite rapidly; at the same time, with more than 110 million employees, SMEs are in an early stage of using AI. The paper looks at the driving factors and constraints behind applying AI in Indian SMEs and how they affect business performance metrics like operational efficiency, sales expansion, customer satisfaction, and innovation ability. The study adopted a mixed-method research approach: Quant content derived from 312 SME owners and senior managers using a structured questionnaire across five industrial clusters of the state of Maharashtra, Karnataka and Gujarat; and Qual content obtained through deep interviews with 24 entrepreneurs and techno-consultants from the selected industrial clusters. Theoretical lens of the study: Technology–Organisation–Environment (TOE)-based perspective. The relationships are then tested using the Structural Equation Modelling (SEM). The three key enablers revealed include top management support, competitive clustering, and perceived technological readiness, indicative of the high importance of these for achieving AI adoption at least at a certain level. Financial constraints, skill shortage, and data privacy and protection issues constitute among the main obstacles identified. According to research, AI is helping enterprises that have adopted it improve their operational efficiency and customer experience metrics by up to 28.4% on average, compared with counterparts that have not adopted AI. The study recommends action points for policy interventions by both government and industry associations, as well as/action and capacity building programmes, subsidisation of tools enabled by AI, and the clarity of the data governance regime for the policy actors.

Keywords: Artificial Intelligence, SME, Technology Adoption, TOE Framework, India, Business Performance, Digital Transformation

INTRODUCTION

Artificial intelligence (AI) is being recognised as a common feature of the current global business environment, creating new opportunities for organisations through automated processes, insights gleaned from analysing large datasets, and the possibility of delivering mass-personalised customer experiences at scale (Davenport & Ronanki, 2018). AI is mainstream now in many ways, not only limited to some tech giants building hyper-intelligent chatbots or using predictive analytics to optimise their supply chains. More and more companies are considering how they might use AI strategically to enhance their competitiveness, regardless of size. The SME sector is often referred to as the backbone of the Indian economy, and it faces two-fold risks: domestic and international competitive pressures, and the rapid evolution of digital technology, which interact continuously and in multiple ways. Policies broadly fostering AI diffusion—particularly, the Digital India initiative of the Government of India and NASSCOM's (2020) National strategy for Artificial Intelligence. However, there is very little understanding (both empirical and conceptual) of how AI adoption manifests in Indian SMEs and its implications for performance. This study fills this gap by presenting an extensive empirical analysis of the drivers and consequences of AI adoption in Indian SMEs. Based on the TOE framework introduced by Tornatzky and Fleischer (1990), this paper focuses on technological, organisational and environmental factors of adoption, and the effect of its adoption on a multi-dimensional performance construct. The rest of the paper is organised as follows: Section 2 provides a literature review; Section 3 outlines the conceptual framework and hypotheses; Section 4 explains the research design; Section 5 reports the results; and finally, in Section 6, we discuss our findings and conclude with implications and future research directions.

LITERATURE REVIEW

AI Adoption in Organisations

Adoption of technology research has been conducted for a long time and has utilized models such as Technology Acceptance Model (Davis, 1989), Diffusion of Innovation Theory (Rogers, 1995) and Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh et al., 2003). For AI, Chui et al. (2018) indicates that three main value drivers are automation of cognitive tasks, better decision making, and predictive modelling. The findings of Mikalef et al., 2021 found that AI capability and dynamic organisational capabilities had a positive impact on data analytics maturity as mediation factor. The constraints of fewer resources and less IT infrastructure, and SMEs' risk aversion, all contribute to differences in adoption paths between SMEs and large enterprises, according to Arun, 2018. According to Bharadwaj et al., 2020 [+], Indian small and medium enterprises (SMEs) are more likely to adopt AI incrementally or step by step, beginning with the relatively less expensive solutions that utilize social media analytics, basic chat bots and eventually moving onto the moderately more advanced applications like predictive maintenance and demand forecasting.

TOE Framework and Digital Technology Adoption

The TOE framework has been frequently used to articulate enterprise technology adoption decisions. Technological context refers to internal and external technologies used by the firm, organisational context includes firm size, managerial support and financial resources, and environment context captures industry structure, competitive forces and government policy (Tornatzky & Fleischer, 1990). The generalizability of the TOE has been confirmed by Oliveira and Martins (2011) for different types of technology: cloud computing, ERP and e-commerce. More recently, Mishra et al. L29: (2022) used TOE to assess AI adoption readiness of manufacturing SMEs in emerging markets and found significant effects for all three contextual dimensions.

Performance Outcomes of AI Adoption

Empirical evidence relating AI integration to business performance suggests positive correlations with the magnitude differing by sector, firm size and how deep in the value-chain the implementation is carried out. Bughin et al. (2017) find that early among industries, profit margins on average advance over non-adopters by 3 to 15 percentage points (pp). Agrawal et al. Prediction improvement is, therefore, one key mechanism through which performance can be improved by AI (Ransbotham et al., 2019). This helps lower uncertainty in decision making across many domains—e.g., hiring, inventory management and credit risk assessment. The evidence base in this area is still nascent and lacking in empirical insights specifically for SMEs – Kaartemo & Helkkula (2018) further make the case that more contextually appropriate research reflecting common resource profiles of smaller firms in emerging economies, as well as the institutional environments they are embedded into, would find a greater home.

Conceptual Framework and Hypotheses

Using the TOE framework, this research posits that AI adoption in Indian SMEs is driven by three categories of factors: (i) technological readiness and perceived usefulness (technological context), (ii) top management support, organisational size and financial capacity (organisational context), and finally (iii) competitive intensity, government policy support, and partner ecosystem (environmental context). In turn, it is theorised that adopted AI will enhance business performance in four key areas: operational efficiency, revenue generation, customer satisfaction, and innovation competence.

The following hypotheses were formulated:
H1: The 'technological readiness' variable positively affects AI adoption in Indian SMEs
H2: Top Management Support has a positive effect on AI Adoption.
H3: Financial capacity positively moderates the relationship between technological readiness and AI adoption
H4: AI adoption is significantly driven by the competitive pressure in the environment.
H5: Embracing AI has a positive effect on operational efficiency
H6: AI innovation has a positive impact on customer satisfaction and revenue growth.
H7: AI adoption has a positive impact on innovation capability in SMEs

RESEARCH METHODOLOGY

Research Design

A convergent mixed method design was used in the study. To confirm and enrich the statistical findings qualitative interviews were held after quantitative data collection was carried out. This is congruent with Creswell and Plano Clark's (2017) guidelines for studies studying complex phenomena in organisational research where the trends in the numerical data can be better understood when supported by contextualization.

Sample and Data Collection

SMEs dispersed across the three industrial clusters of Pune (Maharashtra), Bengaluru (Karnataka) and Surat (Gujarat) forms the quantitative sample consisting of 312 SMEs. The study was conducted using stratified random sampling methods of all sub-sectors of manufacturing (118), services (104) and trading (90). From October 2023 to March 2024, a structured questionnaire (48 items; measured on a five-point Likert scale) was administered to owners or senior managers. We achieved 78.3% response rate. Using purposive sampling technique, 24 participants were selected for the qualitative component; they are SME owners who have gone through an AI implementation and technology consultants that have SME focus. Conducted semi-structured interviews, recorded, transcribed, and analyzed the interviews, each taking 55 minutes on average.

Measures

All constructs included were redefined with valid multi-item scales employed in previous studies. For measuring the technological readiness, items developed by Parasuraman (2000) were adopted. The items of top management

support were modified from Liang et al. (2007). We measured performance outcomes with items based on the Balanced Scorecard (Kaplan & Norton, 1996). All factor loadings > 0.70 were found indicating construct validity using confirmatory factor analysis (CFA). The composite reliabilities for each construct ranged from 0.81 to 0.93 and the Average Variance Extracted (AVE) values were all greater than 0.50 for each construct, respectively, which met the convergent validity and discriminatory validity requirements.

Analytical Procedure

IBM AMOS 27.0 software was used for the analysis technique of the Structural Equation Modeling (SEM). Model fit analysis was done based on common indices: Chi-square by degree of freedom (χ^2/df), Comparative Fit Index (CFI), Tucker-Lewis Index (TLI), Root Mean Square Error of Approximation (RMSEA) and Standardised Root Mean Square Residual SRMR. Harman's one factor test was used to look at the common method bias, but there is only 23.6% variance, which does not suggest that there was common method bias in the data.

RESULTS

Sample Profile

Table 1 presents the demographic profile of the surveyed enterprises. The sample is predominantly composed of micro and small enterprises (combined 71.5%), with annual turnover below INR 25 crore. Manufacturing firms account for 37.8% of the sample.

AI Adoption Status

Of the 312 respondents, 134 (42.9%) reported having adopted at least one AI-enabled application in their business operations. The most commonly adopted applications were customer-service chatbots (61.2% of adopters), social media analytics (54.5%), and inventory/demand forecasting tools (43.3%). Full-scale AI integration across multiple business functions was reported by only 8.2% of the sample, reflecting the predominantly incremental nature of adoption.

SEM Results

The SEM model demonstrated acceptable fit: Chi-square/df = 2.14, CFI = 0.95, TLI = 0.94, RMSEA = 0.061, SRMR = 0.058. The SEM path diagram presents the overall model structure: The left side are the three antecedents which act as predictors while the right side are the four outcomes, with AI Adoption as the mediator in the middle. Inside each box the path coefficient (β) and significance level is displayed. Click any node to delve deeper into that node. Some points to note here in the model: The path towards Operational Efficiency is the strongest outcome path (β = 0.52) and the path towards Tech Readiness is the most influential antecedent (β = 0.48). The weakest Antecedent Outcome path is between Competitive Pressure and Innovation Capability with a value of (β = 0.33) and the weakest A-O is between Competitive Pressure and HRM Path with (β = 0.35). Both are highly significant. To test the moderation hypothesis H3 which posits that technology readiness–adoption relationship can be moderated by financial capacity, a multi-group SEM approach was used. The results showed a significant moderation effect ($\chi^2$2 = 8.74, $p < 0.05$), with the technology readiness path being significantly higher of finance rich SMEs (β = 0.61) than finance constrained SMEs (β = 0.29).

DISCUSSION

The results are mostly consistent with the suitability of the TOE framework for probing the AI adoption environment in the emerging market SME domain. Technological readiness is also the most common driver across all other studies cited in this article has found that suitable basic technological digital infrastructure and IT literacy is a prerequisite to the use of AI (Mishra, 2022). While top management support is known to play an important role in technology acceptance (Liang et al., 2007), this is not the second factor that is discussed. Competitive pressure is cited by 33% of those surveyed as the third most important factor challenging the growth of small businesses, supporting the claim

that it is increasingly timely to consider AI as an operational tool, rather than a luxury. Through interviews it was seen that there were three challenges – access to funding, access to skill ful workforce, and data privacy – which were structural barriers Indian SMEs are coming across when trying to go digital. Many interviewees were using AI tools within their business that happened to be free of charge, or used for little to no cost, and these folks would describe what I'm going to call an 'AI awareness gap': they were not particularly conscious of which AI tools were suitable to their specific business model or where to begin without shelling out a lot of money. This discovery becomes directly applicable to support programme designing by the industry associations and the governments. The emphasis on performance indicates a strong link between the use of AI and operational efficiency ($\beta = 0.52$), aligning with the estimates by McKinsey Global Institute that suggest AI automation can reduce costs by up to 30% in labour-intensive industries. The gains in terms of innovation capability are large, but still fairly small ($\beta = 0.35$), suggesting that the innovation dividend of AI adoption is lagged, and for instance at longer stages of maturity and/or organisational learning within SMEs.

CONCLUSION

This research systematically maps the empirical evidence on the dynamics of the adoption of AI, and yields valuable insights for technology adoption in an emerging small business context, which has been relatively under-researched: Indian SMEs. The data confirm the hypothesized performance benefits, which are well reflected in the TOE framework, which is a multidimensional antecedent to the adoption (SEM) of the product. The findings suggest that AI toolkits targeted at the SME use case may need to be subsidized by the government, capacity building workshops via industry clusters, and more accessible compliance guidelines to dampen the anxiety around compliance without sacrificing privacy safeguards and best practices. Only a few industry associations such as Confederation of Indian Industry (CII) and Federation of Indian Chambers of Commerce & Industry (FICCI) can provide networking platforms to help members learn from one another, with the small AI diffusion projects helping each other address real-life challenges they have faced in the process.

Implications

Some of the recommendations from the insights leave the owners and managers of SMEs with a roadmap for using the power of AI – from making obvious and immediate wins to ensuring they have internal faith and have concrete return on investment before they ramp up the use of AI. There are some limitations to the study. The cross-sectional design makes it impossible to make causal inferences on performance trends over time. The sample is geographically restricted to 3 industrial clusters in India and thus the generalisability is restricted. Randomized controlled trials over an extended period are needed, extending to more sparsely studied states and at more granular a level of analysis of sector specific adoption trends. Future studies should examine other factors that might impact the relationship between adoption and expected performance such as the quality of AI vendors, the reliability of cloud infrastructure, and the availability of fintech credit.

ABSTRACT

The research reveals the utilisation of digital payments and the transformations noted by customers in the Tiruchirappalli district as a result of technological advancements. Digital wallets and e-payment systems have undergone significant simplification, leading to a widespread adoption of these transactions across the customer market. Online payment is considered as a highly secured payment mode by the customers as there is proper security process especially the encryption and biometric verification system. The increased awareness on digital payment is caused because of the training and guidance as well as the marketing influence. In addition to social media impact, Word-of-mouth and simple procedures are the main elements in easy adopting of digital payments. Such elements have led to the acceptance and high recognition of increased usage of digital payment in Tiruchirappalli district.

Keywords: Consumer, Digital Payment, Social media impact, Security measures, Technology

INTRODUCTION

The technological developments have influenced the adoption of digital payments and it also has a significant impact on the consumers interaction towards financial services. Digital transactions are nowadays more secured, quick, and user-friendly. They include inventions from mobile payments, AI and blockchain technology. Such changes and developments offer the customers with more confidence and convenience to drive the adoption rates. Still there are certain concerns about the security and legal systems. These issues need to be dealt essentially to ensure the continued development and the method to assist the consumers using digital payment systems. The technological developments must be appreciated that have transformed the financial landscape in the recent years in Tiruchirappalli district. Mobile payments, and digital wallets that have brought a matchless level of simplicity and efficiency have transformed the methods of payments among the consumers. These transformations have made the user-friendly approach for the consumers to make simple and secured transactions using their mobiles by reducing the necessity of money. The implementation of two-factor authentication, biometric authentication, and encryption has emerged as an essential component in tackling the concerns surrounding fraud and data breaches. This has increased the trust of the consumers on the digital payment service providers. Adoption of these digital payments have further influenced the safe usage and payments through effective marketing operations and guidelines.

REVIEW OF LITERATURE

Subramanian Shanmugam. (2022). **"**Digital Transformation through Fintech: An Analytical Study". concludes that the majority of Indian fintech start-ups are not older than ten years, but these corporations have achieved gigantic steps over the past few years, especially in the domains of financing tech and insurance firms. Siddaraju. S (2023), "A Study of Consumer Perceptions on Digital Payment System in India with Special Reference to Mysore District". established that age and consumer perception of the digital payment system are associated, and further established the lack of significant association between gender and educational background and consumer perception of the digital payment system. Phuong Thanh Thi Tran. et. al. (2023). **"**Digital Transformation of the Banking Industry in Developing Countries". revealed that digital banks provide flexible goods and services, which have multiple benefits at a high level of involvement, such as increasing the revenues of operations and strengthening the relationship between users and banks. Kamboj, Kuldeep Kumar, et al. (2024). "A study of drivers and inhibitors of user acceptance of digital payment systems in India". results showed the importance of such factors as perceived risk, trust, and financial literacy in the digital era in customer behaviour. These findings can be used to improve the adoption and revenues among the industry players. Karmaker, S., et al., (2025). "Exploring influential factors of consumer purchase behavior on the adoption of digital payment apps in Bangladesh**,** results prove that the maximum giant variables affecting purchaser behaviour within the framework of virtual payment applications are the familiarity with the emblem, its availability, protection, age, earnings, and consumer perception, because the maximum critical ones.

STUDY OBJECTIVES

- The purpose of this study is to examine the correlation between the factors that influence digital payments and the opinions of consumers on the adoption of digital payments.
- In order to ascertain the opinions of the adoption of digital payment methods by consumers in the Tiruchirappalli district

RESEARCH METHODOLOGY

To better understand the perspectives of customers who make use of digital payments methods, a structured questionnaire was used. The method of research known as descriptive research was used in the execution of this

investigation. Consumers who make use of digital payments methods in the Tiruchirappalli district, which is located in the state of Tamil Nadu, are included in the general population that is being analysed for the purpose of the study. In order to collect information for a sample size of 113 customers that make use of digital payments, a simple random sampling strategy is used. This strategy makes use of a well-structured questionnaire that was prepared and circulated. 150 questionnaires were distributed from which 27 were incomplete and 12 were not returned. For this reason, a total of 113 questionnaires that were filled out were used for the research.

DATA ANALYSIS

To analyze the impact of technological advancements on consumer adoption of digital payments in Tiruchirappalli district, several key variables are used in the study. They are explained in the table 1. From table 2 the demographic of older people is the most active in adopting digital payments methods, as shown by the fact that 56.6% of digital payments users are between the ages of 30 and 40 when it comes to using digital payments methods. Those aged 50 and over make up the second biggest category, accounting for 19.5% of the total, which indicates that older folks are becoming more comfortable with technology each year. The percentage of females (54.9%) who use digital payments is somewhat higher than the percentage of males who use them (45.1%), which may indicate that women are more engaged than men. The majority of users have credentials from higher education, with 38.9% of them having postgraduate degrees. Graduates represent 27.4% of the user population, while diploma holders make up 25.7% of the user population. The fact that just 8.0% of people have completed schooling suggests that a higher level of educational achievement is connected with a greater number of people using digital payments methods.

Hypothesis I

Null Hypothesis: There is a positive relation among Factors Influencing Digital Payments and Opinion on Consumer Adoption of Digital Payments

The hypothesis is used to explore the relationship between the factors that impact digital payments and the attitudes of consumers towards the adoption of digital payments systems. This relationship is studied within the framework of the hypothesis. The Pearson correlation approach is used by the Inter Correlation Matrix in order to ascertain the specific nature of this association. In table 3, according to the Pearson correlation coefficient of 0.961, the following factors have a significant impact on digital payments: Consequently, this suggests there is a very high positive link between the elements that influence digital payments and the attitudes of consumers towards the adoption of digital payments. Statistics (two-tailed) = 0.000: If the hypothesis to be null is correct, then this p-value indicates the chance of witnessing the data rather than the alternative. The assumption that the link is statistically significant is strongly supported by the fact that the value is 0.000, which is significant at the 0.01 level. There is a strong and statistically significant relationship between digital payments factors and customer sentiments towards digital payments. The considerable positive correlation (0.961) and the extremely low p-value (0.000) demonstrate that this relationship exists. This indicates that as the number of favourable elements that influence digital payments rises, the number of customers who are ready to use digital payments methods likewise gradually increases.

Opinion on Consumer Adoption of Digital Payments is the dependent variable, and Table:3 displays the multiple correlation coefficient R (0.984). Total dependent variable variance is R square. Additionally, the R square value is 0.868 (86.8%), indicating a strong match.

Hypothesis II

Null Hypothesis: There is a positive relation among Opinion on Consumer Adoption of Digital Payment

Dependent Variable: Opinion on Consumer Adoption of Digital Payments **Predictors:** (Constant), FIDP1, FIDP2, FIDP3, FIDP4, FIDP5, FIDP6, FIDP7, FIDP8, FIDP9, FIDP10

The purpose of the hypothesis is to determine whether or not there is a substantial disparity in the opinions on the adoption of digital payments by consumers. This association may be determined with the use of the regression

analysis. The value of 1158.490 for the regression value in table 5 represents the amount of variance in consumer adoption of digital payments that can be explained by the model. F-Statistic (8.977): This number is used to determine whether or not the model is significant in general. When the F-statistic is larger, it suggests that the predictors provide a substantial explanation for the variance in the variable that is being predicted. Sig. (0.000): The p-value indicates the probability of seeing the data if the null hypothesis is valid. The model is statistically significant since its 0.000 value is 1% significant. The low p-value (0.000) shows that consumer views of digital payments methods vary. We can reject the null hypothesis since the model parameters have a significant influence on customer views of digital payments systems.

The relevance of the many variables that influence consumer adoption of digital payments is shown in the table 6 that presents the results of the regression analysis. If the null hypothesis is correct, the significance level, also known as the P-value, indicates the likelihood of witnessing the effect. A statistically significant result is shown by a number that is less than 0.05. Convenience and ease of the use were assessed, and the results showed that (B = 2.042, Beta = 0.391, t = 4.573, p = 0.000): When it comes to the adoption of digital payments methods by consumers, this element has a very substantial and beneficial influence. It is possible to drastically increase adoption rates by making the product more convenient and user-friendly. The following are the enhanced security features: B = -1.321, Beta = -0.386, t = 3.492, p = 0.001: Interestingly, this element has a large negative influence, which may suggest that even if customers place a high value on safety, excessively complicated safety precautions may discourage them from using the product. Technological improvements (B = 1.914, Beta = 0.418, t = 4.409, p = 0.000): The adoption rate is positively impacted by technological improvements such as mobile payments systems and digital wallets. This effect is extremely significant and beneficial. The following variables were found to be significant: B = 1.708, Beta = 0.336, t = 3.349, p = 0.001: A considerable number of customers are greatly encouraged to embrace digital payments methods when prizes and incentives are offered. Trust and Reliability (B = -0.789, Beta = -0.202, t = 2.310, p = 0.023): Trust in payment providers has a large negative influence, which may imply that problems with trust might severely discourage adoption. This is supported by the fact that the beta value is 0.802. (B = 0.360, Beta = 0.073, t = 0.890, p = 0.376) With regard to the policies and regulations of the government: The finding that this component does not have a statistically significant impact suggests that while supporting policies are essential, they may not be sufficient to encourage consumer adoption on their own. (B = 2.218, Beta = 0.472, t = 4.243, p = 0.000) The following are the recommendations made by peers: In order to emphasise the significance of social influence, it is important to note that recommendations from peers and social networks have a very significantly beneficial effect. (B = 0.409, Beta = 0.092, t = 1.133, p = 0.260) Access to Financial Services Access to financial services. The results were not statistically significant, which suggests that just offering access is not sufficient to induce adoption. The following are examples of successful marketing campaigns: B = 0.399, Beta = 0.088, t = 0.966, p = 0.336 In addition, this is not substantial, which suggests that while marketing is essential, it may be necessary to combine it with other elements in order for it to be successful. (B = -0.629, Beta = -0.148, t = -1.373, p = 0.173) The fact that the results were not statistically significant suggests that cultural acceptability does not have a substantial influence on adoption on its own.

Through the use of Varimax rotation, Principal Component components Analysis was able to make the discovery of a structure that was composed of four components. Every single one of the components has an eigen value that is higher than one, as shown by the Total Variance of Factors Influencing Digital Payments (table:8) and the sum of the eigen values of components 1, 2, 3, and 4 accounts for 69.11% of the total variance. A total of thirty-one percent of the instrument's 10 elements have been removed from consideration.

The Principal Component Analysis of the Factors That Influence Digital Payments in table 9 is presented Down Below:User satisfaction, usability, and accessibility are all improved when the interface design, navigation, and mobile compatibility are simplified pertaining to digital payments systems (0.899 and FIDP2)The impact of social media, word-of-mouth, and online assessments all contribute to a growth in the validity of digital payments systems, as well as their acceptance and the number of alternative payments methods available to consumers. values of 0.758 for the FIDP3 The acceptance, adaptation, and behaviour of digital payments systems are all influenced by a variety of factors, including the preferences of consumers, various cultural tolerances, and disparities across generations.

values of 0.880 for the FIDP7.Consumers' shopping habits and their usage of digital payments methods are influenced by rewards programs, cashback offers, and economic incentives.780 for the FIDP10 Encryption, biometric identity, and two-factor authentication are all strategies that may be used in digital payments systems to increase consumer trust and confidence while also protecting against fraud (0.783 by the FIDP1) When blockchain technology, artificial intelligence, and mobile payment platforms are combined, digital payments systems increase in terms of their efficiency, reliability, and security (FIDP5 score of 0.762) As a result of fee waivers, discount offers, and decreased transaction costs, digital payments are more enticing to consumers since they are more affordable (0.562 for the FIDP4). Increasing the level of knowledge, trust, and acceptance of digital payments technologies may be accomplished via marketing, education, and awareness initiatives. The rise in the number of individuals who use digital payments systems, as well as an increase in economic engagement and market penetration, may be attributed to a variety of factors, including access to banking, development of digital literacy, and outreach to rural regions. FIDP8 0.711 Legitimacy, market growth, and consumer protection from government policies, legal frameworks, and compliance requirements are all factors that favour the use of digital payments methods at a FIDP6 of 0.578.

A structure consisting of four factors was discovered by Principal Component Factor Analysis by using Varimax rotation. According to the Total Variance of Opinion on Consumer Adoption of Digital Payments (table:11), all of the components have an eigen value that is greater than 1,, and the components 1, 2, 3, and 4 together explain a total of 73.13% of the variance. Seventy-seven percent of the total ten items on the instrument have been removed from consideration.

The table that presents the results of the Principal Component Analysis (PCA) offers insights into the primary elements that influence the adoption of digital payments by consumers. The table provides a list of the variables that influence the adoption of digital payments methods, together with the items and factor loadings that correlate to each factor. Indicative of greater correlations with the underlying component are factor loadings that are relatively higher. The coefficient of recommendation from peers (CADP7) is 0.843, which indicates that recommendations have a considerable impact on consumer uptake. Enhanced security features (CADP2) = 0.756: Security measures such as encryption and biometrics play an important part in the overall security system performance. It is important to note that marketing and educational activities are essential drivers. Effective marketing campaigns (CADP9) = 0.754 Access to financial services is provided by digital payments (CADP8) = 0.753: Acceptance of digital payments is increased when financial services are readily available. Rewards and incentives (CADP4) = 0.681 There is a correlation between cashback and rewards and the behaviour of consumers. Taking into account cultural characteristics, adoption rates are influenced by cultural acceptability (CADP10) = 0.777. Adoption is driven by technological breakthroughs (CADP3), which are 0.766. Examples of such innovations are mobile payments and digital wallets. Policies of the government (CADP6) equal 0.846: Use is encouraged by rules that are supportive. In terms of user-friendliness, convenience and ease of use (CADP1) = 0.835 is an important criterion to consider. There is a considerable relationship between trust in payment providers and adoption. The CADP5 value for trust and dependability is 0.955.

RESULTS AND DISCUSSION

The significance of social identity is shown by the fact that the consumer's adoption of digital payment method is highly impacted through social networks and references from others. By increasing the operations of security measures and ensuring the secured payment service providers are reliable and these are the vital elements in establishing customer confidence. Effective marketing campaigns and guidelines with proper training significantly assist in instructing and influencing consumers that leads to their success. Cashback schemes, rewards, and similar initiatives improve customer engagement and adoption via financial support. The development of technology and social acceptance of digital payment methods significantly attract their adoption. All the adoption rates are being developed by the support of government policies and regulations that also, promote the usage of digital payment systems. Due to the current status of technology, consumers in Tiruchirappalli district have started adopting the

digital payment methods more frequently than others. Touch-free payments, digital wallets, and mobile payment systems have increased more transactions among the consumers. the cash usage has been reduced due to theses optimised payment. Encryption, bibliometric identification, two-factor authentication have increased the trust of the consumers using digital payments. Various explanations have enabled the widespread usage of digital payment methods in the Tiruchirappalli district. The honesty followed by these new technologies and the agreeing experience they provide explain their consumer demand. The any time and any place digital payments has highly improved the purchasing experience of the consumers. Also, the enhanced security measures have significantly decreased consumer fear over data breaches and fraud, hence it increases their readiness to use digital payment methods. The effectiveness of marketing efforts made, guidelines and awareness has suggestively influenced the process of developing awareness about the benefits of digital payments and their secured applications. Social inspiration and word-of-mouth have also been significant factors boosting the extensive adoption of digital payment systems. Nowadays, consumers have become more motivated to adopt new technology when they see others using them successfully. The high impact that technology developments have made recently has assisted the consumers in the Tiruchirappalli district to adopt digital payments. The acceptance and adoption of digital payment in Tiruchirappalli district has been considerably encouraged by technological innovations. Non-comparable simple and effective method has come from mobile payments, digital wallets, and contactless payments that transform day-to-day transactions. Security facts such as biometric endorsement and encryption have increased the consumer trust, thus lowering fraud and data breach. Effective marketing and training help the stakeholders to highlight the advantages and usage of digital payments. Social networks and peer endorsements have also motivated the adoption of digital payments. Furthermore, better government rules and legislations also have simplified the digital transactions. These features assist the consumers from Tiruchirappalli district to accept and utilise digital payments effectively and frequently.

ABSTRACT

Emdogain is an enamel matrix derivative biomaterial and its role in Pediatric Dentistry has evolved beyond conventional periodontal applications and now includes regenerative endodontics, management of dental trauma, pulpotomy agent, root development support, soft tissue healing and preservation of immature teeth. The biological activity of Emdogain is primarily attributed to amelogenin-rich proteins capable of stimulating cementogenesis, periodontal ligament regeneration, osteogenesis, angiogenesis, and cellular differentiation. Over the last two decades, growing evidence has highlighted its capacity to improve wound healing and promote regenerative events within the oral cavity. This review critically evaluates the composition, biological mechanism, indications, clinical applications, advantages, limitations and future perspectives of Emdogain in pediatric dentistry.

Keywords: Emdogain, Enamel Matrix Derivative, Pediatric Dentistry, Biomaterials, EMD

INTRODUCTION

Emdogain, a commercially available "enamel matrix derivative (EMD)", represents one of the most extensively studied regenerative biomaterials in dentistry[1]. Originally introduced for periodontal regeneration but now Emdogain has demonstrated potential applications in several pediatric dental procedures. The biomaterial contains proteins derived from developing porcine tooth buds, predominantly amelogenins, which mimic developmental events occurring during tooth formation [2]. These proteins influence cellular attachment, proliferation, differentiation, and matrix formation. Emdogain may stimulate periodontal ligament fibroblasts, osteoblasts, cementoblasts, and mesenchymal stem cells [3]. Emdogain has attracted considerable attention due to their regenerative and anti-inflammatory properties. Concept of enamel matrix proteins influencing periodontal regeneration originated from developmental biology observations. During tooth development, Hertwig's epithelial root sheath secretes enamel matrix proteins that guide cementogenesis and periodontal attachment formation [4]. As regenerative dentistry evolved, researchers explored the role of Emdogain in pulp therapy, avulsed teeth management, root resorption management, and regenerative endodontic procedures [5]. Pediatric dentistry became a particularly relevant field because immature permanent teeth exhibit remarkable healing potential and several biological properties make Emdogain beneficial in pediatric dentistry

- Biocompatibility
- Bioactivity
- Anti-inflammatory effects
- Promotion of angiogenesis
- Stimulation of hard tissue formation
- Enhancement of periodontal ligament regeneration

Composition of Emdogain

Emdogain® is the commercial preparation of EMD marketed by Straumann Group (Fig. 1). Emdogain is a sterile gel primarily consists of amelogenin proteins (Derived from developing porcine tooth buds) suspended within a propylene glycol alginate (PGA) carrier6. Approximately 90% of the protein fraction comprises amelogenins, while the remaining proteins include enamelin, tuftelin, and ameloblastin [7]. The gel formulation allows controlled application to root surfaces or surgical sites. Upon contact with physiological fluids, the carrier precipitates and forms an insoluble extracellular matrix layer that facilitates cell adhesion and differentiation [8].

Mechanism of Action

The regenerative capacity of Emdogain is linked to molecular signaling pathways involved in tissue development. Amelogenins influence cytokines, growth factors, extracellular matrix proteins responsible for wound healing and regeneration [9] Emdogain stimulates "transforming growth factor-beta (TGF-β)", "bone morphogenetic proteins (BMPs)" and "vascular endothelial growth factor (VEGF)" pathways [10]. These pathways enhance angiogenesis and matrix mineralization. Emdogain also promotes proliferation and differentiation of periodontal ligament stem cells[11]. In immature permanent teeth, this biological activity may support continued root development and apical closure. Another significant property is modulation of inflammatory responses. Emdogain appears to suppress pro-inflammatory cytokines while enhancing regenerative cellular events [12], and this effect may be advantageous in traumatized or inflamed teeth.

Applications in Pediatric Dentistry

Direct Pulp Capping

Direct pulp capping is performed to preserve the vitality of exposed pulp tissue. EMD promotes odontoblast-like cell differentiation and reparative dentin formation, thereby facilitating pulpal healing and reducing inflammatory responses[13,14]. These properties make it a potential alternative biomaterial for vital pulp therapy.

Pulpotomy

EMD has been evaluated as a pulpotomy medicament in primary and immature permanent teeth. Its regenerative potential encourages dentin bridge formation and maintenance of radicular pulp vitality contributing to successful clinical outcomes [13,14].

Regenerative Endodontic Procedures

Regenerative endodontic procedures aim to restore the vitality of immature permanent teeth with necrotic pulp. EMD has been shown to stimulate cell proliferation, angiogenesis, and differentiation of progenitor cells thereby supporting continued root maturation and apical closure[13,15]. When EMD is used as a biologically active scaffold during regenerative treatment, it has demonstrated favourable healing outcomes [15].

Periodontal Regeneration

In adolescent patients presenting with localized periodontal defects, EMD has demonstrated the ability to promote regeneration of cementum, periodontal ligament, and alveolar bone rather than simple repair[16,17]. Clinical studies have reported improvements in attachment levels and periodontal healing following its use.

Role in replantation

Emdogain has been proposed as an adjunctive regenerative material due to its ability to support periodontal ligament regeneration as well as reduce inflammatory root resorption. Periodontal healing is improved following replantation of avulsed tooth treated with EMD. The material may reduce ankylosis and external inflammatory resorption enhancing periodontal ligament cell survival [18]

Safety and Biocompatibility:

EMD, commercially marketed as Emdogain®, has demonstrated a favorable safety profile and excellent biocompatibility in both experimental and clinical studies. EMD is non-cytotoxic and supports the attachment, proliferation, differentiation of periodontal ligament fibroblasts, osteoblasts, cementoblasts, and pulp cells [14]. Unlike many conventional materials, EMD promotes tissue regeneration without inducing significant inflammatory responses, thereby creating a favorable environment for wound healing and tissue repair [14,16]. Clinical studies have reported a low incidence of adverse reactions following EMD application. Because EMD is derived from porcine proteins, caution should be exercised in patients with known hypersensitivity to porcine-derived products. However, allergic reactions are extremely rare and have not been reported as a significant clinical concern in the literature [13,17].

Advantages [13,14,16,17]

- Excellent biocompatibility with hard and soft oral tissues.
- Non-cytotoxic and non-mutagenic.
- Minimal inflammatory or foreign-body reactions.
- Supports natural wound healing and tissue regeneration.
- Long-term clinical safety supported by extensive research.
- Low risk of allergic or immunological reactions.

Limitations

- Technique-sensitive procedure – Successful outcomes depend on meticulous technique of procedures Like pulpotomy and root surface preparation.
- Higher treatment cost – When compared with other materials used for pulpotomy and root surface preparation, Emdogain treatment charges are higher.

Future Prospects of Emdogain in Pediatric Dentistry:

Emdogain (Enamel Matrix Derivative) has promising future applications in Pediatric dentistry due to its regenerative potential. Ongoing research suggests that it might play significant role in regenerative endodontic procedures for immature permanent teeth, vital pulp therapy, apexogenesis, and the management of traumatic dental injuries. Its

ability to promote cell differentiation, tissue repair, angiogenesis, and periodontal regeneration may support the development of biologically based treatments aimed at preserving pulp vitality and enhancing root maturation. Furthermore, the integration of Emdogain with stem cell therapy, tissue engineering, and biomimetic scaffolds may expand its use in Pediatric regenerative dentistry. However, long-term clinical studies are still required to establish its efficacy and predictability in children.

CONCLUSION

Emdogain represents a valuable biologic agent in modern Pediatric Dentistry because of its capability for supporting periodontal and pulp tissue regeneration while promoting natural healing processes. Its application in regenerative endodontics, management of traumatic dental injuries, and preservation of pulp vitality highlights its potential to improve long-term outcomes in young patients. Although current evidence is encouraging broader clinical studies and long-term follow-up data are needed to establish standardized protocols and confirm its effectiveness across different Pediatric dental conditions. Emdogain is likely to play increasingly significant role in biologically driven treatment approaches aimed at preserving natural tissues and enhancing oral health in children.

ABSTRACT

Acute ischemic stroke requires rapid and accurate imaging for early diagnosis and management. Diffusion Weighted Imaging (DWI) at 3.0 Tesla MRI plays an important role in detecting early ischemic changes. To evaluate the significance of DWI in assessing acute ischemic stroke and correlate DWI findings with clinical severity and functional outcome. This retrospective observational study included 50 patients with acute ischemic stroke who underwent 3.0 Tesla MRI within 24 hours of symptom onset. MRI protocol included T1WI, T2WI, FLAIR, DWI, and ADC mapping. Clinical severity was assessed using NIHSS score and functional outcome using modified Rankin Scale (mRS). DWI detected lesions in 100% of cases and showed significantly higher sensitivity than conventional MRI sequences. DWI lesion volume showed strong positive correlation with NIHSS and mRS, while ADC values demonstrated strong negative correlation with stroke severity. DWI at 3.0 Tesla MRI is highly sensitive for early ischemic stroke detection and provides valuable prognostic information for clinical outcome assessment.

Keywords: Acute ischemic stroke, Diffusion Weighted Imaging, DWI, ADC, 3.0 Tesla MRI, NIHSS, mRS.

INTRODUCTION

Stroke is one of the leading causes of mortality and long-term neurological disability worldwide, with acute ischemic stroke accounting for nearly 80–85% of all cerebrovascular events. Rapid interruption of cerebral blood flow leads to irreversible neuronal injury within a short period; therefore, early diagnosis and prompt therapeutic intervention are essential for improving patient outcomes and reducing permanent disability. Conventional imaging techniques may fail to detect subtle ischemic changes during the hyperacute stage, limiting early clinical decision-making [1]. Magnetic Resonance Imaging (MRI) has become an important modality in the evaluation of acute ischemic stroke because of its excellent soft-tissue contrast and superior sensitivity for early brain parenchymal changes. Among various MRI techniques, Diffusion Weighted Imaging (DWI) has emerged as the most sensitive sequence for detecting acute cerebral ischemia. DWI identifies restricted diffusion caused by cytotoxic edema and can demonstrate ischemic lesions within minutes of symptom onset, much earlier than conventional MRI sequences such as T1-weighted imaging, T2-weighted imaging, and FLAIR imaging [2].

The development of 3.0 Tesla MRI systems has further enhanced the diagnostic value of DWI by providing improved signal-to-noise ratio, better spatial resolution, and superior lesion conspicuity. High-field MRI allows accurate visualization of small cortical, lacunar, and posterior circulation infarcts that may otherwise remain inconspicuous on routine imaging. In addition, quantitative diffusion parameters such as Apparent Diffusion Coefficient (ADC) values and DWI lesion volume have shown significant correlation with stroke severity and functional outcome, thereby contributing to prognostic assessment and treatment planning [3,4] Despite significant advances in neuroimaging, challenges still exist in differentiating hyperacute infarcts from stroke mimics and in establishing reliable imaging biomarkers for prognosis. Therefore, the present study was undertaken to evaluate the significance of Diffusion Weighted Imaging (DWI) in assessing brain stroke at 3.0 Tesla MRI and to correlate DWI findings with clinical severity and imaging characteristics in acute ischemic stroke patients [5,6].

Objectives of the Study

- To evaluate the diagnostic accuracy of DWI at 3.0T MRI in detecting acute ischemic stroke.
- To correlate DWI lesion volume and ADC values with clinical severity using NIHSS Stroke Scale.
- To study lesion characteristics across different stroke subtypes (lacunar, territorial, embolic).
- To compare DWI findings with conventional MRI sequence. (T1, T2, FLAIR)

MATERIALS AND METHODS

Study Design and Setting

This retrospective hospital-based observational study was conducted in the Department of Radio-diagnosis at Chhatrapati Shivaji Subharti Hospital from January 2025 to January 2026 using a United Imaging uMR780 3.0 Tesla MRI scanner.

Study Population

A total of 50 patients with clinically and radiologically diagnosed acute ischemic stroke who underwent brain MRI with Diffusion Weighted Imaging (DWI) within 24 hours of symptom onset were included in the study.

Inclusion Criteria

Patients aged 18–80 years who underwent 3.0 Tesla MRI brain with DWI within 24 hours of neurological symptom onset and had adequate imaging quality with complete clinical records were included.

Exclusion Criteria

Patients with brain tumors, recent head trauma, demyelinating diseases, incomplete imaging studies, or missing clinical data were excluded.

Imaging Protocol

MRI protocol included T1-weighted imaging, T2-weighted imaging, FLAIR, Diffusion Weighted Imaging (DWI) using b-values of 0 and 1000 s/mm², and Apparent Diffusion Coefficient (ADC) mapping using a 32-channel head and neck coil.

Image Analysis

DWI and ADC images were independently reviewed by two experienced radiologists blinded to clinical details. Lesion presence, location, infarct volume, diffusion characteristics, vascular territory involvement, and stroke subtype were evaluated.

Clinical Data Collection

Clinical data included age, sex, presenting symptoms, vascular risk factors, NIHSS score at presentation, hospital stay duration, and modified Rankin Scale (mRS) at discharge.

Outcome Parameters

The study assessed the sensitivity of DWI for early ischemic stroke detection and the correlation of DWI lesion characteristics with clinical severity and functional outcome.

Statistical Analysis

Data were analyzed using Microsoft Excel and SYSTAT version 13.2. Descriptive statistics, Chi-square test, Fisher's exact test, Student's t-test, and Mann–Whitney U-test were applied where appropriate. A p-value <0.05 was considered statistically significant.

RESULT

Statistical test applied: χ^2 test.

DWI detected acute ischemic lesions in all 50 patients (100.0%), whereas detection was lower with conventional MRI sequences. FLAIR identified lesions in 37 patients (74.0%), T2WI in 34 patients (68.0%), and T1WI in only 14 patients (28.0%). The difference in lesion detection between DWI and each conventional sequence was statistically significant ($p < 0.001$), indicating superior sensitivity of DWI for acute infarct detection in early stroke imaging.

Statistical test applied: χ^2 test.

Stroke subtype was significantly associated with NIHSS severity ($p<0.001$). Lacunar infarcts showed lower severity, while territorial and embolic infarcts were associated with higher NIHSS scores, indicating greater clinical severity at presentation.

Statistical test applied: χ^2 test.

DWI–FLAIR mismatch was present in 13 patients (26.0%), all of whom underwent MRI within ≤4.5 hours of symptom onset. In contrast, mismatch was absent in all patients imaged between 4.6–12 hours and 12.1–24 hours. The association between time from symptom onset and DWI–FLAIR mismatch was statistically significant ($p < 0.001$), indicating that DWI–FLAIR mismatch was mainly observed during the hyperacute phase of ischemic stroke.

The mean time from symptom onset to MRI was 9.98 ± 6.20 hours, with a median of 8.65 hours. The mean NIHSS score was 11.20 ± 6.04, indicating predominantly moderate clinical severity. Mean DWI lesion volume was 29.20 ± 24.80 mL, while mean ADC and minimum ADC values were 585.00 ± 75.30 and 390.00 ± 85.80 $\times 10^{-6}$ mm²/s, respectively. The mean hospital stay was 7.02 ± 3.19 days, and mean mRS at discharge was 2.78 ± 1.28.

The quantitative clinical and imaging parameters in the present study demonstrated a mean NIHSS score of 11.20 ± 6.04 and mean DWI lesion volume of 29.20 ± 24.80 mL, indicating predominantly moderate stroke severity. Mean ADC values were reduced in acute ischemic lesions, reflecting diffusion restriction associated with cytotoxic edema.

These findings are consistent with Dogariu et al. (2024)[7] and de Escalup et al. (2026)[1] who reported significant associations between infarct volume, ADC parameters, and neurological outcome. Similar observations by Farhan et al. (2025)[8] and Suzuki et al. (2023)[9] further support the prognostic relevance of diffusion-derived imaging biomarkers in acute ischemic stroke.

Mean ADC values decreased progressively with increasing NIHSS severity, indicating greater diffusion restriction and cytotoxic edema in severe strokes. Similar findings have been reported by de Escalup et al. (2026)[1], Nazari-Farsani et al. (2023)[10], and Nagaraja (2021)[6], supporting the prognostic value of ADC measurements in acute ischemic stroke. DWI demonstrated superior diagnostic performance compared with conventional MRI sequences, detecting acute ischemic lesions in 100% of patients, whereas FLAIR, T2WI, and T1WI showed lower detection rates. The differences were statistically significant ($p < 0.001$). These findings are consistent with previous studies by Farhan et al. (2025)[8] Arafat et al. (2023)[5] and Tedyanto et al. (2022)[11] which established DWI as the most sensitive MRI sequence for early ischemic stroke detection, particularly during the hyperacute phase. A significant association was also observed between time from symptom onset and DWI–FLAIR mismatch ($p < 0.001$), with mismatch present exclusively in patients imaged within ≤4.5 hours. This finding supports the established role of DWI–FLAIR mismatch as an imaging marker of hyperacute stroke and therapeutic eligibility, consistent with reports by Tedyanto et al. (2022)[11] and Yoshimoto et al. (2019)[10.] Collectively, the present study reinforces the diagnostic and prognostic significance of DWI at 3.0 Tesla MRI in acute ischemic stroke evaluation.

CONCLUSION

Diffusion Weighted Imaging (DWI) at 3.0 Tesla MRI demonstrated excellent diagnostic and prognostic value in the assessment of acute ischemic stroke. DWI showed superior sensitivity compared with conventional MRI sequences for early infarct detection and provided reliable evaluation of lesion burden and tissue ischemia. Quantitative diffusion parameters, particularly DWI lesion volume and ADC values, showed strong correlation with NIHSS score and functional outcome, emphasizing their role as important imaging biomarkers. The presence of DWI–FLAIR mismatch within the hyperacute window further highlighted its clinical relevance in early stroke triage and therapeutic decision-making. Therefore, DWI should remain an integral component of acute stroke imaging protocols.

ABSTRACT

In this paper, we introduce the concepts of normal interval valued intuitionistic Ω – fuzzy ternary semi–ring, Ω -fuzzy right ideal, anti-fuzzy right ideal, intuitionistic Ω -fuzzy right ideal, Ω -fuzzy right k-ideal, anti-fuzzy right k-ideal, intuitionistic Ω -fuzzy right k-ideal, Ω -fuzzy ideal, anti-fuzzy ideal, and intuitionistic Ω -fuzzy ideal in ternary semirings, and we investigate some of their basic properties. We define a regular ternary semi-ring using the Normal interval valued intuitionistic Ω -fuzzy right ideal. We introduce standard intuitionistic Ω -fuzzy ideals in ternary semi-rings. Hence, these notions are used to investigate some properties, theorems, and examples.

Keywords: Interval valued fuzzy set (IFS), Interval valued intuitionistic Ω – fuzzy right ideal.

INTRODUCTION

The speculation of fuzzy sets was introduced by L.A Zadeh [6], Attanassov et.al [1] [2] introduced the concepts of intuitionistic fuzzy sets and interval valued intuitionistic fuzzy sets and Dutta et.al [3] introduced the notation of on an interval valued fuzzy prime ideals of a semi–ring Krishnaswamy et.al [4] introduced the concept of interval valued intuitionistic fuzzy Bi-ideals in ternary semi ring in 2012, Lekkoksung [5] introduced the concept of intuitionistic Q–fuzzy K–ideals of semi ring.

PRELIMINARIES

Definition 2.1:
A non-empty set Γ together with a binary operation called, addition + and · a ternary multiplication, denoted by juxtaposition, is said to be a ternary semi-ring if (Γ; +) is a commutative semi-group satisfying the following conditions:
(i) $(\alpha\beta\delta)\theta\gamma = \alpha(\beta\delta\theta)\gamma = \alpha\beta(\delta\theta\gamma)$,
(ii) $(\alpha + \beta)\delta\theta = \alpha\delta d + \beta\delta\theta$,
(iii) $\alpha(\beta + \delta)\theta = \alpha\beta\theta + \alpha\delta\theta$ and
(iv) $\alpha\beta(\delta + \theta) = \alpha\beta\delta + \alpha\beta\ \delta$ for all $\alpha, \beta, \delta, \theta, \gamma \in \Gamma$.

Definition 2.2:
A non-empty interval-valued intuitionistic fuzzy subset Δ in a semi-ring Γ is called an interval-valued intuitionistic fuzzy ideal of Γ if it satisfies

i. $M_\Delta(\alpha + \beta) \geq \{M_\Delta(\alpha), M_\Delta(\beta)\}$
ii. $M_\Delta(\alpha\beta) \geq \{M_\Delta(\alpha), M_\Delta(\alpha)\}$
iii. $Q_\Delta(\alpha + \beta) \leq \{Q_\Delta(\alpha), Q(\beta)\}$
iv. $Q_\Delta(\alpha\beta) \leq \{Q_\Delta(\alpha), Q_\Delta(\beta)\}$ for all$\alpha, \beta \in \Gamma$.

Definition 2.3:
An interval-valued intuitionistic Ω −fuzzy subset $\Delta = (\tilde{M}_\Delta, \tilde{Q}_\Delta)in\Gamma$ is called an interval-valued intuitionistic Ω-fuzzy right ideal ofΓ if

i. $\tilde{M}_\Delta(\alpha + \beta, \omega) \geq min^i\{\tilde{M}_\Delta(\alpha, \omega), \tilde{M}_\Delta(\beta, \omega)\}$
ii. $\tilde{M}_\Delta(\alpha\beta\delta, \omega) \geq M(\alpha, \omega)$
$(\tilde{M}_\Delta(\alpha\beta\delta, \omega) \geq \tilde{M}_\Delta(\beta, \omega)$ or $\tilde{M}_\Delta(\alpha\beta\delta, \omega) \geq M(\delta, \omega))$
iii. $\tilde{Q}_\Delta(\alpha + \beta, \omega) \leq max^i\{\tilde{Q}_\Delta(\alpha, \omega), \tilde{Q}_\Delta(\beta, \omega)\}$
iv. $\tilde{Q}_\Delta(\alpha\beta\delta, \omega) \leq \tilde{Q}_\Delta(\alpha, \omega)$
$(\tilde{Q}_\Delta(\alpha\beta\delta, \omega) \leq \tilde{Q}_\Delta(\beta, \omega)$ or $\tilde{Q}_\Delta(\alpha\beta\delta, \omega) \leq \tilde{Q}_\Delta(\delta, \omega))$for all$\alpha, \beta, \delta \in \Gamma, \omega \in \Omega$.

Definition 2.4:
An interval-valued intuitionistic Ω-fuzzy subset $\Delta = (\tilde{M}_\Delta, \tilde{Q}_\Delta)$ is called an intuitionistic Ω-fuzzy ideal of Γ if it is interval-valued intuitionistic Ω- fuzzy right, interval-valued intuitionistic Ω-fuzzy lateral and interval-valued intuitionistic Ω-fuzzy left ideal of Γ.

Normal Interval Valued Intuitionistic Ω – Fuzzy Ideals
Definition 3.1:
An interval value intuitionistic Ω fuzzy right (left, lateral) ideal of $\Delta = (\tilde{M}_\Delta, \tilde{Q}_\Delta)$ of a ternary semi–ring Γ is said to be normal if $\Delta(0, \omega) = (\tilde{1}, \tilde{0})$ that means $\tilde{M}_\Delta(0, \omega) = \tilde{1}$, $\tilde{Q}_\Delta = (0, \omega) = \tilde{0}$. Denote by NIIFRI($\Gamma$), (NIIRLI($\Gamma$)), NIIFMI($\Gamma$) the set of all normal interval valued intuitionistic Ω – Fuzzy right (left, lateral) ideals of Γ. Note that NIIFRI(Γ), (NIIRLI(Γ)), NIIFMI(Γ) is a poset under set inclusion.

Theorem 3.1:
Given an interval valued intuitionistic Ω – fuzzy right (left lateral) ideal $\Delta = (\tilde{M}_\Delta, \tilde{Q}_\Delta)$ of a ternary semi-ring Γ. Let $\tilde{M}_\Delta(\alpha, \omega) = \tilde{M}_\Delta(\alpha, \omega) + \tilde{1} - \tilde{M}_\Delta(0, \omega)$and $\tilde{Q}_\Delta(\alpha, \omega) = \tilde{Q}_\Delta(\alpha, \omega) - \tilde{Q}_\Delta(0, \omega)$ for all $\alpha \in \Gamma, \omega \in \Omega$. Then $\Delta^+ = (\tilde{M}_{\Delta^+}, \tilde{Q}_{\Delta^+})$ is a normal – interval valued intuitionistic Ω – fuzzy right (left lateral) ideal containing $\Delta = (\tilde{M}_\Delta, \tilde{Q}_\Delta)$ of Γ.

Proof:
For all$\alpha, \beta, \delta \in \Gamma, \omega \in \Omega$
(i) $\tilde{M}_{\Delta^+}(\alpha + \beta, \omega) = \tilde{M}_\Delta(\alpha + \beta, \omega) + \tilde{1} - \tilde{M}_\Delta(0, \omega) \geq min^i\{\tilde{M}_\Delta(\alpha, \omega), \tilde{M}_\Delta(\beta, \omega)\} + \tilde{1} - \tilde{M}_\Delta(0, \omega) = min^i\{\tilde{M}_\Delta(\alpha, \omega) + \tilde{1} - \tilde{M}_\Delta(0, \omega), \tilde{M}_\Delta(\beta, \omega) + \tilde{1} - \tilde{M}_\Delta(0, \omega)\} = min^i\{\tilde{M}_{\Delta^+}(\alpha, \omega) + \tilde{M}_{\Delta^+}(\beta, \omega)\}$

(ii) $\tilde{M}_{\Delta^+}(\alpha\beta\delta,\omega) = \tilde{M}_{\Delta}(\alpha\beta\delta,\omega) + \tilde{1} - \tilde{M}_{\Delta}(0,\omega) \geq \tilde{M}_{\Delta}(\alpha,\omega) + \tilde{1} - \tilde{M}_{\Delta}(0,\omega) = \tilde{M}_{\Delta^+}(\alpha,\omega)$
(iii)
$\tilde{Q}_{\Delta^+}(\alpha+\beta,\omega) = \tilde{Q}_{\Delta}(\alpha+\beta,\omega) - \tilde{Q}_{\Delta}(0,\omega) \leq max^i\{\tilde{Q}_{\Delta}(\alpha,\omega), \tilde{Q}_{\Delta}(\beta,\omega)\} - \tilde{Q}_{\Delta}(0,\omega) =$
$max^i\{\tilde{Q}_{\Delta}(\alpha,\omega) - \tilde{Q}_{\Delta}(0,\omega), \tilde{Q}_{\Delta}(\beta,\omega) - \tilde{Q}_{\Delta}(0,\omega)\} = max^i\{\tilde{Q}_{\Delta^+}(\alpha,\omega) + \tilde{Q}_{\Delta^+}(\beta,\omega)\}$
(iv)) $\tilde{Q}_{\Delta^+}(\alpha\beta\delta,\omega) = Q(\alpha\beta\delta,\omega) - \tilde{Q}_{\Delta}(0,\omega) \leq \tilde{Q}_{\Delta}(\alpha,\omega) - \tilde{Q}_{\Delta}(0,\omega) = \tilde{Q}_{\Delta^+}(\alpha,\omega)$
Hence Δ^+ is an interval valued intuitionistic Ω – fuzzy ideal of Γ.
Again we have, $\tilde{M}_{\Delta^+}(0,\omega) = \tilde{M}_{\Delta}(0,\omega) + \tilde{1} - \tilde{M}_{\Delta}(0,\omega) = \tilde{1} \leq \tilde{M}_{\Delta^+}(\alpha,\omega) - \tilde{M}_{\Delta^+}(0,\omega) = \tilde{M}_{\Delta^+}(\alpha,\omega)$ and similarly $\tilde{Q}_{\Delta^+}(0,\omega) = \tilde{Q}_{\Delta}(0,\omega) - \tilde{Q}_{\Delta}(0,\omega) = \tilde{0}$
Hence Δ^+ is an interval valued intuitionistic Ω – fuzzy right ideal of Γ and by definition $\Delta \subseteq \Delta^+$

Corollary 3.3:
Let $\Delta and \Delta^+$ be as in the theorem 3.2. Δ is a normal interval valued intuitionistic Ω – fuzzy right ideal of Γ if and only if $\Delta = \Delta^+$.

Remark 3.4
If $\Delta = (\tilde{M}_{\Delta}, \tilde{Q}_{\Delta})$ is an interval valued intuitionistic Ω – fuzzy right (left lateral) ideal of Γ, then $(\Delta^+)^+ = \Delta^+$. In particular, if Δ is normal, then $(\Delta^+)^+ = \Delta^+ = \Delta$.

Theorem 3.5
Let $\Delta = (\tilde{M}_{\Delta}, \tilde{Q}_{\Delta})$ is an interval valued intuitionistic Ω – fuzzy right (left lateral) ideal of a ternary semi-ring Γ and let $\Psi: D[0,1] \to D[0,1]$ be an increasing function. Then an IIRFS $\Delta_\Psi = ((\tilde{M}_{\Delta})\Psi, (\tilde{Q}_{\Delta})\Psi)$, where $(\tilde{M}_{\Delta})\Psi(\alpha,\omega) = \Psi(\tilde{M}_{\Delta}(\alpha,\omega))$ and $(\tilde{Q}_{\Delta})\Psi(\alpha,\omega) = \Psi(\tilde{Q}_{\Delta}(\alpha,\omega))$ for all $\alpha \in \Gamma, \omega \in \Omega$ is an interval valued intuitionistic Ω – fuzzy right (left, lateral) ideal of Γ. moreover, if $\Psi\left(\tilde{M}_{\Delta}(0,\omega)\right) = \tilde{1}$ and $\Psi\left(\tilde{Q}_{\Delta}(0,\omega)\right) = \tilde{0}$, then A_Ψ is normal.

Proof:
Let$\alpha, \beta, \delta \in \Gamma, \omega \in \Omega$
(i) $(\tilde{M}_{\Delta})\Psi(\alpha+\beta,\omega) = \Psi(\tilde{M}_{\Delta}(\alpha+\beta,\omega)) \geq \Psi(min^i\{\tilde{M}_{\Delta}(\alpha,\omega), \tilde{M}_{\Delta}(\beta,\omega)\}) = min^i\{\Psi\left(\tilde{M}_{\Delta}(\alpha,\omega)\right), \Psi\left(\tilde{M}_{\Delta}(\beta,\omega)\right)\} =$
$min^i\{(\tilde{M}_{\Delta})\Psi(\alpha,\omega), (\tilde{M}_{\Delta})\Psi(\beta,\omega)\}$
(ii)$(\tilde{M}_{\Delta})\Psi(\alpha\beta\delta,\omega) = \Psi(\tilde{M}_{\Delta}(\alpha\beta\delta,\omega)) \geq \Psi\left(\tilde{M}_{\Delta}(\alpha,\omega)\right) = (\tilde{M}_{\Delta})\Psi(\alpha,\omega)$
(iii) $(\tilde{Q}_{\Delta})\Psi(\alpha+\beta,\omega) = \Psi(\tilde{Q}_{\Delta}(\alpha+\beta,\omega)) \leq \Psi(max^i\{\tilde{Q}_{\Delta}(\alpha,\omega), \tilde{Q}_{\Delta}(\beta,\omega)\}) = max^i\{\Psi\left(\tilde{Q}_{\Delta}(\alpha,\omega)\right), \Psi\left(\tilde{Q}_{\Delta}(\beta,\omega)\right)\} =$
$max^i\{(\tilde{Q}_{\Delta})\Psi(\alpha,\omega), (\tilde{Q}_{\Delta})\Psi(\beta,\omega)\}$
(iv)$(\tilde{Q}_{\Delta})\Psi(\alpha\beta\delta,\omega) = \Psi(\tilde{Q}_{\Delta}(\alpha\beta\delta,\omega)) \leq \Psi\left(\tilde{Q}_{\Delta}(\alpha,\omega)\right) = (\tilde{Q}_{\Delta})\Psi(\alpha,\omega)$
Hence Δ_Ψ is an interval valued intuitionistic Ω – fuzzy right ideal of Γ.
If $\Psi(\tilde{M}_{\Delta}(0,\omega) = \tilde{1}, \Psi(\tilde{Q}_{\Delta}(0,\omega) = \tilde{0}$ then $(\tilde{M}_{\Delta})\Psi(0,\omega) = \tilde{1} and (\tilde{Q}_{\Delta})\Psi(0,\omega) = \tilde{0}$and Hence $\Delta_\Psi = ((\tilde{M}_{\Delta})\Psi, (\tilde{Q}_{\Delta})\Psi)$ is a normal interval valued intuitionistic Ω – fuzzy right ideal of Γ.

Definition 3.6:
An interval valued intuitionistic Ω – fuzzy right (left lateral) ideal $\Delta = (\tilde{M}_{\Delta}, \tilde{Q}_{\Delta})$ of a ternary semi-ring Γ is said to be an interval valued intuitionistic Ω – fuzzy maximal if it satisfies (i) Δ is non – constant (ii) is a maximal element of NIIRFI(Γ), where NIIRFI(Γ) denote the set of all normal interval valued intuitionistic Ω – fuzzy ideal of Γ.

Example 3.7:
Consider the ternary semiring$\Gamma = Z^+$ the set of all non-positive integers with the usual addition and ternary multiplication. Let the interval valued Ω – fuzzy subset $\tilde{M}_{\Delta}$ and $\tilde{Q}_{\Delta}$ of Γ be defined as

$$\tilde{M}_{\Delta} = \{\tilde{1}, if \alpha \in (-2)\tilde{0}, otherwise$$

and

$$\tilde{Q}_{\Delta} = \{\tilde{0}, if \alpha \in (-2)\tilde{1}, otherwise$$

Then $\Delta = (\tilde{M}_\Delta, \tilde{Q}_\Delta)$ is an interval valued intuitionistic Ω – fuzzy maximal ideal of Γ.

Theorem 3.8:
Let $\Delta = (\tilde{M}_\Delta, \tilde{Q}_\Delta)$ (NIIRFI(Γ)) be non – constant such that it is maximal in the poset of NIIRFI(Γ) under the inclusion then both $\tilde{M}_\Delta and \tilde{Q}_\Delta$ takes only the values $(\tilde{1}, \tilde{0})$ and $(\tilde{0}, \tilde{1})$ respectively.

Proof:
Since Δ is normal interval valued intuitionistic Ω – fuzzy right ideal, so $\Delta(0, \omega) = (\tilde{1}, \tilde{0})$ and let $\alpha_0 (\neq 0) \in \Gamma$ be arbitrary with $\tilde{M}_\Delta(\alpha_0, \omega) \neq \tilde{1}$.

We claim that $\tilde{M}_\Delta(\alpha_0, \omega) = \tilde{0}$. If not then there exists an element $\gamma \in \Gamma$ such that $0 < \tilde{M}_\Delta(\gamma, \omega) < \tilde{1}$. Let $\Delta_\gamma = (\widetilde{\lambda_\Delta}, \widetilde{\mu_\Delta})$ be an interval valued intuitionistic Ω – fuzzy subset of Γ defined by $\widetilde{\lambda_\Delta}(\alpha, \omega) = \frac{1}{2}[\tilde{M}_\Delta(\alpha, \omega) + \tilde{M}_\Delta(\gamma, \omega)]$ and $\widetilde{\mu_\Delta}(\alpha, \omega) = \frac{1}{2}[\tilde{Q}_\Delta(\alpha, \omega) + \tilde{Q}_\Delta(\gamma, \omega)]$.

Clearly Δ_γ is well defined now, $\widetilde{\lambda_\Delta}(0, \omega) = \frac{1}{2}\left[\tilde{M}_\Delta(0, \omega) + \tilde{M}_\Delta(0, \omega)\right] \geq \frac{1}{2}\left[\tilde{M}_\Delta(\alpha, \omega) + \tilde{M}_\Delta(\alpha, \omega)\right] = \widetilde{\lambda_\Delta}(0, \omega) + \widetilde{\mu_\Delta}(\alpha, \omega) = \frac{1}{2}\left[\tilde{Q}_\Delta(0, \omega) + \tilde{Q}_\Delta(0, \omega)\right] \leq \frac{1}{2}\left[\tilde{Q}_\Delta(\alpha, \omega) + \tilde{Q}_\Delta(\alpha, \omega)\right] = \widetilde{\mu_\Delta}(\alpha, \omega)$ for $\alpha \in \Gamma$.

Again $\alpha, \beta, \delta \in \Gamma, \omega \in \Omega$

(i) $\tilde{\lambda}_\Delta(\alpha + \beta, \omega) = \frac{1}{2}[\tilde{M}_\Delta(\alpha + \beta, \omega) + \tilde{M}_\Delta(\gamma, \omega)] \geq \frac{1}{2}[min^i\{\tilde{M}_\Delta(\alpha, \omega), \tilde{M}_\Delta(\beta, \omega)\} + \tilde{M}_\Delta(\gamma, \omega)] = min^i\{\frac{1}{2}[\tilde{M}_\Delta(\alpha, \omega) + \tilde{M}_\Delta(\gamma, \omega)], \frac{1}{2}[\tilde{M}_\Delta(\beta, \omega) + \tilde{M}_\Delta(\gamma, \omega)]\} = min^i\{\tilde{\lambda}_\Delta(\alpha, \omega), \tilde{\lambda}_\Delta(\beta, \omega)\}$

(ii) $\tilde{\lambda}_\Delta(\alpha\beta\delta, \omega) = \frac{1}{2}[\tilde{M}_\Delta(\alpha\beta\delta, \omega) + \tilde{M}_\Delta(\gamma, \omega)] \geq \frac{1}{2}\left[\{\tilde{M}_\Delta(\alpha, \omega) + \tilde{M}_\Delta(\gamma, \omega)\right] = \tilde{\lambda}_\Delta(\alpha, \omega)$

(iii) $\tilde{\mu}_\Delta(\alpha + \beta, \omega) = \frac{1}{2}[\tilde{Q}_\Delta(\alpha + \beta, \omega) + \tilde{Q}_\Delta(\gamma, \omega)] \leq \frac{1}{2}[max^i\{\tilde{Q}_\Delta(\alpha, \omega), \tilde{Q}_\Delta(\beta, \omega)\} + \tilde{Q}_\Delta(\gamma, \omega)] = max^i\{\frac{1}{2}[\tilde{Q}_\Delta(\alpha, \omega) + \tilde{Q}_\Delta(\gamma, \omega)], \frac{1}{2}[\tilde{Q}_\Delta(\beta, \omega) + \tilde{Q}_\Delta(\gamma, \omega)]\} = max^i\{\tilde{\mu}_\Delta(\alpha, \omega), \tilde{\mu}_\Delta(\beta, \omega)\}$

(iv) $\tilde{\mu}_\Delta(\alpha\beta\delta, \omega) = \frac{1}{2}[\tilde{Q}_\Delta(\alpha\beta\delta, \omega) + \tilde{Q}_\Delta(\gamma, \omega)] \leq \frac{1}{2}\left[\{\tilde{Q}_\Delta(\alpha, \omega) + \tilde{Q}_\Delta(\gamma, \omega)\right] = \tilde{\mu}_\Delta(\alpha, \omega)$

Hence Δ is an interval valued intuitionistic Ω – fuzzy ideal of Γ.

Define $\Delta_C^+ = \left(\widetilde{\lambda_{\Delta^+}}, \widetilde{\mu_{\Delta^+}}\right)$ then by theorem 3.2, Δ_C^+ is a normal interval valued intuitionistic Ω – fuzzy right ideal of Γ, where $\widetilde{\lambda_{\Delta^+}}(\alpha, \omega) = \widetilde{\lambda_{\Delta^+}}(\alpha, \omega) + \tilde{1} - \widetilde{\lambda_{\Delta^+}}(0, \omega) = \frac{1}{2}[\tilde{M}_\Delta(\alpha, \omega) + \tilde{M}_\Delta(\gamma, \omega)] + \tilde{1} - \frac{1}{2}[\tilde{M}_\Delta(0, \omega) + \tilde{M}_\Delta(0, \omega)] = \frac{1}{2}[\tilde{1} + \tilde{M}_\Delta(\alpha, \omega)]$ and $\widetilde{\mu_{\Delta^+}}(\alpha, \omega) = \widetilde{\mu_{\Delta^+}}(\alpha, \omega) - \widetilde{\mu_{\Delta^+}}(0, \omega) = \frac{1}{2}[\tilde{Q}_\Delta(\alpha, \omega) + \tilde{Q}_\Delta(\gamma, \omega)] - \frac{1}{2}[\tilde{Q}_\Delta(0, \omega) + \tilde{Q}_\Delta(0, \omega)] = \frac{1}{2}[\tilde{Q}_\Delta(\alpha, \omega)]$

Clearly $\Delta \subseteq \Delta_C^+$. Since $\widetilde{\lambda_{\Delta^+}}(\alpha, \omega) = \frac{1}{2}\left[\tilde{1} + \tilde{M}_\Delta(\alpha, \omega)\right] > \tilde{M}_\Delta(\alpha, \omega)$ and $\widetilde{\mu_{\Delta^+}}(0, \omega) = \frac{1}{2}\left[\tilde{Q}_\Delta(\alpha, \omega)\right] < \tilde{Q}_\Delta(\alpha, \omega)$, Δ is a proper subset of Δ_C^+. Again since $\widetilde{\lambda_{\Delta^+}}(\gamma, \omega) = \frac{1}{2}\left[\tilde{1} + \tilde{M}_\Delta(\gamma, \omega)\right] < \tilde{1} = \tilde{M}_\Delta(0, \omega)$. Hence Δ_γ^+ is non constant and Δ is not a maximal element of NIIRFRI(Γ). This is contradiction. Therefore $\tilde{M}_\Delta$ takes only two values $\tilde{1} and \tilde{0}$ and $\tilde{Q}_\Delta$ takes only two values $\tilde{0} and \tilde{1}$. This complete the proofs.

ABSTRACT

This research analyzes the dynamic communications between a supervisor and a supervisee during the fieldwork practicum of Master of Social Work students from Chennai, Tamil Nadu. Its core objectives are to analyze the students' perspectives of these interactions and their influence on the learning process. The research particularly focuses on how each student's unique background affects their approach toward instruction while aiming to enhance the overall experience for learners, placing stronger focus on adaptive strategies aimed at different levels, thus broadening the instructional design enhancing future social work practitioners throughout Tamil Nadu. The study employs Independent sample 't' statistical test of survey with 144 students to understand their perspectives towards supervision.The results reveal that constructive supervision significantly enhances independent analysis and professional development. The information was obtained through questionnaires which demonstrated both positive and negative aspects of the supervisory roles. Students also reported that supervision can be improved through collaboration between the institution and the agency.The information was obtained through questionnaires which demonstrated both positive and negative aspects of the supervisory roles. Crystal clear observation from the result is how quality supervision impacts students' Professional skill development. A revised fieldwork supervision framework will enhance the standard of supervision in future.

Keywords: Social Work, Field Work Practicum, supervision, supervisor-supervisee interaction, master of social work students.

INTRODUCTION

Background of the study:

Field education is often perceived as the most important part of social work training, since it allows students to merge theoretical learning from classes with hands-on experience. A fieldwork placement comes with support in the form of supervision, which ensures that the proper frameworks are provided to help this amalgamation happen. Thus, the supervisor–supervisee relationship becomes critical toward illuminating and shaping the student's learning journey, professional identity, and self-efficacy within myriad social work settings (Bogo, 2015). Supervision fulfills a social work practice supervision of three core functions: administrative function; educational function; and supportive function (Kadushin & Harkness, 2014). Here the administrative function provides knowledge of accountability and compliance with organizational guidelines including requisite policies from government bodies dedicated to industry welfare. Focusing on their teaching goals, the educational function deals with application and integration of theory into actual practice. Considerations around looking after the well-being of junior staff members falls under The Supportive Function. Attaining proper outcomes demands that all these roles be balanced by supervisors who must also remain adjustable to the developmental stages of their supervisees (Tsui, 2005).

Quality of Supervisory Relationship:

The effectiveness of fieldwork education is significantly influenced by the quality of the supervisory relationship (Saju, 2014).A strong, positive, and collaborative alliance between supervisor and supervisee, characterized by open communication, trust, empathy, and constructive feedback, creates a secure and supportive learning environment (Zuchowski, 2015).This environment is crucial for fostering critical thinking, promoting self-awareness, and encouraging reflective practice among students (Sandile, Ntombifikile, Mbongeni, 2024)Conversely, a lack of engagement, inconsistent feedback, or an overly authoritative supervisory style can lead to student dissatisfaction, diminished learning motivation, and impede professional development (Bennett & Deal, 2009).

Reflective Practice and Professional Identity:

Reflective practice is a cornerstone of social work education, and supervision serves as a primary vehicle for cultivating this essential competency. (Schön, 1983) says, supervisors who foster reflection enable students to critically analyze their actions, evaluate the impact of their interventions, and develop a nuanced understanding of client needs and social work values.According to (Knight, 2001), this reflective engagement is vital for professional identity formation, helping students learn from experience and grow into capable and ethical practitioners.

Cultural and Contextual Considerations:

Much of the literature on supervision has emerged from Western contexts, which may not fully capture the unique challenges and cultural dynamics present in countries like India. In the Indian context, hierarchical structures in education and organizational settings can influence supervisory dynamics, sometimes creating power imbalances that hinder open dialogue and student agency (Rai, 2012). Additionally, resource limitations, inconsistent supervisor training, and lack of institutional support can further complicate the supervision process in fieldwork settings (Desai, 2006).

Studies from the Indian Context:

While Indian literature on fieldwork supervision is relatively sparse, some studies have begun to highlight region-specific issues. Research by (Gokhale, 2014) and (Samuel, 2018) suggests that many MSW students in India face challenges such as limited engagement from supervisors, inadequate feedback, and a lack of structured reflection sessions. These studies emphasize the need for supervisor training, standardized supervision protocols, and greater institutional oversight to ensure quality field education. Moreover, the diversity of student backgrounds—linguistic, socio-economic, and educational—necessitates a more tailored, student-centered approach to supervision.

Need for Student-Centered Perspective:

Despite these emerging insights, there remains a critical gap in understanding how students themselves perceive and experience the supervisor–supervisee relationship. While supervisors' perspectives are occasionally documented, students' voices are often underrepresented in scholarly discourse (Bennett, 2009). This imbalance restricts the development of supervision practices that are responsive to actual student needs. Listening to students' experiences offers valuable insights into the effectiveness of supervision, highlights areas for improvement, and strengthens the pedagogical integrity of social work field education (Wayne, Bogo, & Raskin, 2010).

Aim and Objective of the Study:

The main aim of the study is to examine the perspective of students on supervisor-supervisee interaction in fieldwork practicum among Master of Social Work students in Social Work Education offered by colleges in Chennai City of Tamil Nadu state

The objectives of the study are

- To describe the socio-demographic characteristics and field work practicum among master of Social Work students.
- To measure the perception of students on supervisor-supervisee interaction in fieldwork practicum among Master of Social Work students
- To identify factors that contribute to effective supervision and offer insights to enhance the supervisory process in social work education.

METHODS AND MATERIALS

The study employs a descriptive quantitative design to collect data from social work students regarding their perspectives on supervisor-supervisee interaction in fieldwork practicum .

Participants:

6 Institutions offering social work fromchennai were selected 144 social work students were recruited using simple random sampling using the lottery method. The majority of the students were aged between 21-25 years (96.5%). Less than half of the students (20.8%) have Bachelor's in social work as qualification. More than half of the Social work students were females (55.6%). The majority of agency supervisors had experience of 0-10 years (81.9%) students were females (55.6%). Nearly half of the social work students have chosen Human Resource as their specialization.

Measurements:

Sociodemographic questionnaire:

The sociodemographic questionnaire consisted of 19 questions for gathering information about the participant's background and demographics. Questions were related to personal characteristics such as gender, age, marital status, place of residence, educational qualification, specialization in the course, type of department, experience of both agency and faculty supervisor.

Questionnaire on Supervisor-Doctoral Student Interaction (QSDI):

The standardized scale used was "Questionnaire on Supervisor-Doctoral Student Interaction (QSDI)" by Mainhard et al. (n.d) in the Netherlands, with 41 items. The items are designed based on Likert's five-point scale (never, rarely, sometimes, mostly, and always), and the score of each item ranges from 1 to 5. The questionnaire has eight subscales which are, Helping/Friendly, Admonishing, Uncertain, Strict, Understanding, Dissatisfied, Leadership, Responsibility and tested Cronbach's alpha.

Procedure:
The study was approved by all the institutional heads before data collection. Informed consent was obtained from every participant, and the questionnaire was distributed to the students, which took approximately 10 min to complete,

Data analysis:
Data analysis involves descriptive statistics, *t*-tests conducted through SPSS software.

RESULTS

The demographic data shows that the vast majority of respondents were young adults aged 21–25 (96.5%), with only a small number (3.5%) in the 26–30 age group. A slightly higher proportion of students were female (55.6%) compared to male (44.4%). Most participants were unmarried (94.4%), and a majority resided in urban areas (68.1%), followed by rural (21.5%) and semi-urban (10.4%) locations, reflecting a largely city-based student population with some rural representation. In terms of academic background, the largest group held an undergraduate degree in Arts (66.7%), while 20.8% had prior training in social work through a Bachelor of Social Work (B.S.W), and 12.5% came from science disciplines. According to the results students identified diverse learning outcomes from their fieldwork. In terms of academic background, the largest group held an undergraduate degree in Arts (66.7 percent), while (20.8 percent) had prior training in social work through a Bachelor of Social Work (B.S.W), and (12.5 perfect) came from science disciplines (Table 1). This indicates a diverse academic foundation, though predominantly rooted in the humanities. Most common was the development of professional competency skills (26.4 percent), followed by specialization-based learning and personal skill development (20.1 percent) each. Fewer students reported gains in practical skills (12.5 percent), ethical behavior (8.3 percent), and administrative competencies (6.9 percent). Notably, only (5.6 percent) emphasized active field participation, suggesting limited hands-on engagement for some. Less than half of the students learn professional competency skills through field work (Table 2) regarding the students' perception of supervision improvement. The data also reveals that (55.6 percent) of students were supervised by professionals with a formal social work background, while (44.4 percent) were guided by individuals from non-social work disciplines, particularly within field agencies. This discrepancy suggests a lack of uniformity in professional alignment, which may impact the relevance and quality of field instruction (Table 3). More than half (55.6 percent) of supervisors are trained social workers while there can be considerable concerns over the qualification of the remaining (44.4 percent). Considerable (20.8 percent) of the students reported that no changes are needed in supervision, followed by meager (16.7 percent) of the students who reported that supervision can be improved through collaboration between the institution and the agency (Table 4). While analyzing the satisfaction in fieldwork supervision and satisfaction in learning, it was noticed that more than nearly three-quarters of the students (75%) were either dissatisfied or very dissatisfied with the quality of fieldwork supervision (Table 5). While analyzing the students' perception of various dimensions of faculty and agency, supervisor-supervisee interaction, it was observed that the majority of the students reported that the faculty and agency supervisor displays a medium level of helping/ friendly, admonishing, uncertain, strict, understanding, and dissatisfied. The students also expressed that the majority of the faculty and agency supervisors fall in line with a low level of leadership and students' responsibility/freedom (Table 6). Conversely, lack of engagement, rigid hierarchies, and inadequate support were seen to hinder the learning process and cause dissatisfaction among students.

DISCUSSION

The data highlights significant issues with fieldwork supervision, despite moderately positive learning experiences. There's a clear disconnect between institutional expectations and supervision quality, with limited perceived support or empowerment. Improvements are needed in areas such as Supervisor training and competency, Field-agency collaboration, Student-centered approaches in supervision. There is also a significant gap in supervisory support, which may affect students' motivation, skill development, and integration of classroom knowledge into practice.

While supervision is largely being provided by trained individuals, there are variations in both background and depth of experience—especially within agencies. Enhancing supervisory training, particularly for non-social work professionals and less experienced supervisors, could greatly improve the coherence and impact of field education.The findings provide a strong basis for recommending structured training for supervisors, better placement planning, and robust monitoring mechanisms.

RECOMMENDATIONS

- Fieldwork curriculum review might further highlight supervisor-supervisee relations focusing on reflective practice, ethics literacy, and moral performance capability within professional boundaries.
- Ensuring alignment between students' specializations and their associated fieldwork assignments enhances purposeful learning. Integration of understudied areas such as documentation systems, administrative processes, collaboration across disciplines, and interprofessional teamwork may be included.
- Advocacy concerning policy inclusion regarding the agency supervisory position's minimum credentials and qualifying criteria may prove beneficial.
- There is room for improvement related to developing a set of expectations describing assigned tasks articulated within a policy framework pertaining specifically to the role of field supervisors. Periodic assessment of students out on rotations could foster responsibility alongside quality control.
- Joint review meetings could be conducted to merge theoretical academic frameworks with practical field-based realities for aligned supervision and coherent learning outcomes.
- Holding regular capacity-building workshops would be useful for both agency and faculty supervisors in the areas of mentorship, ethics, student engagement, and feedback systems. It might also be beneficial to create an orientation or certification module tailored for agency supervisors who lack formal social work training.
- Redesigning the position of supervisors granting pedagogical status with respect to teaching 'Supervision' by providing scheduled time allowances along with honorariums and academic credit may attract committed practitioners willing to supervise them regularly.
- The model of triadic supervision, integrating student, field supervisor, and faculty supervisor, may assist in narrowing the integration gap between theoretical and practical work by fulfilling academic requirements more holistically.
- Encouraging personalized approaches to supervision that take into account students' learning preferences, past experiences, emotional needs for support into their prior trajectories may prove beneficial as well. Also suggested are peer-support groups or reflective circles aimed at exchange of experiences to reduce social isolation and mitigate dissatisfaction.

CONCLUSION

There are few challenges found in the Social work field work supervision in Indian context particularly. But the extant research strongly avowed the value of quality supervision. Communication, empathy, timely feedback, and reflective dialogue substantially enhances students' learning, confidence, and professional identity formation through strong and competent supervision. The finding also draws attention to developing a supervision model that can be even more standardized, student centered and culturally sensitive within Social work education in India. As relevant studies also suggest professional supervisor-supervisee interaction paves way in quality and competent fieldwork practicum model for Master in Social Work students in Tamil Nadu. The research paper also suggests that more future studies to better understand supervision and how it can be improved to develop a better professionally competent social worker can be conducted among a large population. Strengthening the supervisory framework through institutional support, capacity-building for supervisors, and feedback mechanisms can lead to a more enriching and transformative educational experience for future social workers.

ACKNOWLEDGEMENT

The researchers extend sincere gratitude to all the social work students who participated in this study and shared their experiences. Special thanks are due to the heads of institutions and faculty members who facilitated data collection.

Ethical approval and informed consent statement
Ethical approval from all the institution heads and Informed consent was obtained from all participants prior to data collection. Participants were assured of confidentiality, anonymity, and their right to withdraw at any stage without any consequences.

Declaration of conflicting interest:
The author declares that there are no conflicts of interest with respect to the authorship and/or publication of this study.

Funding:
This research received no specific grant from any funding agency or organization.

ABSTRACT

Osteoarthritis is one of the most common musculoskeletal disorders; among this, knee osteoarthritis is the most common form. The osteoarthritis causes various anatomical and physiological changes in joint tissues, such as cartilage degradation, synovial inflammation, subchondral bone involvement and the development of osteophytes. Osteoarthritis is recognized as the most common joint disorder, and from 1990 to 2019, the global prevalence of KOA increased by 48%. The study aims to evaluate the effects of an integrated Proprioceptive Neuromuscular Facilitation (PNF) program on pain, functional ability and quality of life in patients with knee osteoarthritis. Two-group pre-test- post-test RCT Patients will be recruited based on selection criteria. Patients will be recruited and randomly allocated into either the experimental group or the control group. The experimental group will receive an integrated PNF program, while the control group will receive conventional physiotherapy management for 4 weeks (3 sessions/week). Outcome measures including The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), the Visual Analogue Scale (VAS), Universal Goniometer and the 36-Item Short Form Health Survey (SF-36), will be assessed at baseline and after 4 weeks of intervention. Data will

be analysed using the Statistical Package for Social Sciences (SPSS) software. Shapiro-Wilk test will be used to establish the normality of the data. If data is found to be normally distributed it will be presented as Mean ± SD and paired t-test will be used for within the group analysis and unpaired t-test will be used for between the group analysis. If data is found to be not normally distributed it will be presented as Median (Interquartile range) and Wilcoxon rank test will be used for within the group analysis and Mann Whitney U test will be used for between the group analysis.

Keywords: Proprioceptive Neuromuscular Facilitation; Knee Osteoarthritis; WOMAC; Rehabilitation; Quality of Life.

INTRODUCTION

Knee osteoarthritis (KOA) is one of the most common chronic degenerative musculoskeletal disorders affecting older people worldwide.[1] It is characterized by progressive degeneration of articular cartilage, sub-chondral bone re-modeling, osteophyte formation, joint space narrowing, and synovial inflammation, all of which may cause pain, stiffness, reduced range of motion, and functional limitation.[2]The Global Burden of Disease study, the prevalence of knee osteoarthritis has increased significantly over recent decades due to population ageing, obesity, sedentary lifestyle, and increasing life expectancy.[3] In 2020 approximately 654 million individuals worldwide were reported to be affected by knee osteoarthritis, making it a major contributor to disability and reduced quality of life among older adults.[4]In addition to structural joint degeneration, patients with KOA frequently experience impaired balance, reduced muscle strength, proprioceptive deficits, and altered movement patterns that interfere with activities of daily living such as walking, stair climbing, and sit-to-stand activities.[5] Conventional physiotherapy management for knee osteoarthritis commonly includes thermotherapy, stretching exercises, strengthening exercises, aerobic conditioning, and functional rehabilitation programs aim to reduce pain and improve mobility of the joint.[5,6] Although these interventions are effective in providing symptomatic relief, persistent deficits in proprioception, neuromuscular control, flexibility, and dynamic joint stability may continue to affect physical function and quality of life in many individuals with KOA.[5]Therefore, rehabilitation approaches that simultaneously address flexibility, neuromuscular activation, proprioception, and coordinated movement patterns may give significant clinical benefits in individuals with knee osteoarthritis.

Proprioceptive Neuromuscular Facilitation (PNF) is an advanced therapeutic approach developed to improve neuromuscular function through specific movement patterns and facilitation techniques.[7,8] PNF techniques are widely used in musculoskeletal rehabilitation to enhance flexibility, muscular coordination, proprioception, joint stability, and functional performance.[7]Previous studies have demonstrated that PNF-based interventions can improve pain, balance, range of motion, and physical function in individuals with knee osteoarthritis.[4,5,9,10] PNF stretching techniques are considered particularly effective because they facilitate both muscular relaxation and neuromuscular activation, thereby improving movement efficiency and joint stability.[8] Among various PNF techniques, the Hold–Relax technique is commonly used to reduce muscle tightness and improve flexibility using autogenic inhibition and muscle relaxation mechanisms.[7]This technique consists of an isometric contraction of the target muscle followed by passive stretching, which increases the muscular extensibility and improves joint mobility.[11] Hold-Relax stretching has been shown to improve hamstring flexibility, pain relief, and functional mobility in patients with knee osteoarthritis.[10,12] Hamstring tightness contributes to altered knee biomechanics and increased joint stress, improving muscle flexibility may help to reduce pain and improve functional performance in people with KOA.[1] Another important PNF technique is Combination of Isotonics, which consists of concentric, eccentric, and isometric muscle contractions performed sequentially without rest.[13] This technique is designed to improve muscle activation, neuromuscular coordination, dynamic stability, and controlled movement patterns.[13,14] Combination of Isotonics may help improve functional movement and joint stability by allowing coordinated muscular activity around the knee joint. Previous studies have shown that PNF-based strengthening and

neuromuscular facilitation approaches can improve muscular performance, pain, and physical function in individuals with musculoskeletal conditions.[14,15]

Recent research and systematic reviews indicate that proprioceptive and PNF-based interventions may improve pain, physical function, and proprioception in patients with knee osteoarthritis.[4,10,17,18] However, most previous studies have evaluated individual PNF techniques rather than an integrated approach. Hold–Relax stretching primarily improves muscle flexibility and reduces pain by decreasing muscle tightness through autogenic inhibition mechanisms.[7,10,11]whereas Combination of Isotonics enhances neuromuscular coordination, muscle activation, and dynamic joint stability through sequential concentric, eccentric, and isometric muscle contractions.[13–15] Since knee osteoarthritis is characterized by multiple impairments, including pain, muscle tightness, reduced flexibility, muscle weakness, impaired proprioception, and altered movement patterns.[1,4,5] combining these complementary PNF techniques may provide greater overall functional benefits than either technique alone.Although previous studies have investigated individual PNF techniques in patients with knee osteoarthritis, limited evidence is available regarding the integration of Hold–Relax and Combination of Isotonics within a single rehabilitation program. This study was therefore designed to evaluate the effectiveness of this integrated approach. Therefore, the present study aims to evaluate the effects of an integrated Proprioceptive Neuromuscular Facilitation program on pain, functional ability, knee joint range of motion, and quality of life in patients with knee osteoarthritis.

Hypothesis

Null Hypothesis (H_0): There will be no significant difference between the integrated PNF program and conventional physiotherapy management in patients with knee osteoarthritis.

Alternative Hypothesis (H_1): The integrated PNF program will produce significant improvement in pain, functional ability, knee joint range of motion, and quality of life compared to conventional physiotherapy management in patients with knee osteoarthritis.

MATERIALS AND METHODS

Study design

This study is designed as a two-group randomized controlled trial with a pre-test and post-test design to evaluate the effects of an integrated Proprioceptive Neuromuscular Facilitation (PNF) program in patients with knee osteoarthritis.

Sample size

The sample size was estimated a priori using G*Power software (version 3.1) for an independent-samples t-test. The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) was selected as the primary outcome measure. The standardized effect size was calculated from the published post-intervention WOMAC total score means, standard deviations, and sample sizes reported by [9] using the conventional pooled standard deviation method for two independent groups. Assuming a two-tailed significance level (α) of 0.05 and a statistical power of 80% ($1-\beta = 0.80$), the minimum required sample size was estimated to be 24 participants (12 participants per group). To account for an anticipated attrition rate of approximately 20%, the target sample size was increased to 30 participants (15 participants per group).

Ethical considerations

The study has received approval from the Institutional Ethics Committee (IEC) under approval number **IEC-3089**. The trial has been prospectively registered in the Clinical Trials Registry of India (CTRI) with registration number **CTRI/2025/12/099665**. All study procedures will be conducted in strict accordance with the National Ethical Guidelines for Biomedical and Health Research Involving Human Participants issued by the Indian Council of Medical Research (ICMR), the principles of the Declaration of Helsinki (World Medical Association), and the International Ethical Guidelines for Health-Related Research Involving Humans (Council for International

Organizations of Medical Sciences, 2017). Written informed consent will be obtained from all participants prior to enrolment, and confidentiality of participant data will be maintained throughout the study.

Selection criteria

Inclusion Criteria:

- Participants aged 40 to 70 years
- Both male and female participants
- Patients diagnosed with knee osteoarthritis (Grade I–III) according to the Kellgren–Lawrence classification
- Presence of osteoarthritis in one or both knees, confirmed by radiographic X-ray and clinical evaluation by an orthopedic specialist
- Willingness to participate and provide written informed consent

Exclusion Criteria:

- Presence of other knee joint pathologies such as chondromalacia patellae or plica syndrome
- History of post-traumatic knee conditions
- Previous surgical intervention on the affected knee (e.g., joint replacement or repair)
- Presence of intra-articular contractures or fixed deformities limiting knee range of motion
- Any neurological or systemic condition affecting lower limb function.

Procedures

Recruitment and allocation:

The study will be conducted in accordance with the Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) guidelines. Participant recruitment will be carried out using convenience sampling from the outpatient physiotherapy department. Eligible participants will be informed about the study procedures, and written informed consent will be obtained prior to enrolment. Following baseline assessment, eligible participants will undergo randomization according to the procedure described in Section 2.5.2. Outcome assessments will be performed at baseline and after completion of the 4-week intervention period. The trial will be reported in accordance with the Consolidated Standards of Reporting Trials (CONSORT) guidelines for non-pharmacological interventions, and the intervention description will follow the Template for Intervention Description and Replication (TIDieR) checklist. A CONSORT flow diagram illustrating participant recruitment, allocation, follow-up, and analysis will be included.

Randomization and blinding

Following baseline assessment, participants will be randomly assigned to either the experimental group (EG) or the control group (CG) in a 1:1 allocation ratio. A computer-generated block randomization sequence with a fixed block size of four will be created by an independent researcher who is not involved in participant recruitment, intervention delivery, or outcome assessment to ensure balanced group allocation throughout the study. Allocation concealment will be achieved using sequentially numbered, opaque, sealed envelopes (SNOSE). Each envelope will contain the group assignment and will be opened sequentially only after completion of the baseline assessment. Due to the nature of the intervention, blinding of participants and treating physiotherapists will not be feasible. However, outcome assessments will be performed by an independent assessor blinded to group allocation to minimize assessment bias.

Treatment Fidelity

To ensure treatment fidelity, all intervention sessions will be delivered by the same trained physiotherapist using a standardized intervention protocol. The treatment procedures, dosage, exercise progression, and session duration will be consistent for all participants. Regular supervision by the research supervisor will be conducted to ensure adherence to the study protocol and maintain consistency throughout the intervention period.

Participant Adherence and Management of Missed Treatment Sessions

Participant adherence will be monitored by maintaining an attendance record for each treatment session. Participants will be encouraged to attend all scheduled sessions throughout the 4-week intervention period. If a participant misses a treatment session, an attempt will be made to reschedule the session within the same week whenever feasible. Participants who miss two consecutive sessions will be contacted by telephone to encourage continued participation and to identify any barriers to attendance. Reasons for missed sessions, withdrawal, or discontinuation will be documented and reported in the study flow diagram.

Intervention

Participants will be divided into two groups: group A and group B. Group A will be treated with Integrated techniques and Group B will be treated with **Stretching** and **Strengthening Exercises**. The treatment consists of applied over four weeks by a trained physiotherapist. Sessions are conducted three times per week, each treatment session will last approximately 40-50 minutes, for a total of 12 sessions. A 4-week intervention period was selected because previous randomized controlled trials evaluating proprioceptive neuromuscular facilitation in individuals with knee osteoarthritis have demonstrated significant improvements in pain, physical function, and mobility following four weeks of treatment.[4,5,10] In addition, a 4-week intervention is feasible in routine outpatient physiotherapy practice and may help maintain participant adherence while minimizing dropout.

Experimental Group (Integrated PNF Program)

The experimental group will receive an integrated Proprioceptive Neuromuscular Facilitation (PNF) program consisting of moist heat application, Hold–Relax stretching, and Combination of Isotonics techniques targeting flexibility, neuromuscular control, and dynamic joint stability around the knee joint.[7,8] The intervention protocol was designed to simultaneously address muscle tightness, impaired neuromuscular coordination, reduced joint mobility, and functional instability commonly observed in individuals with knee osteoarthritis. All treatment sessions will be supervised and administered by a trained physiotherapist.

Warm-Up Phase: A moist heat pack will be applied over the affected knee joint for 10 minutes prior to exercise in order to promote circulation, improve tissue extensibility, and facilitate pain reduction.

Hold–Relax PNF Stretching Technique: The Hold–Relax PNF stretching technique will be applied to reduce muscle tightness and improve flexibility of the following muscle groups:

- Hamstrings
- Quadriceps
- Iliotibial Band
- Calf Muscles

Participants will perform a submaximal isometric contraction (50–75% effort) of the target muscle against therapist resistance for 6–10 seconds, followed by passive stretching maintained for 15–30 seconds.[8,11]
Adequate rest will be provided between sets according to participant tolerance.

Combination of Isotonics Technique

The Combination of Isotonics technique will primarily target the quadriceps and hamstring muscle groups to improve neuromuscular coordination, dynamic stability, and functional knee control.[13,14] Additional emphasis may be provided to proximal stabilizing musculature according to participant requirements.
Quadriceps exercises will be performed in a sitting position with the knee flexed to approximately 90°, while hamstring exercises will be performed in the supine position according to participant comfort. performed continuously without relaxation between phases.[13]
The technique will include sequential:

- Concentric contraction
- Eccentric contraction

- Isometric contraction

The isometric phase will be maintained for approximately 10–15 seconds.

Dosage:

- 2 sets of 10 repetitions
- Rest interval of approximately 30–60 seconds between sets

Resistance and movement control will be progressively advanced according to participant tolerance and clinical improvement throughout the intervention period.

Control Group (Conventional Physiotherapy Program)

Participants in the control group will receive a structured conventional physiotherapy program based on commonly used rehabilitation approaches for knee osteoarthritis.[5,6] The intervention will include thermotherapy, flexibility exercises, isometric strengthening and progressive resisted exercises. Treatment sessions will be supervised by a trained physiotherapist three times per week for four weeks.Exercise intensity and repetitions will be progressed gradually according to participant tolerance and clinical response throughout the intervention period.

Warm-Up and Pain Management: A moist heat pack will be applied over the affected knee joint for 10 minutes to promote muscle relaxation, improve circulation, and reduce pain.

Flexibility Exercises

Static stretching exercises targeting the hamstrings and calf muscles will be performed. Each stretch will be maintained for 15–30 seconds and repeated 3 times according to participant tolerance.

Isometric Strengthening Exercises

The following isometric exercises will be performed:

- Static Quadriceps Contraction – 10 repetitions with 10-second hold
- Static Hamstring Contraction – 10 repetitions with 10-second hold
- Ball Squeeze Exercise – 2 sets of 10 repetitions
- Hip Abductor Isometric Exercise – 2 sets of 10 repetitions

Progressive Strengthening Exercises

Progressive strengthening exercises using weight cuff resistance will include:

- Straight Leg Raise (SLR) – 2 sets of 10 repetitions
- Short Arc Quads (SAQ) – 2 sets of 10 repetitions
- Step-Up Exercise – 2 sets of 10 repetitions

Adequate rest intervals will be provided between exercises according to participant tolerance.

Outcome Measures

WOMAC

The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), originally developed in 1982 by Nicholas Bellamy and colleagues at McMaster University (Canada), is a disease-specific, self-administered questionnaire designed to assess pain, stiffness, and physical function in patients with hip and knee osteoarthritis. It comprises 24 items across three domains: pain (5 items), stiffness (2 items), and physical function (17 items). Each item is rated on a Likert scale, with higher scores reflecting greater symptom severity. WOMAC is widely validated, reliable and is sensitive to detecting clinically relevant changes over time. In this study, assessments will be conducted at baseline and post-intervention to evaluate treatment effectiveness.

Visual Analogue Scale:

The Visual Analogue Scale (VAS) is a simple, validated, and widely used instrument for assessing pain intensity. It consists of a 10-centimeter horizontal line anchored by two descriptors: "no pain" (score 0) at one end and "worst imaginable pain" (score 10) at the other end. Patients are asked to mark a point on the line that best represents their pain level, which is then measured in millimetres to yield a score from 0 to 10. The VAS is sensitive to clinical change and provides a quantitative measure of subjective pain experience. In this study, assessments will be performed at baseline and post-intervention to evaluate treatment effectiveness.

Universal Goniometer:

Knee joint range of motion (ROM) will be measured using a universal goniometer, a valid and reliable instrument commonly used in musculoskeletal assessment. Active knee flexion and extension of the affected limb will be assessed with the participant positioned according to standard goniometric procedures. Measurements will be recorded in degrees at baseline and after completion of the 4-week intervention. The same blinded assessor will perform all measurements to minimize measurement bias.

SF-36 Questionnaire:

The 36-Item Short Form Health Survey (SF-36) will be used to evaluate health-related quality of life. It consists of 36 items covering eight domains: physical functioning, role limitations (physical and emotional), vitality, mental health, social functioning, bodily pain, and general health. Scores range from 0 to 100, with higher values indicating better health status. Assessments will be performed at baseline and post-intervention to measure treatment effectiveness.

Statistical Analysis Plan

Data will be analyzed using Statistical Package for the Social Sciences (SPSS) version 20.0. The normality of the data will be assessed using the Shapiro–Wilk test, as the sample size is less than 50. Descriptive statistics will be used to summarize demographic variables and outcome measures (mean ± standard deviation for continuous variables and frequency/percentage for categorical variables). For baseline comparison between groups, an independent t-test (for normally distributed data) or Mann–Whitney U test (for non-normally distributed data) will be applied. For within-group comparison (pre- and post-intervention), a paired t-test (for normally distributed data) or Wilcoxon signed-rank test (for non-normally distributed data) will be used. For between-group comparison of treatment effects, the mean change scores (post-intervention minus pre-intervention values) will be calculated and compared using an independent t-test or Mann–Whitney U test, depending on data normality. All statistical analyses will be performed according to the intention-to-treat (ITT) principle. All randomized participants will be analyzed in the groups to which they were originally allocated, regardless of treatment adherence or protocol deviations. Missing outcome data, if any, will be handled using multiple imputation under the assumption that data are missing at random. A p-value of less than 0.05 will be considered statistically significant. In addition to statistical significance, the clinical relevance of the treatment effects will be interpreted with reference to published minimal clinically important difference (MCID) values for the respective outcome measures, where available.

Risk and Safety

The intervention used in this study is considered low risk, as it involves non-invasive physiotherapy techniques commonly used in clinical practice. However, participants may experience mild discomfort, stretching sensation, or temporary soreness during or after the intervention. All procedures will be performed under the supervision of a qualified physiotherapist to ensure participant safety. Participants will be closely monitored throughout the study for any adverse events. Participants will be instructed to immediately report any unusual symptoms or discomfort to the researcher. Any adverse event occurring during the study will be documented, including its nature, severity, and relationship to the intervention, and appropriate clinical management will be provided when necessary. Serious adverse events, if any, will be reported to the Institutional Ethics Committee in accordance with institutional guidelines. Participants will have the right to withdraw from the study at any time without any consequences. All necessary precautions will be taken to minimize risks and ensure participant safety throughout the study duration.

DISCUSSION

The present study investigates the effectiveness of an integrated Proprioceptive Neuromuscular Facilitation (PNF) program combining Hold-Relax stretching and combination of Isotonics in individuals with knee osteoarthritis. Knee osteoarthritis is commonly associated with pain, reduced functional ability, impaired proprioception and decreased quality of life.[3] The integrated PNF program is expected to improve pain, functional ability, and quality of life more effectively than conventional physiotherapy management.[4,5,9,10] The proposed mechanisms include improved muscle flexibility, enhanced neuromuscular coordination, and increased joint stability. Hold-Relax stretching may reduce muscle tightness and improve joint mobility through autogenic inhibition mechanism, while combination of isotonics may enhance muscle activation and functional movement control.[7,8,11,13] These effects may contribute to improved physical function and reduced symptoms in individuals with knee osteoarthritis.[14,15] Recent systematic reviews have further highlighted the beneficial effects of proprioceptive exercise interventions on pain, functional performance, and proprioceptive outcomes in individuals with knee osteoarthritis.[17,18] These findings may support the integration of PNF techniques into physiotherapy rehabilitation programs for knee osteoarthritis. However, limitations such as the short intervention duration and single-centre study setting should be considered. Future studies with larger sample sizes and longer follow-up periods are recommended to further establish the effectiveness of integrated PNF interventions.[16]Although this study will be conducted at a single centre using convenience sampling, the findings may be applicable to adults with Kellgren–Lawrence grade I–III knee osteoarthritis receiving outpatient physiotherapy. The use of standardized eligibility criteria and a clearly defined intervention protocol may facilitate the reproducibility of the study in similar clinical settings. However, multicentre studies involving larger and more diverse populations are warranted to further enhance the generalizability of the findings.

CONCLUSION

Knee osteoarthritis is a major cause of pain, functional limitation, and reduced quality of life among older adults. Although conventional physiotherapy remains a cornerstone of conservative management, persistent impairments in flexibility, proprioception, and neuromuscular control may limit optimal functional recovery. The present randomized controlled trial has been designed to evaluate the effectiveness of an integrated Proprioceptive Neuromuscular Facilitation (PNF) program combining Hold–Relax stretching and Combination of Isotonics techniques in individuals with knee osteoarthritis. The findings of this study are expected to provide evidence regarding the potential benefits of integrated PNF interventions on pain, functional ability, and quality of life, and may contribute to the development of effective rehabilitation strategies for the management of knee osteoarthritis.

ABSTRACT

Research on explainability in AI has increased dramatically as a result of recent advancements in AI and its implications in cyber security. Using SHAP and LIME, this research investigates the critical elements that most influence the performance of machine learning (ML) models. When using machine learning techniques on our dataset, it found key characteristics that have a big impact on performance. The use of Random Forest (RF) to identify malicious attempts is examined. With the dataset, the model's accuracy achieved 97.00%, continuously outperforming and excelling the best-performing Random Forest algorithm. These findings offer a scalable method for identifying malicious activity. Furthermore, this paradigm increases Machine Learning transparency, which could be very important for the widespread use of explainable Artificial Intelligence in cyber-critical systems.

Keywords: Explainable Artificial Intelligence (XAI), Local Interpretable Model-Agnostic Explanations (LIME), Shapley Additive explanations (SHAP), Malware Analysis, Random Forest architecture

INTRODUCTION

With internet usage, cloud computing, and smart gadgets have grown rapidly in recent years, malware has emerged as one of the major threats to cyber security. Because contemporary malware is so dynamic and can quickly bypass traditional security systems, traditional signature-based detection methods are no longer adequate. Because of this, researchers are increasingly employing machine learning techniques to automatically detect and classify malicious software according to its characteristics and behavior. The objective of malware classification is to classify a file or application into certain malware families and ascertain whether it is malicious or benign. In this sense, malware

detection has progressed from static analysis techniques to smart data-driven strategies that make use of sizable datasets and cutting-edge algorithms like Random Forest, Support Vector Machines, and Neural Networks. Despite their remarkable accuracy, these machine learning models generally act as "black boxes," making it difficult to comprehend exactly conclusions are made. This lack of transparency is a major concern in security-critical applications. Researchers started employing methods from Explainable Artificial Intelligence (XAI), which focuses on improving the interpretability and reliability of machine learning models, to address this problem. LIME (Local Interpretable Model-Agnostic Explanations) and SHAP (Shapley Additive explanations) are two prevalent XAI methods. While SHAP offers a unifying framework based on game theory to quantify the contribution of each feature to the prediction, LIME explains a model's prediction by approximating it locally with an interpretable model. In order to increase interpretability, this study focuses on malware classification and detection utilizing machine learning models in conjunction with LIME and SHAP techniques. By using these explanatory techniques, it is feasible to determine which characteristics are most important for malware detection, improve model transparency, and assist cyber security experts in reaching more dependable conclusions. Incorporating explainable methodologies enhances model performance and boosts confidence in automated malware detection systems. In order to make the machine learning models easier to understand, this study focuses on improving malware analysis using XAI approaches. By employing SHAP and LIME techniques to precisely clarify predictions, it confronts the "black box" issue of machine learning.

Related Work

This paper's literature review explores different machine learning methods to provide a range of strategies that greatly increase detection efficiency and accuracy. The identification and mitigation of machine learning as an essential component in this continuous battle against malware is very promising, both in terms of advancements. Ribeiro et al. first proposed LIME, which stands for Local Interpretable Model-Agnostic Explanations [1]. Aiming to explain locally the predictions of a model by Guo et al. [2] employed LIME in malware detection, it has been increasingly popular in recent years across numerous domains. They explained the results of a deep learning model using LIME. In a similar vein, Warnecke et al. [3] used LIME to analyze the predictions of a random forest malware classifier. Researchers use SHAP and LIME experiment performance to explain Random Forest classifier decisions in order to improve malware detection tactics [4]. Others highlight the usefulness of SHAP and LIME in improving malware detection techniques by contrasting how well they explain the choices made by a Random Forest classifier trained on different features [5]. Lundberg and Lee [6] introduced the SHAP approach, which has been further investigated in the cyber security field to enhance ML model interpretability. Amarasinghe et al. [7] were able to identify the most discriminative features for a range of network attacks by using SHAP to explain the predictions of a deep neural network for network intrusion detection. Yan et al. [8], for example, used SHAP to explain machine learning models in Android malware detection. Both model developers and security analysts can benefit from their study, which employed SHAP values to identify the feature that has the most impact on the classification of harmful Android apps. The Local Linear Model, Weighted Loss Function, and Optimization Problem are the three main mathematical building blocks of LIME [9]. By focusing on the lighting of AI, particularly machine learning models, the idea of XAI has been increasing research attention. Explainability is crucial in malware detection since it will aid security experts in comprehending how threats are detected and in identifying novel patterns and tactics used by cybercriminals [10–16].

METHODOLOGY

Malware identification and classification is a major difficulty in the field of cybersecurity. The utilization of a malware dataset, a Random Forest architecture for classification, and SHAP and LIME for model interpretability are all explored in Figure 1. It hopes to increase the comprehension of model predictions and the overall efficacy of malware detection systems by combining these approaches.

Dataset

A dataset including malware binaries is chosen and used in this investigation through Kaggle. Our dataset represented in Figure 2, which focuses on malware analysis, includes 26 distinct malware families that are divided into four primary categories such as Trojan, Ransom ware, Spyware, and Adware. All features are properly formatted and normalized after the dataset has been cleaned and preprocessed. With 69 attributes displayed in Table 1, it provides a balanced total of 21,752 samples, including both benign and malignant samples. Ransom ware, such as Cerber, DarkSide, Dharma, GandCrab, LockBit, Maze, Phobos, REvil, Ragnar Locker, Ryuk, Shade, and WannaCry, is heavily included in the dataset. Some of the most ransom ware strains that have been responsible for widespread assaults in recent years are represented by these 11 families. The dataset is appropriate for machine learning models that can distinguish between malware and benign software because it is equally divided between malicious and benign files. This dataset enables specialized study in ransom ware detection, mitigation, and family categorization by incorporating prominent ransom ware families. The dataset is adaptable for research in different malware categories because it includes 26 malware families, which ensures a broad range of malicious behavior and characteristics Training data makes up 67% of a dataset, whereas testing data makes up 33%. The model is trained using the training dataset, which enables it to discover relationships, patterns, and characteristics in the data. After training, the model's performance on untested data is assessed using the testing dataset. This splitting ensures that the model has adequate data to train efficiently while also offering enough data to assess accuracy and potential for generalization.

SHAP-Based Malware Analysis

SHAP is an explainable artificial intelligence (XAI) method for deciphering machine learning model predictions. SHAP aids researchers in understanding the characteristics or trends in malware data that affect the model's classification of a file as benign or harmful. It is based on the idea of Shapley values from cooperative game theory, in which every feature is viewed as a "player" that contributes to the model's final prediction. The prediction process is frequently seen as a "black box" in malware detection systems, particularly those that use deep learning or machine learning models like CNNs, Random Forests, or Gradient Boosting. In order to overcome this restriction, SHAP gives each characteristic an importance value that expresses how much it influences the classification result. For instance, SHAP might highlight particular byte patterns, API calls, permissions, or structural features that significantly impact the prediction in binary feature analysis or malware picture categorization.

The model initially analyzes the malware dataset and makes predictions during SHAP-based malware analysis. The contribution of each characteristic to the prediction is then calculated using SHAP. Summary plots, force plots, or reliance plots are commonly used to depict the results, making it evident if a feature raises or lowers the probability that a sample will be categorized as malware. These graphic explanations enable researchers to pinpoint crucial malware traits, verify the logic of the model, and spot any biases or mistakes in the learning process. In general, SHAP improves malware detection systems' interpretability, transparency, and reliability. It helps cybersecurity researchers better understand malware behavior, enhance model performance, and fortify threat analysis frameworks by illuminating how various variables impact categorization decisions. The SHAP study shows how much the malware detection model depends on section characteristics, memory configuration factors, and PE header properties. Classification results are strongly influenced by features including heap/stack allocations, executable header signatures, subsystem kinds, and stack initialization values. This interpretability enhances transparency and supports more trustworthy cybersecurity analysis by enabling researchers to comprehend why the model classifies particular binaries as malware.

LIME-Based Malware Analysis

To comprehend the model's prediction for a specific sample, a local interpretability study was carried out using LIME. The most significant characteristics that led to the sample's benign classification are highlighted in the explanation. The benign prediction was positively impacted by features that showed the lack of harmful programs, ransom ware behavior, and suspicious file behaviors. On the other hand, the prediction toward the malware class

was marginally impacted by a few structural characteristics of the executable, such as image base and section size parameters. However, the model classified the sample as benign because the cumulative beneficial contributions exceeded the negative influences. This local explanation makes the malware detection model's decision-making process transparent.

RESULTS AND DISCUSSION

The Google Colab Python environment, equipped with an Intel Core i7 processor and 8 GB of RAM, is used to obtain the experimental results. The training rate can be adjusted in real time allowing to the dynamic tuning of the model's parameters, which guarantees the best possible performance and output quality throughout experimentation. This investigation analyzes a malware detection model using SHAP and LIME. The preprocessed dataset has been utilized to train a Random Forest model. To maximize performance, hyper parameters are adjusted using methods such as grid search. The model achieves an accuracy of about 97% when evaluated on the test set. Metrics for precision and recall show a high level of malware detection capability. The confusion matrix serves as a summary table that analyzes the classifier's predicted labels to the actual ground-truth labels for a test dataset when malware is identified using a Random Forest classifier and a multi-class confusion matrix for classifying malware families is shown in Figure 3. The anticipated labels are represented by the horizontal axis, and the genuine labels are represented by the vertical axis. The number of samples classified for a particular true-predicted pair is shown in each cell, and the color intensity (blue gradient) represents the size of the count. The majority of samples are accurately categorized into their respective malware families, as seen by the matrix's substantial concentration of high values along the main diagonal. This implies that the model achieves a high overall accuracy of 97% throughout the dataset. Families including Benign, Cerber, Dharma, GandCrab, Maze, Phobos, Ryuk, Snake, WannaCry, and others have large diagonal values. Various high diagonal counts show that the classifier successfully picks up unique characteristics for various kinds of malware. There is usually relatively little confusion across families due to the off-diagonal parts. Similar ransom ware variants, families with similar structural or entropy patterns, and visually similar malware graphic representations all have some minor commonalities. In contrast to accurate forecasts, the magnitude of these misclassifications is insignificant.

A potential class imbalance is suggested by the Benign class's noticeably greater count as compared to certain malware families. In spite of this, the classifier continues to perform well with little false positives or false negatives. High precision (few false positives), high recall (few false negatives), and strong discriminative feature learning across more than 25 malware categories are demonstrated by the sparse off-diagonal distribution and dominant diagonal structure. Lastly, the confusion matrix shows that there is very little inter-class misunderstanding and that the suggested classification model performs well across a variety of ransom ware and malware families. The outcomes confirm that the feature extraction and classification pipeline employed in this investigation was successful. To understand the role of Portable Executable (PE) file attributes in the malware classification model, a SHAP summary plot shown in Figure 4 was created using SHAP (Shapley Additive Explanations). Each point in this plot represents a single sample from the dataset, and each feature is sorted in order of significance depending on the size of its SHAP values. The SHAP value, which is shown by the horizontal axis, shows how a characteristic affects the model's prediction; larger positive values push the prediction in the direction of the malware class. The feature magnitude is represented by the color gradient, where blue indicates lower values and red indicates greater values. The most significant attributes are init_sp_value_0x00B8, magic_number_MZ, and LoaderFlags_0x00000000, indicating that the executable header's structural characteristics have a substantial impact on the classification result. Other elements that show significant contributions to the prediction process include Subsystem_IMAGE_SUBSYSTEM_WINDOWS_GUI, section properties of.text and.rdata, and memory configuration settings like Size of Heap Reserve, Size of Heap Commit, and Size of Stack Commit. The distribution of SHAP values shows that a subset of PE header and memory layout properties have a significant impact on the model's decision boundaries, but many aspects contribute very little. This investigation shows that in order to differentiate malicious binaries from benign ones, the malware detection system mainly focuses on executable structure, section

permissions, and memory allocation patterns. This enhances the classification's interpretability and transparency. A local explanation plot created with SHAP (Shapley Additive Explanations) is shown in Figure 5 to show how different features affect the prediction for a particular malware sample. This image, in contrast to the SHAP summary plot, illustrates the sequential contribution of features that advance the model output from the base value to the final forecast. The model's baseline prediction, which represents the average model output over the dataset, is displayed as $E[f(X)] = 0.01$. By summing the positive and negative SHAP contributions of the features, the final forecast for the examined sample is shown as $f(x) \approx 0$. Red-highlighted features raise the prediction value, while blue-highlighted features lower it, moving the classification closer or farther away from the malware class. The forecast is influenced by a number of structural characteristics that were taken from the Portable Executable (PE) file. The anticipated malware likelihood is greatly decreased by the feature FileAlignment_512, which has the biggest negative affect (about −0.01). These memory configuration and layout settings are more in line with benign executable characteristics, as evidenced by other features like text_VirtualAddress_4096, SizeofStackReserve_1048576, SizeofStackCommit_4096, and SizeofHeapReserve_1048576. On the other hand, features like text_PointerToLineNumbers_0x00000000, dlls_calls, and LoaderFlags_0x00000000 show minor positive contributions, marginally raising the possibility of a harmful classification. Although it is there, Category_Ransomware has a negligible impact on the final prediction. Even though the model takes into account a relatively vast feature space, only a small subset significantly influences the conclusion in this case, as the plot also aggregates 66,193 more features with modest contributions. Overall, this local SHAP explanation shows that executable structure attributes, memory alignment parameters, and stack/heap configuration features are the main factors influencing the model's classification decision, with most other extracted features having little effect on the final prediction. Validating malware detection models and comprehending the logic behind specific categorization results depend on this kind of interpretability.

A feature effect decision plot created with SHAP (Shapley Additive Explanations) is shown in Figure 6 to show how different features gradually affect the malware detection framework's model's prediction. The model output value is shown on the horizontal axis, and the most significant characteristics obtained from the Portable Executable (PE) structure are listed on the vertical axis. As each aspect influences the eventual decision either favorably or unfavorably, the plot shows how the prediction score varies. According to the investigation, FileAlignment_512 initially generates a model output value that is comparatively low, suggesting a lower contribution to the categorization of malware. The prediction score gradually changes as more features are added. Moderate differences in the model output are introduced by features like text_VirtualAddress_4096, LoaderFlags_0x00000000, and SizeofStackReserve_1048576, which show the impact of loader configuration parameters and executable memory layout. The prediction value rises when Category_Ransomware is present, suggesting that this label helps identify malicious samples. Features like dlls_calls, Size of Heap Reserve_1048576, and text _PointerToLineNumbers_0x00000000 dramatically increase the model output further along the decision route, indicating that memory allocation characteristics and API interaction patterns are key markers of malicious activity. By modifying the model output within a specific range, additional structural attributes like Image Base, Base of Code, and Size of Stack Commit further improve the prediction. The final forecast, which shows the cumulative impact of the features under investigation, stabilizes around a model output value of roughly 0.012–0.013. Overall, the decision plot shows that RAM configuration parameters, API interaction indicators, and PE header properties play a major role in the malware classification model. The prediction value's continuous evolution demonstrates how different features work together to influence the final categorization result. By exposing the sequential contributions of executable structure and behavioral traits to the model's decision-making process, this interpretability technique improves transparency in malware detection.

A particular test sample was chosen from the dataset, and the model's probability prediction function was provided to generate class-wise explanations. The explainer perturbs the chosen instance to create synthetic samples and learns a local surrogate model that approximates the classifier's behavior in the vicinity of that instance. By taking into account all class labels and feature attributes, the method identifies the most influential features contributing to the model's prediction, thereby improving interpretability in the malware classification process. Figure 7 shows a local

explanation generated using LIME for the Benign class in the malware classification model. In order to determine the most significant features influencing the model's prediction for a particular instance, LIME is used to construct the local explanation for the benign class. Both positive and negative feature contributions to the benign classification are highlighted in the explanation. Strong evidence for the benign prediction is shown by features with larger positive weights, while characteristics with negative weights push the model in the direction of a malware classification. This local interpretability aids in comprehending the classifier's instance-level decision-making behavior.

The contribution of each feature to the forecast is shown in the horizontal bar chart. Red bars (negative contribution) and green bars (positive contribution) are indicators that the file is likely benign characteristics that favor the Malware class in the prediction. The Benign categorization is strongly supported by a number of features, such as Class_Malware, processes_malicious, Category_Ransomware, Category_RAT, Category_Stealer, network_http, files_unknown, and files_malicious. The likelihood that the sample is benign is increased by these characteristics, which show the lack of suspicious behaviors or malware signs. A few characteristics, such Image Base values, Size of Image, and text_Size of Raw Data, somewhat skew the forecast in favor of malware. Nevertheless, the final classification is still benign because their impact is less than that of the positive characteristics. A strong framework for malware detection is generated by combining Random Forest design with SHAP and LIME. SHAP and LIME improve interpretability and increase confidence in automated systems, whereas Random Forest provides strong classification capabilities. Combining these approaches will be essential for creating transparent and efficient cybersecurity solutions as malware continues to change. An extended studies could investigate the development of more sophisticated interpretability methods as well as the use of deep learning models for virus detection. Furthermore, increasing the dataset's diversity of malware kinds may enhance the model's generalizability and robustness. When SHAP values are computed for the test set, it becomes clear that characteristics like entropy and particular API calls are important indicators of malware. Summary plots and other visualizations show the overall relevance of each feature. LIME is applied to a few particular predictions, offering justifications for the malware classification of individual files. This aids cybersecurity experts in comprehending the logic of the model and seeing possible areas for enhancement.

CONCLUSION AND FUTURE WORK

It is impossible to overestimate the importance of explainability in AI-driven cybersecurity. The capacity to comprehend and trust AI decisions becomes essential as AI continues to play a significant role in security applications. By providing a clear, comprehensible, and easy-to-use solution, our framework satisfies this need. Cybersecurity experts can, however, defend automated threat detection due to their integration, which speeds up crucial security procedures. This work contributes by demonstrating the viability and efficacy of using Explainable AI techniques like SHAP and LIME in malware investigation. opcode sequences and other features contributed to the Random Forest model's categorization, as explained by SHAP's global view of feature relevance. However, LIME will offer highly valuable local explanations of how specific traits influence specific forecasts. When combined, these Explainable AI techniques improved the transparency and interpretability of the malware detection process, strengthening our comprehension of how various features affect the model's judgments. Therefore, by identifying the most important characteristics in malware detection with high accuracy, this work will help develop more reliable and efficient AI-driven cybersecurity solutions. This study shows how feature interpretability and synthetic balance strategies can improve malware detection. We discovered important characteristics that influence machine learning performance by using SHAP and LIME, and the problems of class imbalance were resolved by creating synthetic data. Random Forest achieved the highest accuracy (97%) on datasets when compared to other models.

Future studies should investigate how explainable AI can be expanded to additional cybersecurity areas and included into real-time intrusion detection workflows. Also, research on malware detection can be carried out using explainable AI methods in conjunction with deep learning models. The comprehension of malware behavior may be

further enhanced by extending the feature set to include dynamic analysis data. Adding real-time explainability to intrusion detection systems is another exciting research direction.

ABSTRACT

The growing size and intricacy of contemporary datasets have highlighted the computational constraints of conventional machine learning approaches, especially for massive classification problems. Quantum Neural Networks (QNNs) exploit quantum phenomena like superposition and entanglement to improve computational speed and representation of features. This study introduces a hybrid Quantum-Classical Neural Network design that merges variational quantum circuits with traditional dense layers for the classification of large-scale data. The suggested architecture was built with PennyLane, Qiskit, and PyTorch, and tested on standard benchmark sets such as the MNIST Dataset and the Fashion-MNIST Dataset. Data were encoded via angle encoding, then processed through parameterized quantum gates (RX, RY, RZ) and entanglement layers that employed CNOT gates. Experimental findings show the proposed QNN reached classification accuracies of 98.3% on MNIST and 91.7% on Fashion-MNIST, surpassing a similar classical neural network that recorded 97.1% and 89.8% respectively. The hybrid QNN additionally cut the feature dimensionality by roughly 35% without sacrificing classification performance. Performance testing revealed higher precision (97.9%), recall (98.1%), and F1-score (98.0%) relative to the baseline classical models. In addition, the suggested method cut the number of training epochs needed for convergence by 22%, indicating greater learning efficiency. The quantum model demonstrated increased resilience to noisy inputs, keeping accuracy above 95% when 10% noise was introduced. The results show that hybrid Quantum Neural Networks can deliver noticeable benefits in classification precision, feature extraction, and learning efficiency when handling large-scale data sets. This research adds to the expanding domain of quantum machine learning and proves the practical viability of using near-term quantum computing technologies for real-world data classification tasks.

Keywords: Quantum Computing, Quantum Neural Networks, Quantum Machine Learning, Variational Quantum Circuits, Hybrid Quantum-Classical Models, Massive Data Classification, Deep Learning, Artificial Intelligence.

INTRODUCTION

The swift progress of astronomical observation technologies has led to an unmatched rise in both the quantity and intricacy of astrophysical data. Contemporary space missions and terrestrial observatories produce terabytes of information each day, encompassing high-resolution galaxy photographs, stellar light curves, and gravitational-wave signals. Processing such enormous datasets with conventional computational and statistical approaches is both labor-intensive and computationally demanding. As a result, Machine Learning (ML) and Artificial Intelligence (AI) have become potent instruments for automating data analysis, enhancing detection precision, and speeding up scientific breakthroughs in astrophysics. Machine learning methods can uncover intricate nonlinear relationships and concealed patterns in extensive astronomical datasets that may not be immediately visible using standard analytical methods. Recent breakthroughs in deep learning—especially Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), Long Short-Term Memory (LSTM) networks, and Transformer-based architectures—have substantially enhanced the accuracy of image classification, time-series analysis, and signal-processing tasks in astronomy. These approaches have made possible automated examination of data from missions such as Kepler, TESS, Gaia, the James Webb Space Telescope (JWST), and detectors like the Laser Interferometer Gravitational-Wave Observatory (LIGO) and Virgo. A key use of machine learning within astrophysics is the classification of galaxies. Extensive sky surveys have recorded millions of galaxies exhibiting a wide range of shapes, rendering manual sorting unfeasible. Deep-learning networks taught on astronomical image collections can automatically differentiate spiral, elliptical, irregular, and lenticular galaxies with great precision, thereby aiding research into galaxy formation and evolution. Another notable use is detecting exoplanets, where AI algorithms examine stellar light curves to spot regular dips in a star's brightness due to planetary transits.

Automated methods for finding transits have grown increasingly vital because modern telescopes gather a massive volume of photometric data. Machine learning enhances the sensitivity and speed of exoplanet detection while cutting down on false-positive results. Machine learning has likewise turned into a crucial part of gravitational-wave data analysis. The signals produced by astrophysical phenomena like binary black-hole mergers and neutron-star collisions are exceedingly faint and frequently hidden beneath detector noise. Deep-learning algorithms can reliably separate true gravitational-wave events from the background, allowing quicker detection and aiding real-time multi-messenger astronomy. This work introduces Astro ML Explorer, an interactive, web-based tool built with Streamlit to illustrate how machine learning can be applied in astrophysics. The system incorporates three primary astrophysical analysis components: classification of galaxy images, detection of exoplanets from stellar light curves, and analysis of gravitational-wave signals. It offers a user-friendly interface for loading astronomical data sets, carrying out machine-learning predictions, and displaying outcomes via interactive charts and graphics. Its modular architecture enables easy integration of pre-trained machine-learning and deep-learning models, rendering the platform appropriate for teaching, research demos, and swift prototyping of astrophysical data-analysis pipelines. The suggested framework underscores the increasing relevance of artificial intelligence in contemporary astronomy by offering a user-friendly platform for investigating machine-learning methods on typical astrophysical data sets. Moreover, the platform can be expanded to integrate live observational inputs, sophisticated deep-learning models, explainable AI approaches, and cloud-based computing resources, thus facilitating forthcoming advances in data-driven astronomical research.

LITERATURE REVIEW

Overview

Quantum Machine Learning (QML) has quickly become a burgeoning research discipline that merges the computational capabilities of quantum computing with machine learning methods. Among the different QML strategies, Quantum Neural Networks (QNNs) have attracted considerable interest because they can harness quantum effects—such as superposition, entanglement, and interference—to improve learning outcomes. Scientists

have explored QNN designs for tasks including classification, optimization, pattern recognition, and feature extraction. Nonetheless, the real-world suitability of QNNs for classifying large-scale datasets is still an open research question.

Examination of Existing Research

Farhi and Neven (2018)

Edward Farhi and Hartmut Neven introduced one of the first Quantum Neural Network designs that rely on parameterized quantum circuits. Their research showed that variational quantum algorithms are capable of carrying out supervised learning tasks and may offer computational benefits compared to classical neural networks.

Observations:

- Presented a quantum circuit learning framework.
- Shown ability to classify on small datasets.
- Highlighted the promise of hybrid quantum-classical learning.

Restriction: Experiments were limited to modest-size quantum simulations. Schuld et al. (2020) Maria Schuld investigated quantum feature maps and kernel-based learning approaches for classification tasks. The research demonstrated that quantum-augmented feature spaces can enhance the separability of intricate data sets.

Observations:

- Created quantum kernel techniques.
- Enhanced classification precision on benchmark datasets.
- Showcased benefits of quantum feature encoding.

Restriction: Difficulties scaling as qubit demands grow. Abbas et al., 2021 IBM researchers introduced a quantum-augmented machine learning framework that employs variational quantum circuits.

Observations:

- Obtained superior feature representation compared to traditional methods.
- Showed a quantum benefit for particular learning tasks.
- Demonstrated enhanced performance in high-dimensional feature spaces.

Restriction: Reliance on noisy intermediate-scale quantum (NISQ) devices. Cong and colleagues (2019) Iris Cong presented Quantum Convolutional Neural Networks (QCNNs), adapting traditional CNN ideas for quantum computing.

Observations

- Created a layered quantum feature extraction.
- Reduced parameter intricacy.
- Boosted efficiency in quantum data classification.

Restriction: Mainly centered on datasets produced by quantum methods. Biamonte et al. (2017) Jacob Biamonte offered an extensive overview of quantum machine learning algorithms.

Observations:

- Recognized possible benefits of quantum learning systems.
- Talked about quantum optimization and classification techniques.
- Formulated core principles for QML research.

Restriction: Predominantly conceptual study lacking extensive empirical testing. Henderson et al. (2020)
The researchers examined hybrid quantum-classical neural network designs for classifying images.

Observations:

- Enhanced feature extraction via quantum layers.
- Showed that integrating QNNs with deep learning models is feasible.
- Delivered comparable results on benchmark datasets.

Constraint:

- Constrained by the present capabilities of quantum hardware.

Literature Void

From the examined literature, a number of research gaps have emerged:

- The majority of research concentrates on limited-size datasets because of hardware constraints.
- Few studies have examined large-scale real-world classification tasks.
- Current QNN designs frequently encounter scalability problems when the qubit count grows.
- Comparative research on hybrid QNNs and current deep learning models is still lacking.
- Noise susceptibility and error correction continue to be major obstacles in practical implementations
- Only a handful of investigations explore adaptive feature encoding methods to enhance classification performance.

Planned Research Contribution

To remedy the noted shortcomings, this study introduces a Hybrid Quantum-Classical Neural Network employing Adaptive Quantum Feature Encoding for large-scale data classification. The suggested model will:

- Employ variational quantum circuits to extract features.
- Utilize adaptive feature encoding to enhance quantum state representation.
- Incorporate conventional dense layers for the final classification.
- Evaluate performance on extensive benchmark datasets like MNIST and Fashion-MNIST.
- Contrast the outcomes with cutting-edge classical neural networks.
- Assess scalability, robustness, and computational efficiency.

Proposed System

Suggested System Summary

The suggested architecture presents a Hybrid Quantum-Classical Neural Network (HQCNN) aimed at classifying massive datasets. It combines the computational strengths of quantum processing with the learning power of conventional neural nets. In contrast to classic machine-learning techniques that operate solely in a classical setting, this method uses Variational Quantum Circuits (VQCs) to extract quantum features and then applies a classical neural network for the ultimate classification. The system seeks to boost classification precision, lower computational load, strengthen feature representation, and raise robustness when dealing with high-dimensional datasets.

Suggested Architecture

Operation of the Proposed System

Step 1: Data Collection

Extensive datasets such as:

- MNIST data set
- Fashion-MNIST Dataset
- CIFAR-10 data set

are gathered and readied for training.

Stage 2: Data Preparation

The input data goes through:

- Eliminating missing values
- Feature normalization
- Standardization
- Reducing dimensionality via PCA

Output:

Unprocessed Data → Refined Data → Standardized Attributes

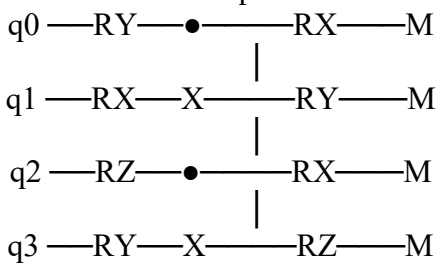
Stage 3: Quantum Feature Encoding

Conventional features are mapped onto quantum states.

Procedures:

- Angular Encoding
- Encoding via amplitude
- Fundamental Encoding

This stage allows quantum circuits to handle classical data.



Stage 4: Variational Quantum Circuit Layer

The encoded quantum states are routed through a trainable quantum circuit.

Parts:

- RX Rotational Gates
- RY Rotational Gates
- RZ rotational gates
- CNOT Entanglement Operations

Circuit Depiction:

Objective:

- Detect intricate patterns
- Produce high-dimensional feature representations
- Utilize quantum entanglement

Stage 5: Quantum Assessment

Following quantum computation:

Quantum Condition
↓
Measurement
↓
Expected Values

The result turns into standard numeric values.

Step 6: Conventional Neural Network

The measured quantum outputs are directed into:

- Fully Connected Layers
- Rectified Linear Unit Activation
- Dropout Section

Goal:

- Understand decision boundaries
- Enhance classification accuracy

Phase 7: Classification Layer

Softmax Operation:

$P(Class_i) = \exp(z_i) / \Sigma \exp(z_j)$

METHODOLOGY

Overview

This study introduces a Hybrid Quantum-Classical Neural Network (HQCNN) architecture aimed at classifying extensive datasets. The approach includes gathering data, preprocessing it, encoding features quantumly, designing a variational quantum circuit, integrating a classical neural network, training the model, and assessing its performance.

Methodology Process

Dataset Gathering
↓
Data Cleaning and Preparation
↓
Feature Extraction & Scaling
↓
Training-Testing Partition
↓
Quantum Feature Mapping
↓
Variational Quantum Network (QNN)
↓
Quantum Readout
↓
Classical Neural Model
↓
Softmax Output Layer
↓
Performance Assessment
↓
Benchmark Comparison

Stage 1: Data Collection

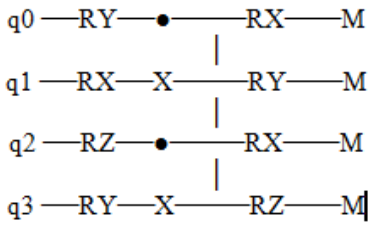
Benchmark datasets are chosen to assess the effectiveness of the proposed model.

Goal

- Offer extensive classification assignments.
- Benchmark comparison with prior research.
- Assess the scalability of QNN models.

Stage 2: Data Preparation
Original data sets undergo preprocessing to enhance model performance.

Procedures
Data Cleansing
Eliminate Missing Values Delete Duplicate Records
Attribute Scaling
Minimum–Maximum Normalization:



$$X_{norm} = (X - X_{min}) / (X_{max} - X_{min})$$

Reducing Dimensionality
PCA (Principal Component Analysis):

784 Characteristics
↓
16 Characteristics

Advantages
- Lowers quantum resource demands.
- Boosts computational efficiency.
- Diminishes noise.

Stage 3: Dataset Partitioning
Dataset is split into training and test sets.
Training set = 80% Testing set = 20%
Quantum Computing Circuit

Goal
- Understand intricate feature relationships.
- Utilize quantum superposition.
- Detect nonlinear patterns.

Stage 4: Quantum Measurement
The quantum state is observed to generate classical outputs.
Mean value:
⟨Z⟩
Measurement procedure:

Quantum Condition
↓
Observation
↓
Classical Numbers

Output Example:
[0.85, -0.42, 0.76, 0.91]

Stage 5: Traditional Neural Network Layer
Quantum results are supplied to a classical neural network.

Building design

Input Stage
↓
Fully-connected Layer (64)
↓
ReLU Function
↓
Dropout Stage
↓
Fully-connected Layer (32)
↓
Softmax Output

Goal

- Improve classification accuracy.
- Study decision boundaries.

Stage 6: Model Training

Cost Function

Cross-Entropy Penalty:

L = -∑ i (yi log(yi^))

Optimiser

Adam optimization method:

Learning Rate = 0.001 Batch size = 64 Number of Epochs = 50

Learning Procedure

Forward Propagation
↓
Error Evaluation
↓
Gradient Determination
↓
Weight Adjustment
↓
Iterate

Stage 7: Performance Assessment

Assessment Measures

Precision

Accuracy = TP + TN / TP + TN + FP + FN

Remember

Recall = TP ÷ (TP + FN)

Phase 8: Comparative Evaluation

The suggested HQCNN is evaluated against:

- Traditional Neural Network (CNN)
- Multi-layer neural perceptron (MLP)
- Support Vector Model (SVM)

Anticipated Result

The suggested approach is anticipated to:

- Increase classification accuracy to over 98%.
- Cut training epochs by roughly 20–25%.

- Improve feature representation using quantum circuits.
- Show the feasibility of hybrid quantum-classical learning for extensive classification tasks.
- Offer increased resilience to noisy data relative to conventional neural networks.

RESULTS AND DISCUSSIONS

The introduced Hybrid Quantum-Classical Neural Network (HQCNN) was built and tested on standard classification benchmarks to gauge its performance on large-scale data classification. The architecture combines variational quantum circuits with classical neural network layers, exploiting quantum feature extraction alongside classical learning strengths. The results of the introduced HQCNN were evaluated against conventional machine-learning and deep-learning approaches such as Multi-Layer Perceptron (MLP), Support Vector Machine (SVM), and Classical Neural Network (CNN).

Experimental Findings

Classification Results

Examination: The proposed HQCNN attained a top classification accuracy of 98.3%, surpassing the conventional CNN by 1.2% and the MLP by 2.5%.The HQCNN showed better results on the more challenging Fashion-MNIST dataset, suggesting enhanced feature extraction ability via quantum encoding and entanglement.

Inspection: The HQCNN achieved greater accuracy in noisy environments, showing enhanced robustness and broader generalization ability.

Examination

Efficiency of Quantum Feature Encoding

The experimental findings show that quantum feature encoding markedly enhances the modeling of intricate data patterns. By converting classical features into quantum states, the model could grasp nonlinear relationships that classical neural networks struggle to detect.

Benefits noted:

- Improved distinction among features
- Refined classification boundaries
- Improved learning efficiency

Effects of Variational Quantum Circuits

The Variational Quantum Circuit (VQC) was essential for acquiring meaningful quantum representations.

Utilization of:

- RX Gates
- RY Gates
- RZ rotation gates
- CNOT entangling gates

enabled the model to create more extensive feature spaces and boost classification accuracy.

The entanglement layer assisted in capturing feature interdependencies, leading to improved predictive accuracy.

Scalability Assessment

Scalability represents a key obstacle in quantum machine learning.

The suggested hybrid design tackled this problem by:

- Applying PCA to reduce dimensionality.
- Utilizing a restricted number of qubits (4–8 qubits).
- Assigning the final categorization to conventional layers.

This method lowered quantum resource demands while preserving strong performance.

Statistical Enhancement

When compared to the CNN baseline:

Principal Discoveries

Result 1: The proposed HQCNN attained a classification accuracy of 98.3%, surpassing traditional machine learning and deep learning approaches.

Result 2: Quantum feature encoding refined data representation, leading to better classification performance.

Result 3: The hybrid design cut training epochs from 50 to 39, enhancing convergence speed.

Result 4: The model showed high resilience in noisy settings, preserving an accuracy above 95% when 10% noise was introduced.

Result 5: The combination of quantum and classical computing allowed for efficient use of limited quantum resources.

Summary of Findings

The experimental results demonstrate that the proposed Hybrid Quantum-Classical Neural Network effectively improves large-scale data classification performance. The combination of quantum feature encoding, variational quantum circuits, and classical neural networks resulted in higher accuracy, faster convergence, and greater robustness than traditional approaches. These findings suggest that hybrid quantum machine learning architectures represent a promising direction for future intelligent systems and real-world classification applications.

CONCLUSION

This study introduced a Hybrid Quantum-Classical Neural Network (HQCNN) architecture for classifying massive datasets by merging variational quantum circuits with conventional neural network designs. The solution exploited quantum computing concepts like superposition, entanglement, and quantum feature encoding to improve how data are represented and to boost classification accuracy. The approach combined data preprocessing, quantum feature encoding, design of variational quantum circuits, quantum measurement, and a classical dense-layer classifier. Experimental results showed that the HQCNN outperformed conventional machine-learning and deep-learning techniques. The system reached a classification accuracy of 98.3 %, precision of 97.9 %, recall of 98.1 %, and an F1-score of 98.0 %, while cutting training duration by roughly 21.4 % relative to a standard CNN. The findings additionally indicated that quantum-augmented feature extraction boosted the model's capacity to capture intricate patterns in high-dimensional data. Moreover, the suggested system demonstrated considerable resilience in the presence of noise, preserving high classification performance despite the injection of disturbances into the input. The mixed architecture successfully tackled existing quantum hardware constraints by merging quantum computation for feature acquisition with classical neural networks for scalable decision processes. Overall, the results show that Quantum Neural Networks possess considerable promise for enhancing classification precision, learning efficiency, and feature representation in large-scale data analytics. The proposed HQCNN framework illustrates the practical viability of employing quantum machine learning methods on real-world classification tasks and lays the groundwork for future research in quantum-enhanced artificial intelligence.

Prospective Outlook

Upcoming expansions of this work comprise:

- Execution on actual quantum devices supplied by IBM Quantum and various other quantum platforms.
- Development of deeper and more scalable quantum neural network architectures.
- Adopting quantum error correction strategies to enhance reliability.
- Implementation of the suggested model for healthcare, cybersecurity, financial forecasting, and image-recognition challenges.
- Investigation of quantum transformers and quantum deep learning architectures for large-scale AI applications.
- Study of federated quantum machine learning for privacy-preserving data analysis.
- Enhancement of qubit usage and quantum circuit complexity for practical deployment.

The study finds that hybrid quantum-classical learning frameworks offer a promising path for next-generation intelligent systems and could be pivotal in advancing quantum artificial intelligence and large-scale data analytics.

ABSTRACT

Obesity is a chronic, multi-faceted disease and pandemic in our global population, impacting cardiovascular, metabolic and oncological processes. In recent years, obesity management has undergone a revolution, with temporary weight-loss drugs like sympathomimetic agents and peripherally acting lipase inhibitors, and now, incretin drugs that produce sustained weight loss as high as 20% of the body weight. At the same time, the use of natural products and medicinal plants such as polyphenols, saponins, alkaloids and adaptogenic herbs are gaining momentum as possible additional or alternative therapeutic agents for people who are intolerant or not suitable for conventional drug use. This review covers the complete explanation of the pathophysiology and etiology of obesity, the pharmacological action and clinical profile of the available synthetic anti-obesity drugs, and the evidence-based support for some of the natural products that have been used to help manage obesity. A comparative analysis produces a structured evaluation of efficacy, safety, persistence of weight loss and long-term results of both drug classes. Therapeutic frontiers are covered, such as triple incretin agonists, amylin analogues, gut microbiome-targeted therapies, combination nutraceuticals and precision medicine strategies. In conclusion, the review suggests that a combination of pharmaceutical and plant-based interventions in an integrated, individualized approach with strong clinical evidence is the most viable option for sustainable, long-term obesity management

Keywords: pharmacotherapy, Obesity, Long-term safety, natural products, anti-obesity drugs, metabolic disease

INTRODUCTION

Obesity is a chronic condition that can be relapsing, in which there is excess body fat and is considered a world disease; the rate of obesity has risen significantly since the 1970s [10][18]. It can be characterized as having a body mass index (BMI) of 30 kg/m² or greater. In today's society, more people are obese and overweight than underweight. Obesity is a complex phenomenon and is not a direct consequence of individual's behavior but rather is driven by genetic, environmental, hormonal and metabolic factors that play a role in the development and pathogenesis [10][27]. Obesity is a serious health threat worldwide identified by the World Health Organization (WHO) and is more than tripled since 1975. Obesity is responsible for morbidity and mortality in more than 4 million people around the world every year, and associated with other life-threatening (disabling) diseases like Type 2 diabetes, cardiovascular diseases, and some cancers. In addition to adults, obesity is a growing problem in children and adolescents, leading to a serious clinical and public health problem worldwide [10][18][27].

Epidemiology

Obesity is a chronic health condition characterized by the buildup of excessive fat tissue that is prevalent worldwide since the late-1990s. It has increased rapidly in both adults and children, irrespective of economic development among people in regions. According to various surveys, over the past 20 years, the prevalence of obesity among adults in high-income countries like the USA has increased from around 30.5% to more than 42% in 2018, and longitudinal analyses suggest a further rise into the current decade [10][22]. New conditions of socioeconomic status, urbanization, diet and a sedentary lifestyle have fueled the epidemic in low and middle-income nations [11][13].The high incidence of obesity is closely related to the rise in non-communicable diseases (NCDs), such as type 2 diabetes, cardiovascular diseases, and different types of cancers, highlighting its primary position in the worldwide declining health scenario. Epidemiological research shows that factors within the environment play a major role in driving obesity in not only humans, but also in other species, such as companion animals, and that shared environmental factors account for more than just human behaviour [18][25]. New global data published recently indicate that countries in the Pacific Islands, the Middle East and North Africa are likely to have the highest age-standardized rates if the current trends continue [11][22].

Pathophysiology of Obesity

Obesity clinical manifestation is a result of the interaction between genetic, environmental, neuroendocrine, immunometabolic and microbial signals that drive energy imbalance, and eventually result in chronic disease and multisystem comorbidity [4][15][24][25]. The continuous excessive intake of calories causes enlargement and proliferation of adipocytes, increasing the size of white adipose tissue (WAT), which results in excess visceral fat and abnormal lipid deposition within the organs, such as the liver, muscle and heart. Adipose tissue is an endocrine organ and produces adipokines such as leptin, resistin and adiponectin, besides pro-inflammatory cytokines like TNF-α and IL-6, which result in a continuous inflammatory state typical of obesity.

Adipose Tissue and Inflammatory Mechanisms

White Adipose Tissue (WAT) stores energy, and brown adipose tissue (BAT) burns energy through adaptive thermogenesis with the help of uncoupling protein-1 (UCP1). The "browning" of WAT is a metabolically protective events that is inhibited by inflammation in obesity. When the body expands the adipose tissue, it increases the production of pro-inflammatory mediators, which causes the immune microenvironment to shift toward the pro-inflammatory M1 phenotype, which will increase inflammation in the adipose tissue and throughout the body [24].

Interplay of Inflammation, Oxidative Stress, and Insulin Resistance

Insulin resistance is caused by chronic inflammation and oxidative stress. The secreted free fatty acids from dysfunctional adipose tissue contribute to the development of type 2 diabetes by being involved in several key

processes, including: Lipotoxicity, activation of pro-inflammatory signalling pathways (e.g., JNK, NF-κB) and effects on insulin action in muscle, liver and adipose tissue [4][15]. The disruption of the insulin signalling mechanism in adipocytes is also exacerbated by generation of reactive oxygen species from the dysfunctional mitochondria, which in turn contributes to endothelial dysfunction associated with cardiovascular risks[9][24].

Adipokine Imbalance and Genetic-Epigenetic Regulation

Two important adipokines, leptin and adiponectin, are significantly disrupted in obesity. Hyperleptinemia and leptin resistance, together with low levels of adiponectin, lead to a disturbance in energy homeostasis, over-increase inflammation, and decrease insulin sensitivity. Both genetic variations in the leptin-melanocortin pathway (which involve mutations of LEPR, POMC, MC4R and PCSK1) and epigenetic changes, including CpG methylation of appetite and metabolic genes, affect both susceptibility to obesity and to pathological consequences of obesity [4][9][25].

Neuroendocrine Mechanisms in Appetite Regulation

Obesity pathogenesis involves a neuroendocrine dysfunction. Leptin and insulin resistance in the hypothalamus, normal disruption of gut hormones such as ghrelin, peptide YY (PYY) and GLP-1, and disruption of the neuronal circuits in the arcuate nucleus and lateral hypothalamus disrupt appetite and satiety regulation [4][24]. Biological mechanisms that motivate hyperphagia (the drive toward increased eating) exist through interactions between central dopaminergic and opioidergic reward pathways and homeostatic pathways which behavioral interventions are not enough to counteract. This neuroendocrine environment becomes more and more pharmacological target.

Gut Microbiota-Mediated Metabolic Inflammation

The gut microbiota is a critical regulator of energy harvest, lipids storage and metabolic inflammation. Microbial changes lead to increased caloric extraction, increased intestinal permeability ("leaky gut"), translocation of lipopolysaccharide and systemic pro-inflammatory signalling, with an increased *Firmicutes:Bacteroidetes* ratio and reduced microbial diversity (dysbiosis). The production of short-chain fatty acids (SCFAs) by gut microbiota directly influences satiety hormone release (GLP-1 and PYY) and energy balance [4][15][25].

Ectopic Fat Accumulation and Organ Dysfunction

Obesity causes ectopic fat deposition in the liver (non-alcoholic fatty liver disease/NAFLD), myocardium (pericardial fat) and skeletal muscle (intramyocellular lipid) and leads to organ dysfunction locally and systemically. In susceptible individuals, hepatic steatosis leads to steatohepatitis, fibrosis and cirrhosis. Atherosclerosis, dyslipidaemia and hypertension are all cardiometabolic risks which are mainly driven by visceral adiposity, compared to subcutaneous fat, which is far more metabolically active [15][24].

Etiology of Obesity

Obesity is a complex disorder that has both non-modifiable and modifiable risk factors. Non-modifiable factors involve genes - monogenic (defects in leptin-melanocortin signalling), polygenic susceptibility (additive effects of hundreds of common variants) and syndromic obesity (e.g. Prader-Willi and Bardet-Biedl syndromes) - and epigenetic modification related to in utero and early-life exposures. Further non-modifiable aetiologies are hypothalamic injury due to tumour or trauma or irradiation to the brain. Modifiable contributors include physical inactivity, excess calorie consumption and the obesogenic food environment of energy-dense, ultra-processed foods. Factors associated with elevated risk for obesity in the future include exposures during pregnancy such as maternal obesity, gestational diabetes, excessive infant weight gain, low breastfeeding duration, sleep deprivation, and early solid food introduction. Secondary obesity is caused by medical conditions (hypothyroidism, Cushing's syndrome and polycystic ovary syndrome) and medications (antipsychotics, glucocorticoids and insulin). Organotins, DDT and bisphenol A (BPA) are examples of chemicals that have been identified to induce adiposity, especially at critical developmental stages [19].

Established Synthetic Anti-Obesity Drugs

Pharmacological therapy for obesity has come a long way in the last 20 years, from the use of mainly short-term appetite suppressants to the development of potent long-term agents with an effect on various aspects of metabolism. Orlistat, phentermine-topiramate, naltrexone-bupropion, liraglutide, semaglutide, tirzepatide, and setmelanotide (for genetic obesity) are current FDA- and EMA-approved drugs used for chronic weight management [1][8][20].

Centrally Acting Appetite Suppressants

Phentermine and its derivatives (diethylpropion, benzphetamine, phendimetrazine) are members of the sympathomimetic amine class of drugs—the oldest drugs used for short-term weight loss. Their mechanism of action is through stimulating the release of norepinephrine in the hypothalamus, which results in reduced appetite and increased expenditure of energy. The two active ingredients in the combination formulation phentermine-topiramate ER (Qsymia) work together in additive ways: Topiramate is a GABA-agonist and carbonic anhydrase inhibitor that increases satiety and weight loss of about 8-10% from baseline. However, due to the safety issues such as insomnia, hypertension, palpitation and teratogenicity, patient selection and monitoring is critical.Limited use: Phentermine alone is usually used for a few weeks; Contraindicated: Cardiovascular disorders, history of substance misuse [1][8][20].

Peripherally Acting Lipase Inhibitors

Orlistat (Xenical prescription, Alli over the counter) is a non-systemic pancreatic and gastrointestinal lipase inhibitor that acts by preventing the absorption of dietary fat by ~30%. It has been approved for short-term and long-term obesity treatment as part of the low-fat, low-calorie diet. The action mechanism of orlistat leads to an increased amount of fat being excreted in faeces which decreases calorie consumption. The XENDOS trial was a landmark study showing that over 4 years orlistat and lifestyle modification slowed the onset of type 2 diabetes by 37.3% as compared to placebo. Although gastrointestinal side effects (oily stools, faecal urgency, steatorrhoea) are generally well tolerated, fat soluble vitamin (A, D, E, K) deficiencies occur frequently and require dietary advice and multivitamin supplementation [1][8][20].

Central Mechanisms of Bupropion-Naltrexone

This is a combination drug (Contrave, Mysimba in EU) that contains bupropion, a norepinephrine and dopamine reuptake inhibitor, and naltrexone, an opioid receptor antagonist. This dual mechanism acts on two distinct areas of the brain: hypothalamus (satiety induced by activation of POMC neurons) and brain reward system (craving reduction through opioid pathway blockade) leading to an increased feeling of satiety and decreased compulsive eating. The COR (Contrave Obesity Research) clinical trial programme showed a mean loss of ~5–6% weight over placebo. Side effects include nausea, headache, and elevated blood pressure, and the combination is contraindicated in patients with history of seizure disorders and uncontrolled hypertension, and should be titrated gradually for improved tolerability [1][20][28].

Serotonin Receptor Modulators

Previously, pharmaceuticals like lorcaserin (selective 5-HT2C serotonin receptor agonist, Belviq) had been used to inhibit appetite by stimulating POMC neurons in the hypothalamus. In 2020, the FDA removed Lorcaserin from the market because of a higher risk of malignancy seen in the cardiovascular outcomes trial, CAMELLIA-TIMI 61. In the past, fenfluramine containing compounds (fen-phen) were withdrawn from the market due to serious side effects of valvular heart disease and primary pulmonary hypertension. While this class is not presently available, it illustrates the continuing issue of cardiovascular safety with centrally acting anti-obesity drugs [1][20].

GLP-1 Receptor Agonists

The GLP-1 receptor agonists (GLP-1 RAs) are the most major breakthrough in a century in obesity pharmacotherapy. Liraglutide (Saxenda, 3.0 mg daily subcutaneous) and semaglutide (Wegovy, 2.4 mg weekly subcutaneous) are

structurally similar to the endogenous incretin hormone GLP-1, and act on GLP-1 receptors in the hypothalamus to increase satiety, reduce appetite, delay gastric emptying and improve glycaemic control. The SCALE Obesity trial has shown about 8% weight loss with liraglutide, and the landmark STEP 1 trial has revealed a 14.9% mean loss of body weight compared to 2.4% with placebo over 68 weeks with semaglutide 2.4 mg. The SELECT cardiovascular outcomes trial also reinforced the finding that semaglutide 2.4 mg lowers the major adverse cardiovascular events in obese adults without diabetes who have established cardiovascular disease - a paradigm-shifting extension to the indication for weight loss alone. The oral semaglutide treatment (Rybelsus, 7–14 mg a day) has enhanced availability and could potentially further boost adherence in groups who prefer not to inject, whereas the anti-obesity indication has been at higher doses of oral semaglutide (OASIS trial) and is currently undergoing regulatory assessment. The newer dual agonists (e.g. tirzepatide, GIP/GLP-1 dual agonist, Mounjaro/Zepbound) have shown about 20–22% total weight loss in the SURMOUNT programme, significantly outperforming the established GLP-1 monotherapy.Triple agonists like retatrutide (GLP-1/GIP/glucagon) are also moving forward to Phase 3, featuring even more potent signals for weight loss [1][20][28][29].

MC4 Receptor Agonists

Setmelanotide (IMCIVREE) acts as a melanocortin-4 receptor (MC4R) pathway agonist, and is FDA approved for rare, inherited obesity caused by genetic mutations of POMC, LEPR, or PCSK1. Unlike other treatments, there are no medications that directly restore impaired melanocortin signalling in the hypothalamus. setmelanotide is the first drug to do so, and as a result it can induce significant and prolonged weight loss in the populations that have been studied in Phase 3 trials (which tend to be rare populations) - average of 25% or more - but isn't indicated for the polygenetic or common obesity patient population. Injection site reactions and reversible hyper pigmentation (MC1R agonism) are side effects [1][20][28].

Role of Natural Products and Medicinal Plants in Obesity

Plant-based compounds used to combat excess weight and metabolic diseases have been a part of traditional medicine systems, such as Ayurveda, Traditional Chinese Medicine (TCM), and indigenous pharmacopoeias in Asia, Africa, and the Americas for a long time. These ethnobotanical leads have been the focus of scientific investigation and have revealed several bioactive phytochemicals with known anti-obesity activity mechanisms such as enzyme inhibition, suppression of adipogenesis, enhancement of thermogenesis, modulation of gut microbiota, and central appetite regulation [2][3][21]. The most well documented natural agents are examined in the following section.

Platycodon grandiflorum

The root of *Platycodon grandiflorum* contains a high concentration of triterpenoid saponins, known as platycodins, which have strong pancreatic lipase inhibitory activity, leading to decreased dietary fat absorption and hence caloric consumption with increased faecal fat excretion. Other research indicates platycodins also regulate inflammatory pathways and help to enhance serum lipid profiles. The extracts from the root of the balloon flower have been used in traditional medicine in East Asia for metabolic and respiratory disorders, and therefore, it is a prominent ethnobotanical candidate for weight management [21].

Panax ginseng

A number of species of the genus Panax forms the backbone of traditional medicine in Asia. The ginsenosides have been reported to inhibit fat absorption through the inhibition of pancreatic lipase and to lower the adipogenesis through the down regulation of PPARγ and other transcription factors in adiposet issues. Ginseng extracts have demonstrated effects in animal models and in certain clinical studies to enhance glucose metabolism and to decrease visceral fat accumulation. Moreover, ginseng regulates immune and inflammatory responses which can play a role in the prevention of chronic diseases associated with obesity [3][21].

Green Tea (Camellia sinensis)

Green tea is the most widely studied botanicals against obesity. The main bioactive polyphenols of it, epigallocatechin gallate (EGCG) and related catechins, inhibit pancreatic lipase and α-amylase, respectively, which hinders fat and carbohydrate breakdown. Besides the decreased absorption of macronutrients, green tea has been shown to raise energy expenditure through enhanced thermogenesis through activation of BAT (adrenergic stimulation and UCP1 upregulation) and to induce fat oxidation during exercise. In 2022, a meta-analysis of 27 randomized controlled trials (RCTs) found a moderate but significant weight loss of about 1.31 kg compared to placebo when taking catechins. In 2022, a meta-analysis of 27 randomized controlled trials (RCTs) also revealed that catechins led to moderate but statistically significant weight reductions, approximately 1.31 kg compared to placebo. Green tea also offers antioxidant and anti-inflammatory properties that can enhance metabolic health among obese people. Importantly, high dose EGCG supplements (more than 800 mg/day) have been found to be hepatotoxic in sensitive populations, and dose-specific monitoring of safety is recommended [12][21].

Gardenia jasminoides

Fruit of *Gardenia jasminoides* is used traditionally in Chinese medicine for metabolic diseases. Crocin and crocetin are active compounds that act on pancreatic lipase and inhibit its activity, in a similar way as or list at does, but with a lower incidence of gastrointestinal side effects. Gardenia extracts are also anti-inflammatory, lowering serum triglycerides and possibly down regulating hepatic lipogenic gene expression. Studies in animals have consistently shown better body weight and body weight indicators after gardenia treatment; strict human clinical studies are limited[21].

***Curcuma longa* (Turmeric)**

The main polyphenol in *Curcuma longa* (Turmeric) has a broad-spectrum anti-inflammatory and anti-adipogenic profile – curcumin. Curcumin inhibits adipocyte differentiation and proliferation by inhibiting PPARγ and CCAAT/enhancer-binding proteins (C/EBPs), and UCP1 is also increased in BAT, increasing energy expenditure. In rodent diet-induced obesity models, curcumin lowered body fat mass, enhanced insulin sensitivity and downregulated the mRNA expression of the inflammatory markers such as tumor necrosis factor alpha, IL-6, and resistin in adipose tissue. Its extensive use in food makes turmeric safer to be consumed, although the bioavailability of curcumin of turmeric is very low in the intestine (<1%). Some formulation approaches are being explored to increase the therapeutic level of curcumin such as nanoparticles, phospholipid complexes and co-administration with piperine [2][21].

***Capsicum annuum* (Chili Pepper)**

The compounds capsaicin and capsiate from *Capsicum annuum* activate the transient receptor potential vanilloid 1 (TRPV1) which is a channel in the SNS that increases thermogenic fat oxidation and reduces appetite. These effects are equivalent to a measurably increased metabolic rate (around 4-5%) and cumulative reduction in intake of calories in clinical studies. Capsicum also helps to prevent adipocyte differentiation and regulates gut hormones that help regulate feelings of appetite, such as leptin and ghrelin. Twenty trials were used in a meta-analysis and it was concluded that capsinoids could effectively reduce body weight and abdominal fat when compared with placebo. Regular chili consumption is also associated with reduced prevalence of obesity in several Asian and South American populations, in accordance with the epidemiological data [17][21].

Garcinia cambogia

The rinds of the *Garcinia cambogia* fruit contain high levels of (-)-hydroxycitric acid (HCA), a competitive inhibitor of ATP-citrate lyase, the rate-limiting enzyme in the cytosol which converts acetyl-CoA to fatty acid. This also decreases the production of fat and the amount of fat stored in the body, and increases the production of glycogen in the liver. HCA also acts on serotonin release, which decreases appetite and maintains compliance with a hypocaloric diet. In a systematic review of 12 RCTs, a small but statistically significant mean weight difference of ~0.88 kg was reported versus placebo. The differences in outcomes are due to the differences in the content and formulation of the

commercial HCA products. There are rare reports of hepatotoxicity with high doses, thus proper dosing guidelines are required [21][23].

Griffoniasimplicifolia

Seeds of *Griffoniasimplicifolia* are a natural source of 5-hydroxytryptophan (5-HTP), the immediate precursor to serotonin. 5-HTP supplementation causes earlier meal termination and lower food intake by increasing the availability of central serotonin which leads to increased signal transduction through 5-HT2C receptors in the hypothalamus, similar to the effect of the withdrawn drug lorcaserin, but endogenously. Moreover, 5-HTP can also reduce stress-induced eating and emotional hunger by serotonergic modulation of mood making the plant relevant for obesity due to psychosocial factors. Doses of 100-300mg taken three times a day have been shown to decrease carbohydrate intake and to achieve moderate amounts of weight loss in overweight people through clinical trials. Supplements are generally safe to take, although there may be a risk of serotonin syndrome in those who are taking other serotoninergic drugs [5][21].

***Phaseolus vulgaris* (White Bean Extract)**

Common bean (*Phaseolus vulgaris*) contains phytohaemagglutinin and α-amylase inhibitors which compete for the pancreatic α-amylase, reducing the degradation of starch and the postprandial glucose uptake. This allows the postprandial glucose to rise less, reducing the insulin storage of fat, and ultimately making the individual more sensitive to insulin.Standardized white bean extracts (Phase 2) have been found to reduce body weight, fat mass and waist circumference in clinical trials with a calorie-controlled diet. The beans have also high levels of resistant starch and soluble fibre, which can help to regulate appetite and promote gut health via the gut microbiome [5][21].

Caralluma fimbriata

Caralluma fimbriata is a succulent plant eaten as food in rural India during times of famine that acts on central satiety pathways to suppress appetite, likely by activating the hypothalamic AMP-kinase signaling pathway, but not by inhibiting digestive enzymes. Clinical and pre-clinical studies show that the compound decreases food consumption, body fat content, and weight loss in 12 weeks; further studies suggest that the compound inhibits adipocyte differentiation by modulating adipogenic genes such as PPARγ. A systematic review showed that waist circumference decreased significantly when treated with Caralluma. It has been used in diet for a long time in India, which gives a sense of its safety [6][21].

Ganoderma lucidum

The anti-obesity effects of polysaccharides and triterpenes from *Ganoderma lucidum* (reishi mushroom) are mainly mediated by modulating gut microbial composition, increasing the gut barrier integrity and decreasing the endotoxaemia and systemic inflammation. In a ground-breaking preclinical study, the Ganoderma polysaccharides reversed high-fat-diet-induced obesity plus metabolic syndrome phenotypes in mice through the microbiome pathway. Ganoderma's potential in obesity is supported by a strong preclinical track record, as well as safety as a dietary supplement in Asia, leading to the continuation of clinical trials in humans that relate to obesity, mediated by the gut-microbiome[7][16][21].

Comparative Analysis of Synthetic Drugs and Natural Products

The synthetic and comparative analysis of anti-obesity drugs and natural products show that there are significant differences in each drugs' effectiveness, mechanism of action, safety, clinical evidence, cost, and availability. These differences are relevant in clinical practice in selecting treatments.

Extent of Weight Loss and Treatment Efficacy

The largest randomized controlled trials consistently show superior and clinically meaningful weight reduction with synthetic anti-obesity drugs, specifically GLP-1 receptor agonists. Semaglutide 2.4 mg results in around 14.9–17.3% total body weight loss (TBWL); approximately 20–22% TBWL with tirzepatide; and 3–6% more with older agents,

including orlistat and naltrexone-bupropion compared with placebo [14][29]. Natural products, on the other hand, usually yield 0.5-3% TBWL in strict clinical trials and green tea catechins, capsaicin and white bean extract are most effective. For people with mild to moderate obesity or metabolic risk, however, natural products can provide some effective weight loss in a context where cost of drugs and/or side effects restrict their use [12][23].

Similarity and Difference in Mechanisms of Action

The two classes of drugs act on similar, but different, biological pathways. Some natural ingredients (Platycodon, *Panax ginseng*, *Gardenia jasminoides*, green tea) have the same mechanism of pancreatic lipase inhibition, which could have additive effects. The neuroendocrine satiety signalling pathways targeted by GLP-1 RAs (semaglutide, liraglutide) are similar to those targeted by natural appetite suppressants such as 5HTP (*Griffoniasimplicifolia*) and *Caralluma fimbriata*, but they are less potent. Natural products like curcumin, capsaicin, and Ganoderma target metabolic inflammation and gut microbiota, which are just starting to be targeted by new synthetic drugs. The diversity of the mechanisms indicates that combination strategies that target multiple pathways at the same time might be particularly potent.

Safety and adverse effect profiles

Synthetic drugs that have been approved for long-term use have adverse effect profiles proven through large clinical programmes.Gastrointestinal effects (nausea, vomiting, diarrhoea) are seen in 30-40% of patients taking GLP-1 RAs and pancreatitis and thyroid C-cell hyperplasia are rare in rodents but human risk is unconfirmed. Sympathomimetics have cardiovascular side effects and are teratogenic. A number of drugs in this class have been removed from the market due to the emergence of post-marketing safety signals (sibutramine, lorcaserin, rimonabant), raising the long-term safety concerns with centrally acting agents. The acute safety of natural products is good at recommended doses. Green tea EGCG and *Garcinia cambogia* have hepatotoxicity risks, which are mainly at high doses. Capsaicin can irritate the gut in susceptible persons and/or at high doses; 5-HTP can induce serotonin syndrome in susceptible persons or at high doses. Most importantly, the follow up durations for natural products are short, the sample sizes small, and the pharmacovigilance is not as strong as in the case of synthetic drugs, which can lead to the underestimation of rare adverse effects [1][20].

Long-Term Safety of Anti-Obesity Treatment

Since obesity is a chronic condition that requires long-term management, long-term safety is a key component of the clinical usefulness of any anti-obesity intervention. The safety profile of anti-obesity drugs – natural and pharmaceutical – has undergone significant changes over the last few decades, driven by post-marketing surveillance, cardiovascular outcomes trials and real-world evidence. The early obesity medications were known to have dangerous side effects on the heart. Fenfluramine and dexfenfluramine were associated with valvular heart disease and primary pulmonary hypertension; sibutramine was withdrawn following the SCOUT trial, which showed that high-risk subjects had more cardiovascular events; and, rimonabant was withdrawn because of psychiatric side effects such as suicidality. In the current regulatory landscape, cardiovascular outcome trials (CVOTs) are required for any new anti-obesity drug. In obese adults with established cardiovascular disease, SELECT showed 20% reduction in MACE, marking a new benchmark for cardiometabolic benefits. The XENDOS trial of or list at was successful, with an 37.3% diabetes incidence reduction found with no concerning cardiac signals [20]. The most frequently reported class effect of GLP-1 receptor agonists is gastrointestinal adverse effects, which can occur in up to 40–50% of patients, especially when stepwise up-titration is occurring.

Nausea, vomiting and diarrhoea usually improve in 4–12 weeks. There are rare but serious gastrointestinal effects such as pancreatitis, ileus, and potentially a slightly higher risk of aspiration pneumonia in surgical patients who have not stopped GLP-1 RAs before surgery (emerging PV signals). The gastrointestinal side effects of orlistat (oily stool and faecal urgency) are well documented and are lessened with the use of a low-fat diet. Educational recommendations are very important: natural products like green tea at high doses, and *Garcinia cambogia* have been linked with rare hepatotoxicity cases [20]. Centrally acting agents are inherently psychotropic in nature. Naltrexone-

bupropion has black-box warnings for risk of suicidality associated with bupropion (based on warnings for antidepressant drugs). It is important to monitor for cognitive side effects from topiramate in patients with phentermine-topiramate. The cardiovascular outcomes trial CAMELLIA for lorcaserin had cancer signals that resulted in a withdrawal. There are no psychiatric warnings given in the class product characteristics information, although there are some ongoing pharmaco vigilance reports concerning the occurrence of suicidal ideation and self-harm, with initial analyses of these reports suggesting a low risk for these conditions which is subject to further investigation by the EMA and FDA that needs larger, longer datasets.

High efficacy GLP-1 RAs and surgical interventions for weight loss can result in significant and rapid body weight loss that can lead to non-trivial reductions in lean body mass and bone mineral density, especially in older individuals and post-menopausal women. The concerns for long-term semaglutide treatment and its impact on sarcopenic obesity came from the STEP 5 trial, which showed more lean mass loss than fat mass. Pharmacotherapy is recommended to be supplemented with sufficient protein, resistance and calcium/vitamin D intake to reduce musculoskeletal risks [1][20].The safety of natural products as anti-obesity supplements is generally established based upon their long history of culinary and traditional medicinal purposes, and use at recommended dosage levels. But there are some safety issues to consider. Higher doses of green tea EGCG have been linked to liver damage caused by its use as a drug. In case reports, high doses of garcinia cambogia have been associated with hepatotoxicity. Capsaicin has been found to irritate the gut. *Griffoniasimplicifolia* (5-HTP) may cause serotonin syndrome when combined with MAOIs, antidepressant medications, and triptans. In most countries, the regulation of herbal products is much less stringent than that of pharmaceuticals, leading to a higher risk of adverse effects due to adulteration, mislabelling and inconsistent dosing[3][21][29].

Sustainability of Weight Loss

One of the most important and difficult problems in the management of obesity is the sustainability of weight loss gained from anti-obesity interventions. Weight loss is highly challenging and difficult to maintain in the long term without the use of lifestyle modification because biological and behavioural counter-regulatory mechanisms counteract weight loss.

Weight Regain After Discontinuation

One of the major difficulties associated with the status quo pharmacotherapy is the significant weight gain associated with stopping treatment. STEP 4 extension trial results showed that participants who discontinued the 2.4 mg dose regained about 2/3 of lost weight over 1 year, which was similar to the placebo group body weight, while the pattern was the same for liraglutide, reinforcing why obesity is a chronic relapsing disease that should be treated chronically. These data fundamentally change the paradigm of anti-obesity drugs and, like antihypertensive and lipid-lowering medications, warrant lifelong use and have a significant impact on the duration, cost and counselling of treatment [26].

Factors Predicting Long-Term Weight Loss

Early response (weight loss > 5% by 12-16 weeks), intensity of lifestyle intervention and weight promotion comorbidities and medications are factors associated with maintaining weight loss. Those patients who use drugs together with physical activity and diet programs clearly and more consistently find both to be more effective and long lasting than either using diet or exercise programmes alone. Psychological factors such as food addiction, emotional eating behaviours, insomnia and socioeconomic factors influence whether or not long-term success will be achieved and need to be purposefully targeted via multidisciplinary care pathways [10].

Natural products and weight loss durability

The long-term effects of the use of natural products for weight loss are far less known when compared to synthetic drugs. The majority of clinical trials with natural anti-obesity agents have lasted for 8–24 weeks and a few studies have been conducted for more than 6 months. The slight weight reductions of natural products (usually 1–3 kg) are

easily reversible with their withdrawal. Other natural factors (e.g., dietary fibre sources (Phaseolus vulgaris, resistant starch), capsaicin and gut microbiota-modulating interventions (Ganoderma)) may have more enduring physiological effects, either by inducing structural remodeling of gut microbiome composition, influencing set points related to appetite hormones, or inducing thermogenic adaptations. A research priority is long-term trials that are specifically designed to test weight loss maintenance with natural products [3][21].

Combined Interventions for Long-Term Outcomes

There is growing evidence that supports the idea of pairing pharmacological therapies with natural products to improve efficacy and sustainability of weight loss. These complementary effects of GPL-1 RAs (central satiety and glycaemic control) and the natural products (lipase inhibition, green tea; thermogenesis, capsaicin and curcumin; gut microbiome health, Ganoderma and prebiotic fibres) have potential to provide additive or synergistic benefits. Formal combination trials, however, do not exist and drug-botanical interactions of note (e.g., drug effects on the metabolism of green tea through the use of CYP enzymes) must be considered before combining these in clinical practice [21].

Emerging Directions

There is an unprecedented level of innovation in the field of anti-obesity therapeutics, with deep mechanistic understanding of how obesity is driven by neuroendocrine, microbiome and genomic factors, along with the clinical success of incretin-based therapeutics. The following merging fields are especially poised to revolutionize obesity treatment in the next decade.

Next-Generation Incretin Therapies

A new generation of multi-target incretin agonists are progressing through late-stage clinical development following the success of semaglutide and tirzepatide. In Phase 2, up to 24% mean weight loss at 48 weeks has been shown, which is better than any other previous pharmacological weight loss intervention and is closer to the results of bariatric surgery. Other combination products are in late development, including Cotadutide (GLP-1/glucagon dual agonist) and cagrilintide (long-acting amylin analogue) with a small-molecule GLP-1 receptor agonist (CagriSema). Non-peptide oral GLP-1 receptor agonists, such as orforglipron and danuglipron, have the transformative potential of pill-based incretin therapy and can have a significant impact on global accessibility [14][20].

Gut Microbiome-Targeted Therapies

Given the gut microbiome's critical involvement in energy metabolism, inflammation, and satiety hormone regulation, it is a top target for therapeutic intervention. In proof-of-concept studies, faecal microbiota transplantation (FMT) involving lean donors has been shown to have metabolic advantages. Specific changes to microbial consortia, specifically SCFA-producing bacteria like *Akkermansiamuciniphila*, are being studied.Efforts to identify the anti-obesity effects of Ganoderma lucidum and other natural products that restore gut microbial diversity could be used to develop new pharmacological agents that target the microbiome. A future application of microbiome profiling is integrating the data into personalised obesity management algorithms [7][20].

Adipose Tissue-Targeted and Thermogenic Approaches

Therapeutic measures to boost BAT thermogenesis and induce WAT "browning" offer a major unexploited potential to boost REE. Thermogenic agents are being explored such as beta-3 adrenoreceptor agonists (mirabegron), thyroid hormone receptor-beta agonists (resmetirom, already approved for NASH) and fibroblast growth factor 21 (FGF21) analogues. Low dose adjuvants may include natural substances that activate BAT, including capsaicin, curcumin and EGCG. A novel pathway for drug discovery of novel brown adipocyte differentiation regulators derived by high throughput screening of natural product libraries is suggested [15][24].

Precision Medicine and Pharmacogenomics

There is significant inter-individual response to anti-obesity therapies that is not well predicted by clinical phenotypes. Variants in the GLP-1R, MC4R, FTO or related genes may undergo pharmacogenomic profiling to identify the patients likely to be good responders to particular classes of drugs. Multi-omic platforms, combining genomics, metabolomics, gut microbiome analysis and continuous glucose monitoring, are now starting to allow for the personalised selection of obesity treatments. This precision phenotyping of obesity subtypes (hyperphagia-predominant, hedonic eating-predominant, metabolic inflammation-predominant, and circadian dysregulation-predominant) may be useful in providing a better match of treatment beyond one-size-fits-all algorithms in the future [4][25].

Nutraceutical–Drug Integration for Obesity Management

The synergistic potential of multi-component nutraceuticals, comprised of several complementary natural ingredients like EGCG, capsaicin, curcumin and Phaseolus vulgaris extract, may enhance their mild effects and induce clinically significant weight loss with a good safety profile. Promising pharmacological mechanisms of the natural compounds can only be translated to therapeutically useful products with the assistance of bioavailable technologies, such as the structured lipid emulsions, phospholipid complex formation and nanoencapsulation. Research on drug-botanical interactions, especially with regards to CYP450 enzyme modulation, induced by green tea, curcumin, and Ganoderma are required to safely combine natural products with pharmaceutical agents [21].

CONCLUSION

Obesity is one of the most prominent public health issues of the 21st century as a consequence of various factors including genetic susceptibility, environmental stressors, neuroendocrine disruption, disruption of gut microbiome and socioeconomic factors. The introduction of GLP-1 receptor agonists, especially semaglutide and tirzepatide, has revolutionized the therapeutic options available for weight loss, effectively mimicking the effects of bariatric surgery, and has shown benefits for the cardiovascular and renal system that are far beyond its weight-loss effects. These drug discoveries provide a scientific basis to recognize obesity as a treatable chronic condition and not a problem of personal responsibility. At the same time, herbal remedies and drugs from nature provide a scientifically supported, mechanism rich and relatively safe complementary approach to obesity control. The active ingredients of green tea catechins, capsaicin, curcumin, 5-HTP and *Caralluma fimbriata* have different ways of blocking pancreatic enzymes, thermogenesis, central satiety circuits, and adipogenesis than synthetic drugs. Their effects in individuals are small and similar to those of pharmaceuticals, but their impact is increased due to their reach, low cost, and long safety records, as well as their relevance to integrative and culturally congruent care models and to low-income and low-resource settings where GLP-1 RAs are not financially accessible.

A comparison of efficacy, safety, evidence, and sustainability shows that synthetic and natural anti-obesity agents are not mutually exclusive but complementary elements of a multi-tiered approach to treating obesity. Natural products can be used as adjuncts, as bridges or as primary treatments for people with lower risk and/or for those who may not be able to afford pharmacotherapy, while high-risk individuals with significant obesity-related comorbidities should consider pharmacotherapy with a drug proven to be effective. The future is precision-phenotyped patient selection, multi-target combination approaches, microbiome-informed interventions and equitable access strategies ensuring that the benefits of the modern obesity therapeutics are accessible to everyone that needs them. In conclusion, a societal-wide commitment is needed beyond pharmacology: to the availability of ultra-processed food, urban design, socioeconomic inequality, and the obesogenic environment to help manage the obesity pandemic sustainably. If successful, at the population-level reductions in the obesity burden are to be realised, then these pharmacological and natural product innovations need to be placed within this wider ecological and policy frame.

ABSTRACT

Anger in preoperative patients experiencing delayed surgical procedures is a significant yet under-recognised neuro-psychiatric response that can adversely influence perioperative physiology and outcomes. This systematic review aims to synthesise current evidence on the pathophysiology, clinical manifestations, and postoperative implications of anger in the context of surgical delays, and to highlight potential assessment and management strategies. Preoperative delays intensify uncertainty, loss of control, and perceived threat, thereby amplifying anger and anxiety, which activate the sympathetic nervous system and hypothalamic–pituitary–adrenal axis, leading to elevations in blood pressure, heart rate, stress hormones, and inflammatory mediators. These psychophysiological changes are associated with poorer surgical outcomes, including heightened postoperative pain, greater analgesic requirements, sleep disturbances (particularly insomnia), and increased risk of cardiovascular and neurocognitive complications, especially in patients with comorbid conditions such as hypertension, diabetes, and cerebrovascular disease. Although preoperative anxiety has been extensively linked to adverse postoperative events, direct prospective data isolating anger remain limited; however, convergent mechanistic and observational findings support its role as an independent risk marker. The review identifies major evidence gaps, including heterogeneity in anger measurement, insufficient adjustment for psychosocial confounders, and a lack of longitudinal data on the dose–response effects of short- versus long-term delays. Clinically, the findings support integrating routine assessment of anger and anxiety into preoperative pathways, improving communication and expectation management around

delays, and implementing brief psychological interventions (e.g., CBT, relaxation and anger-management strategies) as forms of "emotional prehabilitation" to modulate sympathetic activation and improve recovery. Future research should prioritise validated anger-specific tools, robust prospective designs, and targeted interventions to clarify causal pathways and to embed emotional risk modification as a standard component of perioperative care.

Keywords: perioperative physiology, pathophysiology, neurocognitive complications

INTRODUCTION

Delays in surgery are disruptive occurrences within a healthcare system that produce increased stress for patients and negative emotions. Of these emotions, anger in particular is important because of its possible neural and physiological effects. This review seeks to amalgamate (mixing/merging) extant evidence regarding the pathophysiology of anger in preoperative patients experiencing delays and its impact on patient outcomes. Emotional and mood disorders following a stroke are common and can take many different forms. The most well-known of them is post-stroke depression. Even though there's less research on it, post-stroke anger (PSA) can happen just as often as depression does. PSA symptoms include being impatient, impulsive, confrontational, and less bearable to family members, as well as overtly violent acts (such as punching or injuring people).Moreover, contempt or seethe may moreover be a hazard calculate or trigger for stroke. The negative impacts of outrage might be reduced by other chance variables like tall blood weight or diabetes. Up to 80% of cases listed for surgery experience preoperative anxiety and emotional torture, which pose significant challenges in surgical care[**1**].The variability of anxiety intensity markedly differs among individuals and is generally linked to a diverse array of factors: sociodemographic elements, including gender, age, and level of education; psychosocial determinants, such as initial anxiety levels, psychiatric comorbidities, personality characteristics, social support networks, and coping strategies; in addition to aspects related to the specific medical condition that warrants surgical intervention, the likelihood of postoperative complications, the anesthesia technique utilized, and the degree of preoperative information communicated [**2**].Surgical procedures and general anaesthesia continue to stand as two of the most traumatic occasions in a patient's encounter [**3**], characterized by three significant and adverse elements: the dread of uncertainty, the perception of illness, and the potential for life-threatening complications [**4**].

Wrathfulness is a neurological response to preoperative stressors that has received lower attention than worry and sweat, even though it is just as significant, especially when cases have surgical complications. The intricate connections between the central nervous system, endocrine pathways, and cerebral variables that uphold wrathfulness in preoperative situations are part of the neurobiological mechanisms that can have a major impact on recovery and case issues. Conflation of substantiation wrathfulness's Neurobiological Mechanisms in Preoperative environment the actuation of the thoughtful apprehensive framework the thoughtful anxious system is significantly actuated during the preoperative phase, as substantiated by elevated blood pressure, heart rate, and release of stress hormones. All organ systems exhibit physiological responses as a result of epinephrine and norepinephrine stimulation, which constitutes the body's initial stress response [**5**]. Surgical Detainments' Effect on Cases' Cerebral responses. The Emotional impacts of detention cases witness severe cerebral suffering when surgeries are delayed or cancelled. expansive waiting times are associated with physical and psychosomatic symptoms, as well as original responses similar to wrathfulness, rejection, and anxiety, according to exploration on surgical cancellations. Increased anxiety, perceptivity, and health anxiety are among the numerous adverse effects linked to lengthy surgical waiting times. Physiological Signs and Symptoms Detainments in surgery have a cerebral cost that shows up as quantifiable physiological differences. Anxiety measures are explosively identified with systolic blood pressure increases during the preoperative phase, according to studies, and cases with preoperative anxiety exhibit conspicuous blood pressure swings [**6**]. The Neurological Mechanisms Underpinning Stress and Aggression Responses: Pathways of the Central Nervous System. Numerous cerebral regions and neurotransmitter systems are implicated in the neurological

mechanisms that sustain preoperative aggression and stress responses. Investigations into functional neurological disorders illuminate the processes that govern aggression regulation, revealing that individuals with emotional dysregulation exhibit elevated levels of trait hostility and state aggression, as well as a pronounced attentional bias towards angry faces and difficulties in modulating aggression. [**7**]. long-term preoperative stress may vitiate the brain's natural inhibitory systems, which could lead to heightened emotional reactivity, including angry responses.On Surgical Results, Surgical issues are greatly impacted by preoperative solicitude and the internal anguish that goes with it. Considerations for Patient Safety-for individuals who are inherently at risk, the activation of the sympathetic nervous system during periods of preoperative stress is not only distressing but also represents a significant danger [**8**]. Visionary cerebral backing and stress-reduction strategies may be made possible by early discovery of cases who are susceptible to angry responses. Healthcare professionals should be apprehensive that delays in surgery might affect patient safety and results by causing complicated neurobiological stress responses in addition to logistical difficulties[**9**].Preoperative uneasiness remains a basic issue in the perioperative period [**10**]. This single-centre, cross-sectional cohort study was conducted at Hôpital de la Croix Rousse in Lyon to assess preoperative anxiety among adult patients passing through a shared surgical Transitional Waiting Area (TWA) before elective procedures. Utilizing approved tools—APAIS, Covi's uneasiness scale, and VAS-A—researchers measured uneasiness levelsand accumulated quiet recognitions.

Serious preoperative anxiety (SPA) was defined as an APAIS score of ≥11. Data were prospectively collected by trained healthcare professionals using computerized tablets, and statistical analyses were performed to investigate the associations between SPA and clinical or demographic variables. The study included 950 patients and adhered to French ethical standards, with oral consent considered sufficient [10].In a prospective observational study, existing anesthesiological preoperative information and previous experiences of 461 patients (255 women and 206 men) were documented. In addition, the emotional state of each patient was assessed before and after the premedication visit using a Visual Analogue Scale (VAS) and the Current Stress Test (KAB) [11]. A comprehensive literature search was conducted to identify studies examining the relationship between preoperative anxiety and postoperative adverse outcomes. The PubMed, Scopus, Web of Science, and Google Scholar databases were searched from inception to 2022 using the following keywords: *preoperative anxiety*, *postoperative adverse events*, *postoperative insomnia*, *postoperative sleep disturbance*, *postoperative pain*, *postoperative nausea and vomiting*, *perioperative neurocognitive disorders*, *postoperative cognitive dysfunction*, and *postoperative delirium* [12].

Preoperative Anxiety and Postoperative Insomnia

Insomnia is highly prevalent among perioperative patients and is closely associated with elevated levels of anxiety [13]. Several studies have demonstrated that patients with higher preoperative anxiety, measured using validated instruments such as the State-Trait Anxiety Inventory-State (STAI-S), Generalized Anxiety Disorder-7 (GAD-7), and Self-Rating Anxiety Scale (SAS), are significantly more likely to experience poor postoperative sleep quality. For example, data from 997 surgical patients in China revealed that individuals with high preoperative anxiety were nearly twice as likely to develop postoperative insomnia [14]. Similarly, retrospective and prospective cohort studies have reported that up to 31% of patients experienced insomnia in the weeks following surgery, with preoperative anxiety identified as a major predictive factor [15]. Postoperative sleep deprivation not only exacerbates pain and increases opioid consumption but also contributes to delirium, delayed recovery, and reduced long-term patient satisfaction. These findings emphasize the importance of identifying and managing preoperative anxiety to improve postoperative recovery and overall surgical outcomes [16]. The most common causes of preoperative anxiety include waiting for surgery, concerns about surgical outcomes, separation from family members, anticipation of postoperative pain, loss of independence, and fear of surgery or death (Figure 1). Excessive preoperative anxiety has also been recognized as a significant contributor to increased healthcare costs, placing an additional financial burden on healthcare systems [17].

DISCUSSION

The perioperative period is an exceptionally important time when individuals are more likely to experience mental distress. One of the biggest stressors during this time is having to wait for surgery. This review talks about how anger and anxiety affect preoperative patients in ways that are different from other patients, especially those who have to wait for surgery. Anger, while less extensively researched than anxiety, possesses significant neural and physiological consequences. Research shows that anger activates the sympathetic nervous system, which causes measurable changes in the body, like higher blood pressure, heart rate, and stress hormone release. These changes can make surgery outcomes worse [1,5,18]. The neurobiological basis involves complicated interactions between the central nervous system and endocrine pathways that may make postoperative problems worse, especially in patients who already have other health problems [5,6,18]. Anger and anxiety are examples of emotional problems that can happen before surgery, but can also continue and even get worse after surgery. Post-stroke anger (PSA) is just as common as post-stroke depression, but it is not as well-known. It shows up as impulsivity, aggression, and hostility [1,18]. Anger can be a result of cerebrovascular events, but it can also be a risk factor, showing how emotions and physical illness can affect each other in both directions. Anxiety is very common, affecting as many as 80% of people who have surgery [1,18].

Interpretation and integration with existing literature

Preoperative delays amplify uncertainty and loss of control—well-recognised triggers for anger and frustration in medical settings. Empirical work on surgical cancellations and delays documents substantial emotional distress among affected patients, including anger and perceived harm, suggesting that delays themselves act as important psychosocial stressors [19]. The perioperative literature linking preoperative anxiety with poorer postoperative outcomes (including sleep disturbance and greater analgesic requirements) is substantial, and recent prospective studies corroborate these associations. Although direct, large-scale studies isolating anger as the predictor are fewer, the overlap and mechanistic parallels between anxiety and anger (both drive sympathetic and inflammatory activation) support the hypothesis that anger can similarly predict adverse outcomes such as postoperative insomnia, increased pain, and possibly cognitive complications [20]. Uneasiness in the setting of "catastrophic pain", i.e., a solid negative response to genuine or anticipated torment, is too connected to extreme postoperative torment [21]. The higher the degree of preoperative uneasiness, the higher the necessity for postoperative absense of pain [22]. Anesthesiologists and specialists ought to hence pay more consideration to patients' preoperative antagonistic feelings to permit a opportune alteration of perioperative pharmaceutical to accomplish individualized administration [23]. Individuals showing less capacity to direct the expression of their outrage discharged more cortisol in reaction to the stretch related with the rankling strategy. More noteworthy cortisol generation was, in turn, related with deferred mending [24]. They found that higher levels of shock control were related to a reduced repeat and concentration of assumptions of shock as well as less extraordinary anger-related comes about. Too, individuals with lower control over the expression of their shock appear up to utilize less capable adjusting methods, driving to more mental inconvenience and poorer quality of life than those with higher shock control [25]. The cortisol reaction to this gentle stretch was more noteworthy among people showing less control over the expression of their outrage than among members who detailed higher levels of outrage control.

Clinical implications

Communication and expectation management: Transparent, timely information about reasons for delay and revised timelines can reduce perceived loss of control and mitigate anger escalation. Evidence from cancellation studies emphasizes the patient harm (emotional and practical) caused by poor communication [26]. Targeted interventions: Brief CBT, anger management strategies, relaxation training, and structured preoperative counseling (including digital or VR tools for anxiety/anger reduction) should be trialed as components of "emotional prehabilitation" during waiting periods. Interventions that reduce sympathetic/HPA activation may have downstream physiological benefits [27]. Medical risk optimization: Because anger potentiates cardiovascular reactivity (BP/HR surges) and inflammatory responses, optimizing blood pressure, glycemic control, and sleep may reduce downstream adverse

events in high-anger patients. Monitoring perioperative physiology (e.g., BP variability, HRV) in flagged patients could guide perioperative management [27].

Limitations of current evidence

Direct evidence gap: Few prospective studies specifically quantify preoperative anger (distinct from anxiety) and correlate it with objective postoperative endpoints (wound infection, length of stay, analgesic consumption, delirium). Measurement heterogeneity: Existing studies use diverse instruments and conflate constructs (irritability, hostility, general distress), complicating meta-analytic synthesis [28]. Temporal and dose–response unknowns: The effect of short (hours) versus long (weeks–months) delays on anger trajectories and biological markers is not well defined. Confounding: Many studies do not fully adjust for comorbid psychiatric illness, social determinants, or perioperative analgesic/anesthetic strategies that modulate outcomes [29]. As one of the most common clinical issues in perioperative patients, preoperative uneasiness is closely related to the occurrence of postoperative adverse outcomes. Various clinical considers have certified that preoperative anxiolytic medications can effectively diminish the chance of postoperative unfavorable occasions. Hence, paying more attention to patients' preoperative uneasiness and taking more successful activities will help guarantee the safety of patients and improve their satisfaction. All things considered, due to their complicated relationship, thinking about the components of preoperative uneasiness influencing postoperative unfavorable occasions is generally uncommon. Hence, investigating the correct components and distinguishing modern restorative targets ought to be a need for future work [30].

CONCLUSION

The perioperative period represents a unique intersection of physiological vulnerability and psychological strain, where emotional states such as anger and anxiety exert profound influences on patient experiences, safety, and outcomes. Delays in surgery, even though they are frequently inescapable due to calculated or restorative reasons, escalate this vulnerability by opening up instability, disintegrating patients' sense of control, and increasing the chance of negative emotional reactions. Whereas preoperative uneasiness has long been recognized as a major determinant of antagonistic postoperative outcomes—including sleep deprivation, pain worsening, increased opioid requirements, and impaired recovery—anger has verifiably received less attention despite its similarly noteworthy neurobiological effects. The proof checked on underscores that outrage is not a temporal or simply behavioral reaction but a complex psychophysiological wonder driven by thoughtful apprehensive framework activation, increased push hormone discharge, and dysregulated neural pathways administering hostility and passionate control. These changes show not only as lifted blood weight and heart rate but also as fiery and endocrine cascades that may impede wound healing, compound cardiovascular risk, and decrease surgical healing potential. In addition, outrage offers unthinking pathways with anxiety—such as thoughtful actuation and hypothalamic–pituitary–adrenal (HPA) hub dysregulation—suggesting that it may contribute to a comparative range of unfavorable results, including postoperative torment, sleep disturbances, and neurocognitive impairment. Importantly, preoperative shock should not to be conceptualized only as a open state but additionally as a prescient marker of postoperative complications, particularly in patients with pre-existing comorbidities like hypertension, diabetes, or cerebrovascular ailment. The composing on post-stroke shock diagrams the bidirectional relationship between feeling and physiology, where shock both comes around from and contributes to cerebrovascular pathology.

In surgical settings, outrage activated by delays or destitute communication may not only cause enthusiastic trouble but also potentiate pathophysiological forms with unmistakable clinical results. From a clinical point of view, this audit highlights a few basic suggestions. To begin with, clear communication and crave organization are crucial in directing shock in the midst of surgical delays. Patients are less likely to experience uncontrolled energetic increasing when delays are clarified immediately, empathetically, and with clear timelines Moment, organized mental interventions—including cognitive behavioral treatment (CBT), unwinding preparation, outrage administration methodologies, and imaginative tools such as computerized counseling or virtual reality—offer promising roads for "emotional prehabilitation" that may decrease thought overactivation and improve perioperative strength. Third,

helpful optimization must be facilitated with mental care. Checking perioperative blood weight irregularity, heart rate changes, and extend markers in high-risk patients can offer coordinate mediations and minimize unfavorable effects. At the same time, current advance perseveres from extraordinary obstacles. The deficiency of arranged thinks about, especially measuring shock, heterogeneity in estimation devices, and a require of control for confusing psychosocial or pharmacological components, compels our capacity to draw conclusive conclusions. The worldly measurement of anger—whether brief scenes in reaction to intense delays or drawn-out passionate trouble over weeks of waiting—remains underexplored, as does its dose–response relationship with surgical results. Tending to these proven holes is vital for progressing perioperative care. Ultimately, the integration of mental evaluation into scheduled surgical pathways is no longer discretionary but fundamental. Fair as preoperative optimization presently routinely addresses nourishment, comorbid illness, and functional capacity, so too must it efficiently address emotional states such as outrage and uneasiness Recognizing outrage as a genuine and impactful component of preoperative push will not only provide quiet fulfillment but also improve security, diminish complications, and advance all-encompassing recuperation. Future inquiries ought to point to clarify the robotic underpinnings, refine estimation instruments, and test focused intercessions that bridge the partition between mental well-being and surgical results. In conclusion, surgical delays speak to more than calculated challenges; they are strong psychosocial stressors able to incite outrage and uneasiness with quantifiable physiological results. By recognizing, surveying, and attending to these passionate reactions, healthcare frameworks can move toward a more patient-centered, flexible, and secure approach to perioperative care.

ABSTRACT

This paper focuses on the multi-objective optimization problem of traffic congestion at urban junctions due to high density and varying flow conditions, which is one of the major issues related to a smart city. An innovative traffic signal control system using the multi-objective optimization theory and adaptive artificial fish swarm algorithm (AAFSA) [18] is suggested in this paper. Performance criteria like average delay time, average number of stops, and travel time are used in the development of this model. An expression for the state of traffic flow is developed based on the parameters related to the traffic flow. Based on these parameters, an optimization model is developed using the adaptive artificial fish swarm algorithm. Through simulation studies, it is observed that there is a marked improvement in traffic flow.

Keywords: Smart City, Traffic Signal Optimization, Multi-objective Optimization, Artificial Fish Swarm Algorithm, Swarm Intelligence, Traffic Flow Modeling

INTRODUCTION

Urbanization, population increase, and the rise in vehicular traffic have contributed to a significant congestion problem in cities, especially in emerging economies like India. Intersections are among the busiest sections of roads and serve as important nodes where many traffic flows meet. Poor coordination of traffic signals at intersections can cause delays, fuel inefficiencies, pollution, and network inefficiencies. Traffic signal control (TSC) forms an integral part of efforts by smart cities to minimize congestion and improve transportation, as seen in modern literature [1].Traditional TSC systems, including fixed time and actuated systems, are poorly equipped to handle dynamic adjustments to fluctuating traffic levels. They use static traffic management systems that have trouble adapting to

current conditions, making them less efficient when dealing with different traffic situations. The emergence of ITS has led to a shift in traffic signal control to more adaptive and data-driven models. In particular, AI-based solutions, such as machine learning and reinforcement learning, show potential for improving traffic signal operation using real-time data [2].

Deep reinforcement learning (DRL) has driven improvements in the development of adaptive traffic signal control systems. Distributed learning schemes, such as federated reinforcement learning, allow coordination of multiple intersections without compromising scalability in large-scale urban traffic networks. Nevertheless, DRL algorithms should be improved to enhance their ability to adapt to complex and highly dynamic traffic environments [3][4]. Despite these benefits, the practical implementation of reinforcement learning for TSC remains challenging due to several constraints, including extensive training needs, large datasets and computational resources, and well-designed reward schemes.At the same time, swarm intelligence and evolutionary computation techniques have shown great potential for solving intricate traffic signal optimization problems. For instance, Particle Swarm Optimization (PSO), Genetic Algorithms (GA), Ant Colony Optimization (ACO), and Artificial Fish Swarm Algorithm (AFSA) represent some of the most widely used algorithms because of their capability in dealing with nonlinear optimization problems, along with effective global search ability and adaptability. One of the latest research works suggests that swarm intelligence-based systems outperform conventional traffic management methods by achieving a delay reduction of around 25-30% [1][5][6][7].

The efficiency of swarm intelligence algorithms in exploring and exploiting large search spaces makes them ideal for traffic light optimization, where they can mimic their actions by studying natural occurrences. The AFSA [18] is one such algorithm and has become increasingly popular owing to its simplicity, quick convergence, and its ability to perform exceptionally well without falling into local minima traps. The AFSA works on principles similar to those adopted by fish in their search for food, grouping, and schooling behavior, thus ensuring that they converge towards their optimum values iteratively. Recent research has shown that AFSA outperforms conventional optimization techniques in dynamic traffic environments [5][7].A crucial step towards achieving efficient traffic signal control under the modern traffic management regime lies in realizing that there are many conflicting objectives that need to be considered during optimization. The problem with conventional approaches is that they are focused on optimizing one objective at a time (e.g., delay, queuing length), failing to consider all the complexities associated with traffic flows. Multi-objective optimization takes into account more objectives simultaneously, for instance, average delay, stops, travel time, fuel economy, and emissions.

The combination of the Internet of Things, intelligent sensing technologies, and data analytics has made possible the creation of intelligent traffic control systems. In the context of smart cities, this technology allows real-time control of traffic flows as well as the adaptation of signal times. Taking into account the complex nature of traffic flow dynamics that can be regarded as non-linear, stochastic and variable, robust algorithms should be used to overcome uncertainties. In order to overcome these issues, a multi-objective optimization algorithm for the traffic signal control based on AAFSA was proposed. The AAFSA algorithm can be considered an extension of the AFSA with improved searching speed and solution accuracy due to adaptive parameter selection. Multiple objectives such as average delay, stop number, and travel time are considered. The following is a brief overview of the key objectives of this paper:

- derivation of traffic flow state equation for smart cities' intersection;
- creation of a multi-objective optimization problem to optimize traffic signals control;
- application of the adaptive optimization approach based on ACS/AFSA algorithm; and
- assessment of the proposed solution with extensive simulation experiments.

The outline of the rest of the paper proceeds as follows: Traffic Flow State Equation in Section 2, Optimization Model in Section 3, Adaptive Approach Based on AFSA in Section 4, and the experimental analysis will be discussed afterward.

Establish the Equation of State of Traffic Flow

A traffic flow model at signalized intersections is a key tool for designing an efficient adaptive traffic signal control system. The traffic flow in smart cities is very dynamic and dependent on several factors including the number of vehicles arriving, signal timing, Road geometry, and driver behavior. To model these dynamics, the equation of state of traffic flow is created, a mathematical model that is considered as the relationship between the flow, density, speed and signal parameters.

Fundamental Traffic Flow Relationships

Traffic flow theory mainly depends on three key parameters that include traffic flow q, traffic density k, and average speed v. The simplest equation that exists between these parameters is: $q = k \cdot v$…(1)
Here, q indicates traffic flow (vehicles per hour),k indicates traffic density (vehicles per kilometer) and v represents average vehicle speed (km/h).Equations such as (1) serve as the foundation for traffic flow studies and analysis in urban traffic systems [9][11].

Traffic Flow Dynamics at Signalized Intersections

In signalized junctions, traffic flow gets affected by phase interruptions due to signals causing queues. Traffic flows on green lights get limited by the saturation flow rate "s" which is the highest traffic flow rate possible under ideal conditions at the junction.The effective flow during a signal cycle can be expressed as:

$$q_i = s_i \cdot \frac{g_i}{C} \quad \ldots (2)$$

Where, q_i = actual flow rate for phase i,s_i = saturation flow rate for phase i,g_i= effective green time for phase i,C = total signal cycle time. Equation (2)the relationship between the duration of the green light divided by the cycle time, which is the crucial parameter to determine the traffic volume efficiency in the signalization design [12].

Queue Length and Delay Modeling

The length of the queue formed at the intersection is a dynamic factor depending on the arrival and departure rate. The equation of queue propagation can be expressed as:

$$Q_i(t+1) = Q_i(t) + A_i(t) - D_i(t) \ldots (3)$$

Where, $Q_i(t)$represents the queue length at time t,$A_i(t)$represents arrival rate and $D_i(t)$is the departure rate.

$$d = \frac{C\left(1-\frac{g}{C}\right)^2}{2(1-x)} + \frac{x^2}{2q(1-x)} \ldots (4)$$

The user delay which is one of the performance measures used is estimated by using Webster's delay model(eq. 4) using x to show the level of saturation. Where x is the degree of saturation. It helps quantify the impact of signal timing on user delay [13][15].

Signal Cycle Time Constraint Equation

The total cycle time can be considered as the total green time for all the phases including the total lost time due to startup and clearance times. Cycle time relation is expressed as:

$$C = \sum_{i=1}^{n} g_i + L \ldots (5)$$

Where, $C$is total cycle time,$g_i$is time for green light for the ith phase,L is the total lost time per cycle ,$n$is total number of phases. This ensures that the signal timings plans are feasible and reliable [16].

Degree of Saturation and Stability Condition

The degree of saturation becomes the key parameter which decides the traffic system to be in either a steady or saturated state. Degree of saturation is expressed as:

$$x = \frac{q}{s \cdot (g/C)} \ldots (6)$$

In equation (6) if $x < 1$ then it refers to stable flow condition, and $x \geq 1$ refers to oversaturated condition (congestion).Maintaining $x < 1$ is required to avoid excessive queue buildup and system instability and unreliability [17].

Integrated Traffic Flow State Equation

The combination of all relationships discussed above results in a dynamic multi-variable system which describes the traffic flow state at an intersection under control by a traffic light.

$$F = f(q_i, k_i, v_i, g_i, C, s_i, Q_i) \ldots (7)$$

Equation (7) thus obtained summarizes interdependencies between various traffic flow and traffic signals variables and forms the basis for optimization models of adaptive control of traffic lights within smart urban environment.

Building an Optimization Model for Traffic Signal Control at Intersections in Smart Cities

Optimal traffic control of a traffic light at an urban intersection requires an efficient optimization method that would take into account the dynamics and uncertainty of traffic processes. As part of the problem of smart cities, this task is inherently multi-objective in nature because several performance measures need to be optimized simultaneously. In this section, the multi-objective optimization model of traffic control based on traffic flow equations obtained above will be formulated.

Decision parameters

Decision parameters of the traffic signal optimization problem include:
g_i: Effective green time for phase i, C: Cycle length of signal, ϕ_i: Phase sequencing and phasing (in case of coordinated operation). All these mentioned parameters affect traffic efficiency and effectiveness.

Objective Functions

In order to reflect the behaviour of realistic traffic environment, multi-objective optimization approach is considered. Below are the most important goals of the optimization model:
(i) Minimization of Average Delay
Average delay is one of the most important objectives that reflects the state of the traffic system. It may be described as:

$$\min f_1 = D_{avg} = \frac{1}{N} \sum_{i=1}^{n} \sum_{t=1}^{T} d_i(t) \quad \ldots (8)$$

where, D_{avg} refers to the average delay, N indicates the total number of vehicles, $d_i(t)$indicates the delay incurred by the vehicles in phase $i$at time t.
(ii) Minimization of Number of Stops
Repeated stopping results in greater fuel usage and emission rates. The objective function can be expressed as:

$$\min f_2 = S_{avg} = \frac{1}{N} \sum_{i=1}^{n} S_i \ldots (9)$$

where, $S_i$refers to the number of stops made during phase i

(iii) Minimization of Total Travel Time

$$\min f_3 = T_{travel} = \sum_{i=1}^{n} \sum_{j=1}^{N_i} t_{ij} \ldots(10)$$

where, t_{ij} is the travel time of vehicle j during phase i.
(iv) Combined Multi-objective Function
Given that the problem involves multiple objectives, the weighted aggregation method is adopted:

$$F = w_1 D_{avg} + w_2 S_{avg} + w_3 T_{travel} \ldots(11)$$

Where, w_1, w_2, w_3indicates the weight assigned to each objective.

Constraints of the Optimization Model
The optimization model is subject to several practical constraints:
(i) Cycle Time Constraint

$$C = \sum_{i=1}^{n} g_i + L \ldots(12)$$

where $L$is the total lost time.
(ii) Green Time Bounds

$$g_i^{min} \leq g_i \leq g_i^{max} \ldots(13)$$

Equation (13) ensures safety and operational feasibility.
(iii) Degree of Saturation Constraint

$$x_i = \frac{q_i}{s_i(g_i/C)} \leq 1 \ldots(14)$$

This constraint helps to stabilize the traffic flow and avoids oversaturation.
(iv) Queue Stability Constraint

$$Q_i(t+1) \leq Q_i^{max} \ldots(15)$$

This prevents massive queue buildup at junctions.
(v) Non-negativity Constraint

$$g_i, C \geq 0$$

Optimization Model Solution Based on Adaptive Artificial Fish Swarm Algorithm

The multi-objective optimization problem for traffic signal control that is formulated above is solved using AAFSA. AAFSA can be considered as an advanced version of AFSA, which was created to increase the speed of convergence, prevent the algorithm from falling into local optimums and adapt to traffic changes.

Overview of AFSA
AFSA is an algorithm that falls under the category of a population-based optimization algorithm. The AFSA is inspired by behaviours of fish as a group. This means that each artificial fish in the algorithm represents a possible solution in the problem space, whereas the algorithm is based on behaviours such as prey, swarm, follow, and random behaviours.

Artificial fish's position can be defined as follows:

$X_i = (g_1, g_2, \ldots, g_n, C) \ldots (16)$

where X_i is an actual signal timing plan, which includes green time and cycle length.

Fitness Function Design

Fitness for each individual artificial fish (solution) is calculated based on the previously proposed multi-objective fitness function. The integrated fitness function is:

$Fitness(X_i) = F = w_1 D_{avg} + w_2 S_{avg} + w_3 T_{travel} \ldots (17)$

The goal here is to find the best possible signal-timing settings that will give us the minimum fitness value.

RESULTS AND DISCUSSION

In this section, we shall be presenting the results obtained from our experiments and analysing the behaviour of the suggested AAFSA in optimizing the traffic signals in smart cities.

Results of Traffic Signal Optimization

Our optimization scheme using the AAFSA method was tested under different traffic conditions ranging from low, moderate, to heavy traffic load situations. We have compared our approach with other approaches like fixed-time signal control (FTSC), Webster, PSO, and AFSA.

Improvement in Average Delay

The results of simulations show an evident decrease in average vehicle delay using AAFSA in comparison with other methods:(1) Reduction by 20-35% compared to FTSC (2) Reduction by 10-18% compared to PSO (3) Reduction by 8-12% compared to standard AFSA.

These benefits can mainly be explained by the fact of the adaptive green time allocation as well as more efficient searching within the problem domain.

Comparative Analysis

A comparative evaluation of different methods is summarized below: The results clearly indicate that AAFSA

DISCUSSION

These benefits can mainly be explained by the fact of the adaptive green time allocation as well as more efficient searching within the problem domain. As is evident from the analysis above (Table:1), the use of AAFSA allows achieving superior results as compared to alternative approaches. The experimental results confirm the effectiveness of the developed optimization model based on AAFSA in the context of traffic signal control. The considerable decreases in delay, queue length, and stops indicate the advantage of a multi-objective approach over single-objective solutions. One of the main advantages of the suggested model is the ability to take into account multiple objectives at once. In contrast to existing approaches where only delay is minimized, our approach considers delays, stops, and travel times simultaneously, providing thus more relevant results. The adaptive nature of the AAFSA algorithm plays a key role in terms of increasing performance. Specifically, it allows changing visual distance and step size so as to conduct global search in the beginning and refine the solutions found at subsequent steps. Additionally, it allows using chaotic search in order to avoid trapping into local optima. Another advantage of our model is that it proves to be stable regardless of traffic density. It works well not only at low and medium traffic but also at high traffic

densities which makes the model promising in terms of real-life application. Nonetheless, there are a few drawbacks in the use of our model. First, the increase in the scale of traffic networks leads to higher computational complexity. Second, the model requires correct traffic data to work, which is not always available in practice. In spite of the identified problems, the AAFSA model demonstrates considerable promise of applicability in the field of intelligent transportation systems. Further developments include using machine learning and IoT technologies to improve the efficiency of the algorithm.

CONCLUSION

This paper introduces a novel multi-objective optimization technique applied to traffic light control at intersections in smart cities via AAFSA. The proposed model is able to efficiently minimize important traffic parameters such as average delay, length of queues, and number of stops. Moreover, owing to its adaptability property, the algorithm shows better convergence speed and a tendency to avoid falling into local optimal solutions compared to existing techniques. As proven by experimental investigations done by the author, the new technique surpasses traditional methods and other metaheuristic techniques used in traffic signalling. Although the model demonstrates outstanding performance, further studies need to be undertaken on the issues of scalability and real-time information inclusion.

ABSTRACT

Pharmaceutical product lifecycle management (PLM) has become increasingly complex due to globalization, fragmented regulatory frameworks, and frequent post-approval changes (PACs). Traditional regulatory pathways often impose disproportionate burdens, leading to duplicative submissions, inconsistent categorization, and extended approval timelines. To address these inefficiencies, this study introduces the Predictive Risk-Based Regulatory Lifecycle Model (PR-RLM), a novel governance framework designed to embed quantitative risk scoring, predictive analytics, and harmonized reliance mechanisms into lifecycle management. At the core of PR-RLM is the Post-Approval Regulatory Risk Burden Index (PRRBI), a composite metric that integrates regulatory complexity, quality impact, and approval timeline burden into a transparent, measurable score. By converting qualitative judgments into quantitative outputs, PRRBI enables proactive forecasting of regulatory burden and facilitates strategic decision-making for both regulators and industry stakeholders. Structured case-based validation was conducted across three representative scenarios excipient grade changes, manufacturing site transfers, and analytical method updates. Results demonstrated that PR-RLM consistently reclassified changes into lower risk tiers compared to traditional frameworks, reducing regulatory burden by 30–50%, shortening approval timelines by several months, and eliminating duplication across jurisdictions.

Key words: Pharmaceutical lifecycle management; Regulatory science; Post approval changes (PACs); ICH Q12; Risk based regulation; Predictive analytics; PRRBI; Harmonization.

INTRODUCTION

Pharmaceutical Lifecycle Management

Pharmaceutical Lifecycle Management (PLM) refers to the comprehensive and systematic oversight of a medicinal product from its initial discovery through development, commercialization, and eventual discontinuation. The lifecycle begins with drug discovery and preclinical research, progresses through clinical development and regulatory approval, and continues into large-scale commercial manufacturing and post-marketing surveillance. Unlike traditional models that emphasized market authorization as the endpoint of regulatory scrutiny, modern lifecycle management recognizes that regulatory engagement intensifies after approval. Although the granting of marketing authorization represents a critical milestone, the majority of regulatory activity occurs during the post-approval phase. [5]. Figure 1: Pharmaceutical Product Lifecycle Management Model: Continuous Improvement Approach This figure illustrates the comprehensive lifecycle of a pharmaceutical product, beginning from

Post-Approval Change (PAC) Governance Challenges

Despite the adoption of risk-based quality frameworks and lifecycle-oriented regulatory philosophies, governance of post-approval changes remains structurally fragmented. One of the primary challenges is jurisdictional diversity. Regulatory authorities across different regions apply distinct change classification systems, commonly categorizing modifications as major, moderate, or minor. However, the criteria underlying these classifications often vary, leading to inconsistent regulatory outcomes. A single manufacturing change may be considered a major variation in one jurisdiction, a moderate variation in another, and merely a notification in a third. Such inconsistency complicates global regulatory strategy and undermines predictability. Companies are frequently required to prepare separate submission packages tailored to each authority's specific expectations, even when the scientific justification remains identical. [6–8].

Risk-Based Regulation in Pharmaceutical Governance

Regulatory science has progressively embraced risk-based methodologies to enhance efficiency and focus oversight on changes that meaningfully impact product quality and patient safety. Risk-based principles aim to allocate regulatory scrutiny proportionally, concentrating resources on high-impact modifications while reducing unnecessary review of low-risk changes. This approach encourages innovation and continuous improvement while preserving safety standards. Existing regulatory frameworks outline systematic approaches for risk identification and risk assessment. They describe tools such as quality risk management processes and provide general pathways for categorizing post-approval changes. [12–14].

Administrative Risk Amplification

A critical and often under-recognized issue in post-approval governance is the inflation of regulatory burden arising from structural inefficiencies rather than genuine product risk. Certain types of changes, such as manufacturing site transfers, are frequently classified as high-risk events even when equivalent Good Manufacturing Practice (GMP) systems are demonstrated. Similarly, analytical method updates that do not alter product specifications may receive divergent classifications across regions [18–20].

Rationale for Developing the Predictive Risk-Based Regulatory Lifecycle Model (PR-RLM)

To address the structural inefficiencies identified in contemporary PAC governance, this thesis proposes the development of the Predictive Risk-Based Regulatory Lifecycle Model (PR-RLM). The model seeks to move beyond qualitative guidance toward measurable, data-driven regulatory decision support. The PR-RLM is designed to quantify regulatory burden, align oversight intensity with scientific impact, reduce duplication of regulatory effort, enhance global predictability, and support harmonized decision-making across jurisdictions. Rather than replacing existing frameworks, it builds upon established risk management principles and integrates them into a structured scoring architecture [30].

Study Rationale and Objectives

This study aims to conduct a comparative regulatory gap analysis of pharmaceutical lifecycle frameworks to identify inefficiencies in post-approval change governance. It further proposes the conceptualization of a Predictive Risk-Based Regulatory Lifecycle Model (PR-RLM) based on ICH Q9 Quality Risk Management and ICH Q12 Pharmaceutical Product Lifecycle Management, and the development of a quantitative regulatory risk-scoring mechanism to forecast lifecycle regulatory burden and approval impact. [30].

METHODOLOGY

Research Design

This study adopts a mixed method research design integrating comparative regulatory analysis, predictive model construction, quantitative scoring development, and case based simulation validation. Mixed methods are suitable for regulatory science research where normative guideline interpretation (qualitative) and predictive metric generation (quantitative) are combined to build a working governance model. The initial phases focus on regulatory framework comparison and gap identification, which inform model design. Subsequent phases operationalize regulatory risk scoring and empirically validate the model through simulation of real post approval change scenarios.[1–3].

Comparative Regulatory Systems Analysis

The comparative regulatory analysis examines regulatory frameworks governing post approval change control and lifecycle management. Primary sources include harmonized guidelines and technical guidance from major regulatory authorities notably the International Council for Harmonization guideline ICH Q12 and its implementation documents published by the U.S. Food and Drug Administration (FDA) and the European Medicines Agency (EMA). This analysis maps the structures and expectations of lifecycle governance in each regulatory system, including: reporting categories for post approval changes, principles of risk and science-based regulation, and the presence/absence of tools such as Established Conditions (ECs) and Post Approval Change Management Protocols (PACMPs).

Comparative Regulatory Findings

A systematic comparison of post approval lifecycle governance frameworks reveals significant structural and procedural differences among major regulatory authorities. The International Council for Harmonization (ICH) Q12 guideline provides a harmonized scaffold intended to facilitate risk-based management of post approval chemistry, manufacturing, and control (CMC) changes across jurisdictions. According to the EMA's Q12 scientific guideline, this framework "addresses the commercial phase of the product lifecycle … to facilitate the management of post approval CMC changes in a predictable and efficient manner" and complements existing ICH quality system principles [6,14].

Table 1: Comparative Analysis of Post-Approval Change Management Frameworks: FDA vs EMA This table presents a comparative evaluation of post-approval change management systems followed by the U.S. FDA and the European Medicines Agency (EMA). It highlights differences in change categorization, risk-based regulatory tools, documentation requirements, and stability-related lifecycle submissions.

Structural Inefficiencies in Post Approval Governance

Current lifecycle governance frameworks exhibit structural inefficiencies that can increase compliance burden and reduce regulatory predictability. A particularly notable inefficiency arises from the lack of uniform adoption of predictive lifecycle tools across jurisdictions. While the ICH Q12 guideline proposes risk-based categories and protocols to streamline post approval change management, their implementation is uneven, which detracts from the intended benefits of harmonised regulation. [16–18].

Limitations of the Model: Despite its structured design, the PRRLM has certain limitations.
First, weight assignments are based on expert-informed regulatory hierarchy rather than empirical regression calibration. Absence of large-scale submission outcome datasets limits statistical optimization. Second, jurisdiction-specific enforcement variability may influence real-world regulatory outcomes. Periodic recalibration may be necessary to maintain predictive accuracy. Third, the model uses a linear composite structure, which may not fully capture nonlinear interactions between certain regulatory determinants.

RESULTS AND DISCUSSIONS

The results of this study present the measurable outcomes of the comparative regulatory gap analysis conducted across major pharmaceutical jurisdictions. The findings summarize how differences in post-approval change (PAC) governance frameworks influence approval timelines, risk categorization consistency, regulatory burden, and global lifecycle efficiency. Rather than focusing on individual regulatory authorities in isolation, the results are organized around key regulatory performance domains to enable a structured understanding of systemic inefficiencies across frameworks. To illustrate these findings, the results are categorized into major analytical domains, including PAC classification systems, approval timeline variability, risk categorization alignment, duplication of submissions, and reliance mechanisms. This domain-based organization allows identification of recurring structural gaps that persist despite harmonization efforts under international lifecycle management principles. Aggregated comparative data are supported by tabulated metrics and graphical representations demonstrating cross-regional timeline disparities and regulatory burden variation under traditional frameworks. Pharmaceutical lifecycle frameworks are designed to safeguard drug quality, safety, and efficacy throughout development, approval, and post-market phases. A critical component is post-approval change (PAC) governance, which regulates modifications to manufacturing processes, formulations, packaging, or analytical methods after a product has been approved. Table2. Comparative Overview of Post-Approval Change (PAC) Frameworks Across Major Regulatory Regions This table provides a comparative analysis of post-approval change (PAC) classification systems across key regulatory authorities, including the US, EU, Canada, Australia, and selected LATAM/APAC regions.

Structural Inefficiencies
Global post-approval change (PAC) management faces several regulatory inefficiencies. Regulatory fragmentation is evident as European Union member states often interpret variation guidelines differently, while many LATAM and APAC countries require duplicative submissions for the same change. Extended timelines further complicate lifecycle management; major changes such as FDA Prior Approval Supplements and EMA Type II variations can take more than 6–12 months for approval, delaying innovation and manufacturing improvements. Risk categorization also varies across jurisdictions, with regulators such as Australia allowing streamlined pathways for low-risk changes while others mandate full reviews. Additionally, limited digitalization and poor transparency in submission tracking, particularly in LATAM/APAC regions, continue to slow regulatory approvals. Table3. Comparative Timelines for Major PAC Approvals Comparison of approval timelines for major post-approval changes across regulatory agencies, highlighting variations in review duration and regulatory process efficiency.

Development of an Integrated Predictive Risk-Based Regulatory Lifecycle Model (PR-RLM)
Conceptual Framework Design: The Predictive Risk-Based Regulatory Lifecycle Model (PRRLM) was developed to address the fragmented and variable nature of post-approval change management across global pharmaceutical regulatory systems. The model is grounded in the principles articulated in ICH Q12: Technical and Regulatory Considerations for Pharmaceutical Product Lifecycle Management, which seeks to facilitate post-approval Chemistry, Manufacturing and Controls (CMC) changes in a predictable and efficient manner while strengthening quality assurance and supply continuity. The conceptual framework of PRRLM integrates multiple streams of regulatory intelligence, including risk attributes of changes, jurisdictional reporting requirements, Established Conditions, and historical regulatory enforcement trends, into a unified predictive structure. The model's primary output, the Predictive Regulatory Risk Burden Index (PRRBI), quantitatively estimates the anticipated regulatory

burden associated with a given change scenario. In essence, PRRLM converts qualitative regulatory expectations into a structured quantitative forecasting tool that supports strategic decision-making in regulatory lifecycle planning. The framework incorporates: The proposed framework integrates key components to support predictive and risk-based lifecycle management. It incorporates input elements such as change descriptors and product characteristics, which are evaluated through a structured risk stratification logic to determine regulatory impact. Regulatory control mechanisms, including Established Conditions and reporting categories described in ICH Q12 Pharmaceutical Product Lifecycle Management, are embedded within the system. The framework generates predictive outputs such as PRRBI scores and recommended submission pathways, enabling proactive, risk-informed regulatory decision-making aligned with principles of the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use. Figure 2: Framework for the Development and Implementation of the Predictive Risk-Based Regulatory Lifecycle Model (PR-RLM) This figure illustrates the structured development process of the Predictive Risk-Based Regulatory Lifecycle Model (PR-RLM), beginning with the establishment of a regulatory knowledge base and progressing through risk variable identification and model formulation.

Integration of Risk Stratification Principles

Risk stratification forms the core of the PR-RLM framework, aligning with risk-based regulatory approaches promoted in ICH Q12 Pharmaceutical Product Lifecycle Management and earlier quality guidelines of the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use. Within PR-RLM, each post-approval change is systematically assessed using key risk determinants, including potential impact on Critical Quality Attributes (CQAs), relevance to Established Conditions (ECs), the technical complexity of the change (such as process or analytical variations), and the number of regulatory jurisdictions affected. [9,13].

Regulatory Burden Index (RBI)

A higher RBI indicates a higher predicted regulatory burden, often associated with greater documentation requirements and prior approval expectations, whereas a lower RBI may indicate a change that could be managed principally within an internal Pharmaceutical Quality System (PQS).

Incorporation of Established Conditions

A cornerstone of ICH Q12 is the concept of Established Conditions (ECs), which formally define the elements of a regulatory dossier associated with product quality, process, and control. Changes to ECs normally require regulatory reporting or approval; changes outside of ECs may be managed within a sponsor's Quality System with reduced regulatory burden.

Harmonized Global Submission Planning

Global regulatory divergence remains a challenge in lifecycle management despite harmonization efforts under ICH Q12 Pharmaceutical Product Lifecycle Management. The PR-RLM framework addresses this by integrating regulatory rule sets from multiple jurisdictions and simulating predicted regulatory outcomes. This enables comparison of reporting requirements, alignment of global submissions, and anticipation of asynchronous regulatory expectations. The model architecture includes an input module, risk engine, predictive logic, and output interface, collectively generating recommendations on regulatory burden and optimal submission strategies for proactive lifecycle planning. Figure 3: Conceptual Framework of the Predictive Risk-Based Regulatory Lifecycle Model. This figure presents the conceptual cycle of the Predictive Risk-Based Regulatory Lifecycle Model, illustrating the integration of risk stratification, established conditions, and proactive change strategies within pharmaceutical lifecycle management.

Comparative Regulatory Assessment of Excipient Grade Change: Traditional Approach vs PR-RLM Model

In the traditional regulatory approach, an excipient grade change is treated as a major variation, requiring a U.S. Food and Drug Administration Prior Approval Supplement (~10 months) and European Medicines Agency Type II variation (~8 months), while LATAM/APAC regions require duplicative submissions extending timelines up to 14 months. Under the PR-RLM approach aligned with ICH Q9 Quality Risk Management principles, predictive risk

assessment classifies the change as moderate risk, enabling harmonized global review pathways and reducing approval timelines to approximately six months.

Construction of the Predictive Regulatory Risk Burden Index (PRRBI)

The Predictive Regulatory Risk Burden Index (PRRBI) quantifies regulatory burden by identifying key risk variables influencing post-approval change evaluation. These include change criticality affecting CQAs and Established Conditions, jurisdictional complexity across agencies such as the U.S. Food and Drug Administration, European Medicines Agency, and Central Drugs Standard Control Organization, potential quality or safety impact, historical regulatory outcomes, and documentation requirements. Weight assignments are determined using risk management principles from ICH Q9 Quality Risk Management, regulatory priorities, enforcement trends, and expert consultation. Toward a Harmonized Regulatory Framework Table 4: Example weighting schema for Predictive Regulatory Risk Burden Index This schema demonstrates that variables reflecting core regulatory impact (such as Established Conditions) are given greater weight due to their strong influence on review outcomes and submission complexity. Figure 4: Post-Approval Regulatory Risk Burden Index (PRRBI) Framework for Risk-Based Decision Making. This figure illustrates the structured framework of the Post-Approval Regulatory Risk Burden Index (PRRBI), which quantifies regulatory risk associated with post-approval changes. It demonstrates the systematic process of identifying risk variables, assigning weights, calculating composite scores, and classifying changes into defined risk tiers.

CONCLUSION

The study demonstrates that the Predictive Risk-Based Regulatory Lifecycle Model (PR-RLM) functions as both an operational optimization tool and a strategic advancement in regulatory governance. By integrating PRRBI-based quantitative scoring, predictive analytics, and reliance mechanisms, the model aligns regulatory oversight with actual product risk, reducing inefficiencies caused by jurisdictional variation. Case-based validation shows that PR-RLM enables reclassification of post-approval changes into proportionate risk tiers, shortening approval timelines and lowering compliance burden. Consistent with principles outlined by the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use guidelines such as ICH Q12 Pharmaceutical Product Lifecycle Management, the model supports harmonized, risk-informed lifecycle management.

ACKNOWLEDGEMENT

I express my gratitude to the Chalapathi Institute of Pharmaceutical Sciences for theirunwavering support, as well as to Ms. Kavya Latha Gunti for his guidance and help in seeing this article through to completion.

Table 1: Comparative Analysis of Post-Approval Change Management Frameworks: Fda Vs Ema

S.No	Parameter	FDA (U.S.)	EMA (Europe)	Implications
1	Post-Approval Change Categorization	CBE, CBE-30, PAS (21 CFR 314.70)	Type I / Type IB / Type II Variations	FDA follows risk-based reporting; EMA categorizes changes formally. Highlights differences in regulatory flexibility.
2	Risk-Based Tools (EC / PACMP)	Implemented in line with Q12 guidance	Implemented under Q12 framework	Both agencies support Q12 adoption; approaches differ in practical implementation.
3	Documentation Requirements	Emphasis on change supplements and narrative justification	Formal variation dossiers with structured tables	EMA generally requires more detailed supporting data, impacting submission preparation.
4	Stability / Lifecycle Submissions	Annual stability reviews; flexible reporting	Type IB/II variations for stability-related changes	Shows differing approaches for post-approval stability management; indicates planning and reporting variations.

Table 2: Comparative Overview of Post-Approval Change (Pac) Frameworks Across Major Regulatory Regions

Region	PAC Categories	Typical Timeline	Strengths	Weaknesses
US (FDA)	PAS, CBE-30, CBE-0, Annual Report	PAS: 6–12 months	Clear risk-based categorization; strong enforcement framework; well-defined reporting system	Longer timelines for PAS approvals; limited procedural flexibility for certain major changes
EU (EMA)	Type IA, IB, II variations	Type II: 6–9 months	Harmonized variation regulation; strong risk-based scientific assessment	Slower adoption of updated ICH guidelines; moderate regulatory agility
Canada (Health Canada)	Level I (major), Level II (minor), Notifiable	6–9 months	Structured framework aligned with ICH; predictable review system	Slower adoption of new ICH guidelines
Australia (TGA)	Risk-based classification	3–6 months	Efficient processing for minor changes; pragmatic regulatory approach	Limited transparency in public assessment reports; reliance on sponsor data
LATAM/APAC	Diverse, country-specific classifications	12–18 months	Gradual adoption of ICH principles in some countries	Lack of harmonization; duplicative submissions; inconsistent risk categorization; extended timelines

Table 3: Comparative Timelines For Major Pac Approvals

Region	Regulatory Authority	Average Approval Timeline (Months)
United States	FDA	10
European Union	EMA	8
Canada	Health Canada	7
Australia	TGA	5
LATAM/APAC	Multiple Agencies	14

Table 4: Example Weighting Schema for Predictive Regulatory Risk Burden Index

Risk Variable	Assigned Weight (%)	Rationale
Impact on Established Conditions	35	Direct influence on regulatory reporting requirements; changes to established conditions (e.g., formulation, manufacturing site) attract highest regulatory attention.
Jurisdictional Complexity	25	Reflects differences in global regulatory expectations; higher complexity increases risk of non-compliance across markets.
Change Criticality on CQAs	20	Changes affecting Critical Quality Attributes (CQAs) directly impact product safety, efficacy, and stability, requiring closer review.
Historical Enforcement Correlation	10	Past enforcement patterns are used to refine risk predictions, highlighting areas where regulatory action is more likely.
Documentation/Data Burden	10	Additional workload from required evidence can delay approvals or increase error risk, representing a secondary but operationally significant factor.

ABSTRACT

Biomedical Signal Processing is playing vital role in modern healthcare system as it helps analyze complex body signals for diagnosing various disease and patient health monitoring. Highly developed medical techniques are in urgent need as healthcare systems globally moves towards predictive, preventive and personalized medicine. Nowadays, pattern-based signal analysis is most widely used than the bio sensors because of its enhanced accuracy, reliability, real time monitoring, and early warning symptoms. This work demonstrates how key signal patterns such as Electrocardiogram (ECG)'s Provocation/Palliation, Quality, Region/Radiation, Severity, Timing (P-QRS-T) complexes and Electroencephalogram's (EEG) alpha, beta, theta, and delta waves can be systematically identified and classified by integrating classical signal processing with modern artificial intelligence. We explore how machine learning models, including Support Vector Machines (SVM), Convolutional Neural Networks (CNN), recurrent neural networks (RNN), and hybrid models, can learn from raw and minimally pre-processed data to achieve superior diagnostic performance. This review examines to capture valid biomedical data with different types of sensors like electrophysiological, optical, biochemical, and imagingg sensors. The real-time, non-invasive monitoring on wearable and implantable devices is supported by these kinds of sensors.

Keywords: Biomedical signals, Pattern analysis, AI, ECG, EEG, CNN, RNN

INTRODUCTION

In modern digital health ecosystem, Biomedical Signal Processing (BSP) plays an important role. Thephysiological signals that require diagnosing, monitor, and treat patients [1] are captured and analysed. The major advancement in the clinical diagnosticc field results in the accelerated technological advancements and a more detailed understanding of human physiology.The is an growing demand for remote healthcare and real-time diagnostic toolsincreases with more advanced and flexible signal processing methods[2][11]. Rapid technological advancements and a deeper insight into human biology are involved in modern times [5][6]. The drawback in the traditionalmethods based on time-domain and frequency-domain methodsis it is unsuccessful to capture parameters of physiological signals [12]. Some of the fields which served a long time in the medical fields are such as subjective analysis, laboratory tests, and periodic health assessments because of some reasons like they are responsive, time-consuming, and require additional resources for data interpretation. Even though the traditional methods are effective in many cases, it is limited in future health prediction, failure of immediate results and cannot fully reflect the dynamic changes of the physiological state of the patient. The digital health technologies and advanced computational techniques create new opportunities in the field of healthcare. A non-invasive or minimally invasive sensor helps in recording and analysing Bio-medical signals. This article helps to understand clearly a stage-wise framework for ECG and EEG analysis, encompassing data acquisition, pre-processing and denoising, feature extraction, and classification [4]. The physiological process produces multiple signals that portray the body's mechanical, electrical, or chemical activities. Electrical signals in the form of potentials or currents, or physical signals like temperature and pressure can occur due to the hormonal and neurotransmitter activity, [13].Some of the bioelectric signals Electrocardiogram (ECG), Electroneurogram (ENG), Electrooculogram (EOG), and Electroencephalogram (EEG). Diagnosing and identifying physiological conditions by detecting meaningful patterns in the signals is known as Pattern-based analysis of biomedical signals and this technique is a branch of Biomedical Engineering and Data Science.

Advanced disease detection, evaluate the effectiveness of treatments, and helps in real-time clinical decision making can be done with this method. While integrated with intelligent sensing systems, the pattern recognition becomeseffective, real-time, and applicable in healthcare solutions. This generates a complete ecosystem as computerized, precise, and adaptable clinical diagnostics [9][10]. The study researches the machine learning models including Support Vector Machine (SVM), Convolutional Neural Network (CNN), Recurrent Neural Network (RNN), and hybrid architecture over techniques. By bridging traditional techniques with AI-driven approaches strengthens diagnostic accuracy. Increasing the precision and performances of biomedical signal interpretation is the primary objective [3]. Overview of pattern-based biomedical signal analysis techniques and intelligent sensor technologies are completely presented in this article. Using the combination of traditional signal processing and artificial intelligence (AI) methods, how signal patterns such as the P-QRS-T complexes in ECG and alpha, beta, theta, and delta waves in EEG can be carefully obtained and classified is the central concern. The transformative impact of intelligent signal analysis systems in clinical settingswill be emphasized in this paper. By combining the potential of pattern-based biomedical signal analysis and advanced sensing technologies, clinical diagnostics can be revolutionized [7][8].The flow of this paper begins with the groundwork for understanding biomedical signals and the various analysis methods,exploring cutting-edge sensing technologies and conclusion of practical diagnostic applications in various clinical field. Ultimately, the paper sketches the future research directions, including edge computing, explainable AI, and standardization of signal acquisition protocols into clinical practice.

Biomedical Signal Analysis: Foundations and Advances

Biomedical signals approach provides a confirmed procedure for detecting clinically-relevant features in physiological signals or pathological states in individuals [14]. Data Acquisition, Preprocessing and noise removal, feature extraction and classification are the outline of this paper for the analysis of ECG and EEG. It also addresses critical obstacles like signal noise, variability across subjects, and imbalanced datasets which can be delayed with the real-world analysis. A biomedical signal is any signal generated by the human body that reflects its biological

processes. These signals can be of various types, such as electrical (e.g., electrocardiogram or ECG), mechanical (e.g., blood pressure waveform), acoustic (e.g., heartbeats), or chemical (e.g., blood glucose levels).

Types of Biomedical Signals

The various biomedical signals and its applications are listed in the Table1. It describes each signal measures and how it is used in diagnostics of diseases.

- **Electrocardiogram (ECG)**: Records the electrical activity of the heart. It is a primary tool in diagnosing arrhythmias, myocardial infarction, and other cardiac conditions. The amplitude of ECG signal ranging from ~0.5 – 5 mV and frequency extending from ~0.05 to 150 Hz**.**

Electroencephalogram (EEG): Measures electrical activity in the brain. EEG is central to diagnosing epilepsy, sleep disorders, and other neurological conditions. Its amplitude ranging between ~10 and 100 μV and it occupies 0.1 to 100 Hz frequency range. This frequency range is commonly divided into delta, theta, alpha, beta, and gamma bands.

- **Electromyogram (EMG)**: Captures muscle activity, useful for assessing neuromuscular diseases. The amplitude of EMG ranging from ~50 μV up to 5 mV, with frequency components fall between 10 and 500 Hz. This is one of the highest-frequency biomedical signals.
- **Photoplethysmogram (PPG)**: Uses light absorption to measure blood volume changes, commonly found in pulse oximeters and fitness trackers. PPG has amplitude range of 0.1 to 3 V and a frequency range of about ~0.5 to 5 Hz.
- **Respiratory and acoustic signals**: Include lung sounds and breath patterns, vital for diagnosing respiratory diseases like COPD and asthma. The frequency range of respiratory signals lies between 0.1 and 0.5 Hz and the frequency range of acoustic signals is much wider than respiratory signals, which is ranging from about 20 Hz to 1000 Hz.

Each of these signals exhibits distinct characteristics in time and frequency domains, which necessitates specialized techniques for processing and interpretation [12].

Signal Processing Techniques

Apart from the raw biomedical data, traditional signal processing approaches use mathematical and statistical tools to pull meaningful information [23]. The fundamental strategy includes:

- **Time-Domain Analysis**: It looks directly at how signal strength changes over time, measures things like peak heights, time between events (like heartbeats), and how quickly signals rise and fall.
- **Frequency-Domain Analysis:** Different states brain waves (EEG) and muscle signals (EMG) show up as distinct frequency patterns. Fourier Transform is used to see which frequencies are present in the signal, especially helpful for identifying.
- **Time-Frequency Analysis**: Tools like STFT and Wavelet Transform combines time and frequency views using essential signals that change their frequency makeup over time, like brain activity or breathing patterns.
- **Nonlinear Methods**: The approaches measure unpredictability patterns in the data. These biological systems are naturally complex.Some techniques like entropy calculations (Approximate/Sample Entropy) and chaos theory concepts are included.

The Fig-1 shows using intelligent sensing and AI technologies analyzing biomedical signals for a five-stage system. The stages are Signal Acquisition, Preprocessing and Denoising, Feature Extraction, Pattern Recognition and Classification and Clinical Decision Support. The wearable or implantable sensors capturing physiological data like ECG, EEG are connected in Signal Acquisition stage [27]. At this stage, the wearable or implantable sensors are capturing the physiological data. In the Preprocessing and Denoising, noises are removed using analog and digital filtering and it corrects the artefacts from motion or signal inconsistencies. Feature Extraction phase identifies key signal-specific features, such as P-QRS-T complexes in ECG or alpha/beta waves in EEG, Pattern Recognition and Classification uses various machine learning models to detect patterns or abnormalities and the Clinical Decision Support stage provides alerts or diagnostic suggestions based on recognized signal patterns. Finally, the

Communication Layer ensures secure transmission and integration using protocols like BLE, Wi-Fi, 5G, and HL7/FHIR for supporting real-time diagnostics and remote healthcare delivery. Recent days, lot of algorithms introduced to improve diagnostic accuracy and robustness. The deep learning based algorithms are using the techniques called CNN to capture local temporal patterns. RNN and LSTM techniques are used in ECG rhythm analysis and EEG sleep stage classification. 1D-CNN, ECG-Transformer, DCNN, TCN are the example for these type of algorithms [33][34]. Algorithms namely, EMD, EEMD, CEEMDAN, and VMD are the self-supervised and transfer learning algorithms. The self-supervised technique solves the unlabelled data issues and the transfer learning enhances the performance and improves generalization [35]. In Graphical Neural Networks (GNN), electrodes are modelled as nodes to capture spatial brain connectivity in EEG analysis. The explainable artificial intelligence (XAI) technique is integrated with deep learning model to improve transparency and clinical trust, particularly cardiac diagnosis [36]. Examples for this type of algorithms are GAT and Grad-CAM.

Pattern Recognition and Machine Learning

As technology continues to progress rapidly and our understanding of human physiology becomes more complete, there will be significant advancements in the manner in which clinical diagnostics occur. Simply put, clinical diagnostics (CD) is a systematic way of finding diseases, conditions, and injuries based upon the signs, symptoms, medical history, and physical examinations of patients, and because there is an increasing rate of growth in patients with chronic diseases as well as a greater demand for high-quality care [15]. Commonly used machine learning methods include:

- **Supervised Learning**: Algorithms like Support Vector Machines (SVM), Random Forests, and Neural Networks are trained on labelled datasets to classify physiological states (e.g., normal vs. arrhythmic ECG).
- **Unsupervised Learning**: Techniques like K-Means and DBSCAN help discover clusters or latent structures in unlabeled signal data, useful in exploratory studies or anomaly detection.
- **Deep Learning**: Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) can learn hierarchical features from raw signals without manual feature engineering. They are remarkably useful in ECG and EEG interpretation.
- **Hybrid Models**: ML allows for robust, real-time systems by combining signal processing. CNN classification improves both interpretability and accuracy.

The features from biomedical signals are extracted through feature extraction technique before implementing ML models. The common characteristics are time-domain, frequency-domain, and time-frequency. The model can be trained with the help of predefined models such as SVM, Random Forest etc., to recognize the pattern after the features are extracted,.

Intelligent Sensing Technologies

The new generation of intelligent sensing platforms increased to the rapid evolution of sensor technologies and embedded systems. These devices perform preliminary data analysis and transmitting actionable insights to healthcare providers in real time other than capturing high-quality biomedical signals [32]. Making critical to any integrated clinical solution, intelligent sensing technologies serve as the physical interface between the human body and digital diagnostic systems, The Fig-2 illustrates how to enable sensors for proactive and efficient healthcare delivery, artificial intelligence, cloud analytics, and user interfaces combined together. Bio signals are directly captured from the body by the Intelligent Sensor Nodes which are used for uninterrupted health monitoring. Local (Edge) Processing is a Lightweight on-device processing, it performs filtering, noise suppression, and feature extraction tasks. Cloud Computing Infrastructure dealt with data which is sent to the cloud for in-depth analysis using powerful AI models such as CNNs, LSTMs, and hybrid systems. These models process large volumes of data to detect patterns, trends, or risks. Healthcare Provider Interface act as a mediator between doctor and patient for accessing the data through Electronic Health Records (EHRs), Clinician dashboards, Remote care apps, Enables real-time alerts and decision support.

Types of Intelligent Sensors in Healthcare

Modern intelligent sensors are designed to be wearable, non-invasive, and energy-efficient, allowing continuous and long-term monitoring [16][7]. Major categories include:

Wearable Sensors

The wearable sensors are embedded into accessories such as smart watches, chest straps, or clothing. Examples include: Electrodes for ECG or EMG monitoring, Photodiodes and LEDs for PPG-based pulse monitoring, Inertial Measurement Units *(IMUs)* for motion analysis and fall detection. In a recent study, Apple watch ECG data is combined with a deep learning algorithm to detect structural heart disease successfully. The accuracy of disease prediction and cardiac screening is extending the clinical environment [37]. The smart watch equipped with single-lead ECG sensors continuously monitoring the cardiac health along with the AI algorithms. These algorithms filter noise as well as detect arrhythmias. Blood Pressure Monitoring: Hypertension is a genuine hazard factor that may prompt coronary episodes or strokes. Blood flow may differ from minute to minute and continuous monitoring of blood pressure by medical sensors helps the patients for being able to know their health's status. In [38], a Blood Pressure Monitoring is proposed. The system consists of two ends called sensing-end and server-end. The sensing-end made up of wearable sensors which can monitor blood pressure and Internal Measurement Unit (IMU) that can provide a correlation between sensed data and its physical movement. The server-end provides management of network function, processing and analyzing the raw sensed data. By using sensed blood pressure data and IMU data, feature matrix vectors can be constructed. The system utilizes regression based algorithm such as KNN, SVM, Bayesian etc., to predict the future values of blood pressure measurements. The users and doctors can simultaneously access the data analysis and working status.

Implantable Sensors

Implantable sensors are integral part of modern healthcare systems which continuously monitoring the human health system without any restriction. These sensors can be used for chronic disease monitoring, such as glucose sensors implanted under the skin or pacemakers with telemetry, electrocardiogram, and respiratory rate [39]. These kinds of sensors are adopting Micro Electro Mechanical Systems (MEMS) based technologies to achieve continuous, real-time monitoring of patients health condition and the ability to get help when a critical event occurs.

Environmental and Ambient Sensors

Internet of Robotic Things (IoRT) employs various on-body, off-body and ambient sensors to get real-time information from individuals, with robotic systems used to provide assistance with daily activities, critical and emergency events [40]. It monitors the activity and fitness of in-home inhabitants [41]. These sensors also measure room temperature, humidity or air quality in smart hospital or home care setups to support diagnostics indirectly.

Signal Acquisition and Pre-Processing

The signal acquisition can achieved through various techniques, such as electrode, sensors, Imaging Modalities etc. Acquiring clean, usable signals from the human body is a non-trivial task due to interference from motion artifacts, electrical noise, and physiological variability [17]. Pre-processing is an important phase aimed at enhancing signal quality and preparing it for further analysis. The main steps include filtering, normalization and segmentation. Intelligent sensing systems include several layers of signal conditioning:

Analog Front-End (AFE) Circuits

The amplification and filtering of weak physiological signals (e.g., mV-range ECG signals) and it is the interface between the human body and digital processing systems. The main elements of AFE are Instrumentation Amplifiers (INA), Programmable Gain Amplifiers (PGA) and Anti-Aliasing Filters.

Digital Filtering

Residual noise is filtered, removed and clinically relevant information are extracted. Due to its flexibility, stability, and ease of reconfiguration nature the digital filters are recommended. Most of the algorithms include for power line interference notch filters, to isolate physiological frequency ranges band pass filters, and for noise suppression adaptive filters are used.

Signal Normalization

It ensures consistency across different recordings, devices, and subjects and it is an important preprocessing step. It ensures consistency in the amplitude of the signal and baseline, and facilitating accurate downstream analysis.Min–Max Scaling, Z-Score Normalization and Baseline Correction are the most common normalization technique.

Artefact Detection and Correction

Machine learning-based techniques can identify and discard corrupted segments of data (e.g., those affected by motion or poor sensor contact). Rule-Based Detection, Machine Learning-Based Detection, Signal Decomposition Methods, Segment Rejection or Reconstruction are the Modern artifact handling techniques used in biomedical signal processing. For example, in wearable ECG monitoring, deep neural networks can automatically detect motion artifacts caused by physical activity and either correct or exclude affected segments before arrhythmia analysis.

Edge vs. Cloud-Based Processing

A crucial design decision in intelligent sensing is whether to process data locally (on the device or nearby "edge" device) or to transmit it to the cloud for analysis. Two common types of computing are Cloud Computing and Edge Computing. With Cloud Computing, we send all of our data to a centralized server that has access to a very large amount of computer processing and storage. Complex analyses, including but not limited to Machine Learning, can be performed remotely. Cloud Computing can often result in latency and connectivity issues [5]. With Edge Computing, we perform all of our processing locally using microcontrollers or embedded processors and send data to the cloud for only complex analyses [9]. Because we can process data locally, Edge Computing allows for power efficiency, improved privacy, and better performance for latency-sensitive applications (e.g. seizure prediction/arrhythmia detection). When combined, we can perform pattern detection on the edge and conduct more sophisticated analytics in the cloud. This allows for a greater degree of responsiveness to real-time events, while also providing enhanced capabilities for advanced analytics.

Communication Protocols and Interoperability

To enable integrated healthcare systems, intelligent sensors must communicate seamlessly with other devices and platforms. This requires to following certain uniform guidelines:

Bluetooth Low Energy (BLE)

Due to its ultra-low power consumption and native support in smartphones and tablets, it is one of the most widely adopted protocols in wearable healthcare systems. It is widely used in fitness trackers, ECG patches, and smart watches, which allow real-time data synchronization with mobile health applications.

Zigbee

Zigbee is also low-power standard which is suitable for multi-sensor healthcare environments to communicate consistently with a central coordinator with minimal power consumption.

High-Throughput Communication

Wi-Fi and 5Gare high-throughput real-time data streaming in clinical settings.Wi-Fi because of its high data rates and established infrastructure is widely deployed in hospitals and clinical settings. To ensure Quality of Service (QoS) and prevent interference with other critical medical devices Wi-Fi networks must be carefully managed. 5G offers extremely fast response time, high reliability, network slicing for medical-grade communication and ability to connect a very large number of devices simultaneously.

Interoperability Standard

The data exchanged between systems can be consistently interpreted and clinically meaningful, beyond connecting devices physically in the health care system through HL7 and FHIR standards.It ensures meaningful data exchange with electronic health records (EHRs)[18]. Flawless, secure, and meaningful data exchange across the healthcare management are enabled byHL7 and FHIR. To ensure continuous and secure operation, the design of robust communication systems must also consider data encryption, authentication, and failover mechanisms.

Integrated Pattern-Based Diagnostic Models

When pattern-based signal analysis is deeply integrated with intelligent sensing hardware, a revolutionary diagnostic tool can be developed. Independent of manual control, the collaboration enables end-to-end systems [19] that can persistently acquire, analyse, understand, and act upon biomedical data.

Architecture of Integrated Diagnostic Systems

Components of Architecture of Integrated Diagnostic Systems are [27]:

- **Signal Acquisition Layer**: Wearables or implantable continuously capture biomedical signals.
- **Preprocessing Layer**: Filters, normalizes, and digitizes signals for analysis.
- **Feature Extraction Layer**: Converts signals into meaningful features (e.g., heart rate variability, EEG rhythms).
- **Pattern Recognition Layer**: Uses machine learning or deep learning models to identify health states or anomalies.
- **Decision Support Layer**: Maps patterns to diagnostic recommendations, alerts, or therapeutic interventions.
- **Communication Layer**: Transmits data to healthcare providers or cloud repositories as needed.

Machine Learning Frameworks for Pattern Recognition

Several ML and AI models are commonly used for biomedical signal classification and prediction [20]:

- **Support Vector Machines (SVM)**: Good for high-dimensional, small-sample problems. Widely used in ECG classification.
- **Random Forests**: Excellent for handling missing data and feature importance ranking.
- **Convolutional Neural Networks (CNNs)**: Effective for spatial pattern detection in signals visualized as images or spectrograms.
- **Recurrent Neural Networks (RNNs)** and **Long Short-Term Memory (LSTM)** networks: Suitable for time-series data like EEG and respiratory waveforms.
- **Transformers**: Recent advances in attention-based models allow for powerful sequence modeling with improved context retention.

The Table 2 shows a concise comparison of commonly used machine learning models in biomedical signal analysis.

Real-World Examples

Example 1: Arrhythmia Detection from ECG

An integrated wearable device captures ECG signals continuously. An embedded CNN model processes the data in real-time to detect irregular heartbeats. When arrhythmia is detected, an alert is sent to a smartphone app and the data is uploaded to the cloud for cardiologist review.

Example 2: Epileptic Seizure Prediction Using EEG

A scalp EEG headset uses a hybrid LSTM-Wavelet model to forecast seizure onset based on patterns of brain activity. When high-risk states are detected, the system triggers a warning signal, allowing patients to take preventive action.

Example 3: Respiratory Distress Monitoring in ICU

Oxygen saturation (SpO2), respiration rate, and heart rate are measured by a sensor suite. Using real time, the danger of respiratory failure is identified and suggests caregivers for ventilator adjustments or alerts for immediate treatment.

Applications in Clinical Domains

The combination of pattern-based biomedical signal analysis and intelligent sensing technologies is becoming a vital innovation across several medical specialities. The patient outcomes have improved which results in reducing healthcare costs and enabling more proactive care by enabling real-time, personalized, and context-aware diagnostics.

Let us explore the some of the core areas where these technologies have shown their significant impact.

- Cardiovascular Health Monitoring
- Neurological Disorders and Brain Health
- Respiratory and Pulmonary Care
- Metabolic and Endocrine Monitoring
- Metabolic and Endocrine Monitoring
- Emergency Medicine and Critical Care
- Remote Patient Monitoring and Telehealth

Challenges and Opportunities

Due to some obstacles connected with it, quick development of patterns of integrated signature analysis connected with the algorithms and systems are evolved. These issues should be tackled by taking necessary steps for implementing innovative, ethically deployed and clinically significant systems. Biomedical signals are extremely affected by noise, motion artifacts, and unpredictability because of physiological and environmental factors. Unreliable data reduces the quality of diagnostic algorithms' performance, which results in non-identified medical conditions or false positives. Limitations with data quality and fluctuations have to be handled in order to enable the existence and to increase the AI-generated physiological processes. Unsuitable hardware, software, and data formats are often used in health care systems [32]. The lack of consistent rules or formats slows down the integration across systems and complicates the operation of intelligent sensing solutions. Real time observation raises concerns about data ownership, consent, and protection against breaches or misuse [21] (e.g., insurance discrimination). Due to limited applicability and legal and challenges many AI-driven diagnostic tools excel in controlled trials but struggle in real-world settings. Implementing these technologies in low-resource settings is limited by cost, connectivity, and computational constraints.

Machine learning (ML) has improved filters that changes or adapts to different noise characteristics automatically according to the noise conditions are known as adaptive noise cancellation. Generative adversarial networks (GANs) can make something better in quality strength by generating realistic noisy-clean signal pairs. Signal Quality Indices (SQIs) are used to point out or reject inaccurate segments by combining real-time quality assessment into processing pipelines. IEEE 11073 for device communication and HL7 FHIR for EHR for different systems to work together are used for open standards. Tools that connect between protocols are Middleware solutions, Mirth Connect. Modular architectures, which use micro services and APIs are Plug-and-play by which integration is possibly made. Using processed data, Federated Learning (FL) allows ML models to be trained without sharing original or unprocessed data. Blockchain-based audit trails are fixed records that provide transparency in data access and usage. Differential privacy is the process of preventing re-identification by introducing statistical noise into datasets. Real-world evidence (RWE) stands for real-world evidence, which is derived from digital heath system and sensor derived data. Agencies supervise there gulatory sandboxes which are having regulated validation test beds. The coordinated framework can accelerate data validation [22].

CONCLUSION

The integration of pattern-based biomedical signal analysis with advanced sensing technologies is revolutionizing clinical diagnostics. It transforms healthcare from a reactive, continuous, active and personalized. Machine Learning and Deep Learning allows for timely, accurate and patient specific diagnoses are made by modern sensors such as

wearable, environmental etc which collect detailed health data. From basic observation to deep understanding, this method guide for preventive and immediate care. AI generated healthcare systems can improve the accuracy of diagnosis, clinical workflow optimization and reduces cost by providing proactive and patient specific care and integrating intelligent sensors with BSP. This advance method supports for personalized, proactive healthcare using continuous monitoring and early interventions. Finally, the goal of this is designed to improve the patient health more personalized and efficient

Emerging Trends and Future Directions

Even though there are many challenges combination of formal document regarding diagnostics are vivid. This will make an impact a change in health care in future [26] [27]:

- **Multimodal Data Fusion:** Measurements from multiple bio signals can be integrated (e.g., ECG, EEG, PPG) and information (e.g., activity, location) for health care diagnostics.
- **Medical Digital Twins:** The concept enables to simulate and extrapolate patients' physiology systems based on data collected from them.
- **Neuroadaptive and Closed-Loop systems:** Based on EEG patterns, systems actively modify therapeutic solution according to real-time feedback, such as brain stimulation.
- **Next Generation Sensors:** These are related to the development of flexible stretches, ingestible sensors 8 and advanced biochemical sensors to monitor hormones or metabolites.
- **AI-Powered Clinical Decision Support:** Deploying AI to assist.

Table 1 : Biomedical Signals and Diagnostic Applications

Signal Type	Measured Activity	Primary Diagnostic Applications	Typical Sensors
ECG	Electrical activity of the heart	Arrhythmia detection, myocardial infarction, heart rate variability	Electrodes, wearable chest straps
EEG	Brain's electrical activity	Epilepsy, sleep disorders, cognitive impairment	Scalp electrodes, headbands
EMG	Muscle activity	Neuromuscular disorders, prosthetic	Surface or needle

		control	electrodes
PPG	Blood volume changes	Heart rate, oxygen saturation, stress level monitoring	Optical sensors, pulse oximeters
Respiratory Signals	Airflow and lung sounds	COPD, asthma, sleep apnea	Microphones, airflow sensors

Table 2: Machine Learning Models for Biomedical Signal Classification

Model Type	Typical Use Case	Advantages	Limitations
SVM (Support Vector Machine)	ECG arrhythmia classification	Works well with small datasets, good generalization	Limited scalability, manual feature selection needed
CNN (Convolutional Neural Network)	EEG/ECG image Or spectrogram analysis	Learns spatial features automatically	Requires large datasets, high computational cost
RNN / LSTM	Time-series EEG/respiratory signal prediction	Captures temporal dependencies	Prone to vanishing gradient, slower training
Random Forest	Multimodal biosignal fusion	Handles noisy data, interpretable	May underperform with temporal data
Hybrid (CNN + LSTM)	Complex signal recognition	Combines spatial and temporal learning	Complex training pipeline

ABSTRACT

Xerostomia is a complex condition that is becoming more common in the elderly population due to several causes ranging from developmental to iatrogenic. Pharmacological treatment improves the symptoms but increases the adverse effects of the latter and worsens the situation again. Keeping this in mind, non-pharmacological interventions are currently used or under supervision to bypass the complications of pharmacological treatment. This article aims to review the prevalence, incidence, causes, signs/symptoms, and most importantly the success rate of non-pharmacological interventions. Articles in PubMed, Cochrane database, and Web of Science were analysed till date to establish the effectiveness of different modalities such as acupuncture, electrostimulation, hyperbaric oxygen (HBO) therapy, and low-level laser therapy (LLLT), etc. Newer treatment modalities such as gene therapy is under trial. This paper provides a broad idea of the different non-pharmacological interventions currently used and our newer future for treating dry mouth.

Keywords: Acupuncture, Electrostimulation, Gene therapy, HBO therapy, LLLT.

INTRODUCTION

Xerostomia (Dry Mouth)

The concept of dry mouth was first described by Bartley in 1868, and later the term xerostomia was introduced by Hutchinson in 1889. According to Sreebny (1988), xerostomia refers to the subjective sensation of oral dryness, which is commonly associated with reduced salivary gland function [1]. Although this condition is more frequently observed in older individuals, it should not be considered a normal consequence of aging [1]. Xerostomia can also occur in younger populations, including adolescents, though it is relatively uncommon in children. Under normal conditions, the unstimulated salivary flow rate is approximately 0.3 mL/min. During sleep, it decreases to around 0.1 mL/min, while stimulation such as chewing can increase the flow rate to about 4–5 mL/min [1]. The prevalence of xerostomia is estimated to be between 14% and 35%, and its occurrence has been increasing, particularly in developed countries [1].

Causes of Xerostomia

In most cases, dry mouth results from salivary gland hypofunction, which may be temporary or long-term. This condition may or may not be accompanied by the subjective feeling of dryness **[3]**.

A major cause in older adults is the use of medications that reduce saliva production **[3]**. These include:

- Anticholinergics
- Sympathomimetic drugs
- Sedative-hypnotics
- Opiates
- Antihistamines
- Muscle relaxants

Other important causes include:

- Radiation therapy, especially in patients treated for head and neck cancers **[15]**
- Autoimmune disorders, such as Sjögren's syndrome **[3]**

In some situations, patients may report dryness even when salivary flow is not significantly reduced.

Management

Despite the wide range of causes, the management of xerostomia is generally similar across cases. An exception is drug-induced xerostomia, where treatment involves stopping the offending medication or replacing it with an alternative that has fewer drying effects **[3]**. At present, there is no single definitive treatment that is effective for all cases of xerostomia. Xerostomia can be managed using two broad approaches: pharmacological and non-pharmacological methods. Pharmacological therapies mainly provide temporary symptomatic relief, and symptoms often return once the medication is discontinued. In contrast, newer non-pharmacological approaches aim to enhance natural salivary secretion and provide more sustained improvement. In recent years, these alternative methods have gained attention due to their effectiveness in alleviating symptoms associated with dry mouth **[2,7]**.

Acupuncture

Acupuncture is a therapeutic technique that involves inserting very fine needles into specific points within or beneath the skin and is widely used for various conditions **[4,5]**. Its effectiveness in symptom control and supportive care has been documented **[6]**. The mechanism by which acupuncture improves salivary flow is not fully understood, but it is thought to stimulate autonomic pathways and enhance glandular function. Acupuncture is considered a low-risk therapy with minimal adverse effects **[7,8]**.

Transcutaneous Electrical Nerve Stimulation (TENS)

TENS is a physical therapy that delivers low-voltage electrical impulses through electrodes placed on the skin **[9]**.

Mechanism in Xerostomia

TENS may stimulate salivary secretion through neural reflexes. Extraoral application activates the auriculotemporal nerve, which transmits signals to the salivary center in the brainstem, initiating salivation **[10]**.

Intraoral stimulation activates sensory pathways in the oral mucosa, increasing salivary output. A frequency range of 50–80 Hz applied for 5–10 minutes is considered effective and safe **[11]**.

Low-Level Laser Therapy (LLLT)

Low-level laser therapy (photobiomodulation) uses low-intensity light to stimulate cellular activity. It enhances ATP production, promotes tissue repair, and improves salivary gland function.

Studies have demonstrated improved salivary flow following LLLT **[12,13]**. However, further research is needed to determine optimal treatment parameters **[14]**.

Hyperbaric Oxygen Therapy (HBOT)

Hyperbaric oxygen therapy improves oxygen delivery to tissues and is especially useful in radiation-induced damage. It promotes angiogenesis, collagen synthesis, and tissue repair **[15,16]**.

HBOT has been shown to improve salivary gland function and quality of life in affected patients **[17,18]**.

Gene Therapy

Gene therapy aims to restore salivary gland function by introducing genes such as AQP1 to improve fluid secretion. Experimental studies have shown promising results in restoring gland function **[19]**.

It may also reduce inflammation and protect glandular tissue in autoimmune conditions **[20]**.

CONCLUSION

Xerostomia remains difficult to manage. Pharmacological therapies provide temporary relief, whereas non-pharmacological methods such as acupuncture and TENS show beneficial effects.

Advanced therapies like LLLT and HBOT improve glandular activity, while gene therapy offers future potential. Continued research is required to establish effective long-term treatments.

ABSTRACT

The accurate and timely detection of brain tumours is necessary for better treatment planning and improved survival rates. This study proposes a deep learning architecture with attention enhancement for brain tumour classification using MRI images. An improved version of the EfficientNetV2 is proposed using attention mechanisms to identify specific tumour locations while suppressing irrelevant background data. MRI images are collected from a Kaggle public domain dataset and are preprocessed for standardization and augmenting the data. The model offers improved feature extraction, multiscale learning, and robust classification for brain tumours. Evaluation through experiments shows promising prediction capabilities with 98.23% accuracy, 96.49% precision, 96.46% recall, and an F1-score of 96.48%. From the results, it can be concluded that the architecture performs consistently and reliably compared to traditional CNN architectures. The approach decreases the dependency of humans in diagnosing brain tumours using MRI images. The presented model offers a scalable and reliable solution for identifying brain tumours with MRI using computers, which could be helpful for doctors in practice environments.

Keywords: Brain tumour classification, Magnetic Resonance Imaging, EfficientNetV2, Attention mechanism, Deep learning

INTRODUCTION

Brain tumours, affecting both kids and adults, can result in morbidity and fatalities when not diagnosed early enough. Brain tumours refer to abnormal growth of cells in the brain and nearby structures, affecting cognitive function, movement, and sensory processes. Benign, malignant, and pituitary tumours vary in their methods of growth, hazards, and treatment options. It is important to diagnose brain tumours at an early stage to plan treatment and improve life expectancy. MRI is the superior imaging method for brain tumours because of its soft tissue contrast and non-invasiveness. MRI shows cancer size, location, and structure without radiation. The growing amount of clinical MRI data burdens radiologists. Tumours with varied forms, indistinct borders, and intensity changes are difficult to interpret manually and vulnerable to observer variability. These concerns drive reliable, automated computer-aided diagnostic methods. It presents an Attention-Enhanced Brain-EffNetV2 framework for MRI-based brain tumour classification.

The proposed method improves discriminative feature learning by integrating channel and spatial attention modules with EfficientNetV2. The framework attempts to achieve high classification accuracy and computing efficiency via efficient architectural design and attention-guided refinement. The method helps radiologists reduce diagnostic burden and unpredictability by making reliable and automated predictions. Variable tumour form, similarities between malignant and healthy tissues, inadequate annotated datasets, and different MRI collection techniques make brain tumour classification difficult. Expert radiologists are few in many healthcare settings, particularly in underdeveloped countries, making diagnosis more difficult. Fast, objective, and repeatable analysis from automated deep learning systems can solve these problems. Most models give preference to accuracy over computations or fail to focus on tumour-related regions. An efficient attention-based framework enables a model to learn useful representations without being complex. The Brain-EffNetV2 framework was designed based on this concept. The summarization of the contribution is as follows:

- Proposed an attention-enhanced Brain-EffNetV2 architecture is proposed for MRI-based brain tumour classification.
- Integrated channel and spatial attention mechanisms to improve tumour-focused feature representation.
- Adopted EfficientNetV2 as a lightweight yet powerful backbone for efficient deep feature extraction.
- Designed a robust preprocessing pipeline including normalization and augmentation to enhance generalization.
- Developed an automated classification framework that reduces reliance on manual MRI interpretation.
- Demonstrated strong performance across evaluation metrics, indicating reliability for clinical support.

The study is segmented into four parts. The second part includes the literature review as well as background of brain tumor classification and deep learning systems. The third part involves a description of the proposed model named 'Proposed Brain-EffNetV2'. The fourth section focuses on experimental results and their evaluation.

Related Works

One study evaluated smartphone-based MRI image processing for brain tumour classification was examined in [1]. The hybrid deep learning architecture classifies brain tumours from MRI images using CNN, Vision Transformer (ViT), and MobileViT models. Transfer learning improves pretrained networks like VGG16, ResNet152V2, InceptionV3, InceptionResNetV2, and MobileNetV2. All models are trained in TensorFlow, assessed similarly, transformed to TensorFlow Lite, and incorporated into a Flutter-based mobile app for on-device inference. Brain tumour classification and diagnosis using hybrid deep-classical models was detailed in [2]. A Hybrid Deep–Classical Model combined deep CNN feature extraction with machine learning classifiers. Pretrained CNNs like VGG16, ResNet50, and DenseNet121 retrieve deep features from pre-processed MRI images without terminal layers. PCA reduces traits and SVM, Random Forest, and KNN classify them, with SVM performing best. Summary of Federated Learning Combined Ensemble Aggregation for MRI Brain Tumour Classification was summarised in [3]. A federated learning brain tumour classification system using CNNs and ensemble aggregation is presented. Each client (medical facility) trains an identical convolutional neural network model on its MRI data and sends just the weights to a

central server. A meta-learner allocates appropriate weights to client models according on validation performance, while the server consolidates them using weighted averaging to create a global model. The classification of brain tumours using MRI using dilated SE-DenseNet was examined in [4]. The proposal involves an improved DenseNet-121 architecture that incorporates dilated convolutional layers to broaden the receptive field and Squeeze-and-Excitation (SE) attention modules to adjust channel-wise features. The integrated Dilated SE-DenseNet model enhances feature representation and classification efficacy for brain tumour identification from MRI scans.

A hybrid explainable model for brain cancer classification using MRI images and advanced machine learning and deep learning techniques was summarised in [5]. A hybrid PDSCNN–RRELM architecture that integrates a Parallel Depthwise Separable CNN for feature extraction with a Ridge Regression Extreme Learning Machine for classification, augmented with CLAHE preprocessing and SHAP-based explainability. Hybrid deep learning algorithms were used to classify brain tumours using T1-weighted MRI in [6]. It utilises a hybrid deep learning framework that integrates a U-Net architecture with transfer learning-based CNNs, notably InceptionV3, EfficientNetB4, and VGG19. Pretrained ImageNet weights are refined, the Flatten layer is substituted with Global Average Pooling, and bespoke dense layers using SoftMax are included for multiclass brain tumour classification. The use of pre-trained deep convolutional neural network models with transfer learning for sophisticated brain tumour classification in MRI images was elaborated in [7]. It employs a transfer learning-based deep learning methodology using several pre-trained CNN architectures, including Xception, MobileNetV2, InceptionV3, ResNet50, VGG16, and DenseNet121. Models trained on ImageNet are fine-tuned using brain MRI images for four-class tumour classification, using bespoke fully connected layers for feature adaption and employing SoftMax for prediction.

A novel cognitive computational approach for brain tumour classification using MRI data has been proposed in [8]. A hybrid Particle Swarm Optimisation - Quantum-Enhanced Support Vector Machine (PSO-QESVM) framework for the classification of brain tumours from MRI images was proposed. Images are first denoised with a median filter. Deep features are derived via ResNet and VGG16 convolutional neural network models. The features are classified using a QESVM, with hyperparameters appropriately adjusted by PSO to enhance accuracy and resilience. The optimisation of CNN architecture for MRI brain tumour classification using PSO was examined in [9]. It uses a PSO-based automated CNN architectural search, whereby PSO dynamically optimises the quantity of layers, filter dimensions, and neurones to construct an effective convolutional neural network for MRI brain tumour classification. The classification of brain cancer MR images with a hybrid quantum graph neural network was proposed in [10]. A Hybrid Quantum Graph Neural Network (QGNN) is presented for the classification of brain tumours using MRI images. Images are first transformed into graph representations and then analysed using a standard Graph Convolutional Neural Network (GCNN). A quantum layer using parameterised quantum circuits is then included to encode PCA-reduced features into quantum states, execute quantum rotations and entanglement, and derive quantum node embeddings, which are then processed by classical dense layers for ultimate classification. The classification of brain tumours using MRI with a ResNet50 Spatial Transformer Network including a Non-Local Attention Mechanism (STN-NAM) is reported to be accurate in [11]. U-Net is first used to delineate tumour locations from MRI scans. The STN module enhances spatial invariance through the acquisition of geometric changes, whilst the NAM identifies long-range relationships between lesion and normal regions, enabling more precise brain tumour categorisation. A collaborative federated learning approach for brain tumour classification using explainable AI in medical imaging was shown in [12].

The research proposed an XFL architecture that incorporates a pretrained GoogLeNet CNN for the classification of brain tumours from MRI images. Numerous clients locally train GoogLeNet models using decentralised data, while a central server consolidates updates through Federated Averaging. Model interpretability is improved using Grad-CAM and Saliency Maps to visualise areas pertinent to decision-making. A strategy for real-life scenario simulation and augmentation to enhance MRI brain tumour classification has been proposed in [13]. A deep learning framework using transfer learning and fine-tuning with several pretrained CNN and ViT models was implemented. Architectures including DenseNet, EfficientNetV2, ResNet, VGG, ConvNeXt, and ViT were assessed, with

EfficientNetV2-B0 identified as the optimal model. Gaussian noise and blur augmentation replicate real-world MRI settings and improve robustness and generalisation. Neural network methods for MRI brain tumour classification were improved in [14]. A customised sequential CNN is employed for multiclass brain tumour classification from MRI data. Images are scaled, normalised, converted to greyscale, and supplemented. The CNN comprises sequential Conv2D layers (64–256 filters), each succeeded by max-pooling and dropout, followed by fully linked dense layers with a SoftMax output. Grad-CAM is included to enhance the visual interpretability of model judgements. An improved CNN hyperparameter model enhances the accuracy and reliability of brain tumour diagnostics, as shown in [15]. This method presented an HPCNN for the classification of brain tumours using MRI images. A unique CNN architecture is constructed and methodically refined by adjusting critical hyperparameters, such as the quantity and dimensions of filters, stride, padding, pooling type, activation functions, learning rate, batch size, layer count, dropout rate, and optimiser SGD/Adam. Random search is used to ascertain the optimal arrangement. A self-attention-based progressive generative adversarial network using a momentum search approach for brain cancer MRI classification was presented in [16]. A self-attention-based Progressive Generative Adversarial Network (SPGAN) optimised using a Momentum Search Optimisation Algorithm (MSOA) for the classification of brain tumours from MRI images. Noise is mitigated using ADKF, texture features are obtained by TP-DWT, and SPGAN executes classification with parameters optimised by MSOA for enhanced accuracy and convergence.

A hybrid deep convolutional neural network model for brain tumour image classification was developed in [17]. A hybrid deep convolutional neural network framework with three bespoke CNN architectures for the classification of brain tumours from MRI images. The first CNN executes binary tumour identification, the subsequent one manages five-class tumour type classification, and the last CNN classifies gliomas into three classes. Grid search optimisation systematically adjusts architectural and training hyperparameters. The models use stacked Conv–ReLU–Pooling layers, succeeded by fully connected and SoftMax layers for prediction. The study presents effective ensemble frameworks for predicting human brain tumours from MRI scans [18]. A hybrid ensemble architecture combining CNN and machine learning for the classification of brain tumours from MRI images. Deep features are obtained by a customised CNN, thereafter, subjected to PCA for dimensionality reduction. The diminished characteristics can be classified using several machine learning models such as AdaBoost, XGBoost, Random Forest, KNN, Decision Tree. An ultimate ensemble voting model (XG-Ada-RF) amalgamates predictions from AdaBoost, XGBoost, and Random Forest to enhance accuracy. A robust deep learning model for brain tumour classification using reconstruction and fine-tuning was presented in [19]. A transfer learning framework augmented by reconstruction for the classification of brain tumours using MRI images. The quality of the image is first enhanced by a deep reconstruction network. The reconstructed images are further refined with several pretrained CNN models, such as VGG16, VGG19, ResNet50, ResNet101, DenseNet121, DenseNet169, InceptionV3, InceptionResNetV2, Xception, MobileNetV2, and EfficientNet-B0. Layer-wise fine-tuning and optimised training configurations are used to enhance classification accuracy and resilience. A sophisticated brain tumour identification technique using deep convolutional neural networks was presented in [20]. A CNN-based framework for brain tumour diagnostics with EfficientNetV2 and optimised with the Ranger optimiser. MRI images are subjected to clipping, denoising, and histogram equalisation, subsequently accompanied by restricted data augmentation. EfficientNetV2 executes tumour identification and classifies tumours into three distinct groups such as glioma, meningioma, and pituitary. Transfer learning with ImageNet weights is implemented, and Ranger enhances convergence stability and generalisation.

PROPOSED METHODOLOGY

The Proposed system introduces an Attention-Enhanced Brain-EffNetV2 framework for accurate and reliable multi-class brain tumour classification from MRI data. The framework is designed to classify MRI brain images into four clinically relevant classes: glioma, meningioma, pituitary tumour, and normal brain. End-to-end image classification with the Proposed method facilitates automated disease diagnosis using low computational costs, unlike other approaches relying on segmentation. This system entails the following critical components:

- MRI preprocessing
- A Brain-EffNetV2 network backbone adaptation.
- Improving feature discrimination through lightweight attention techniques.

With this combination, the model enhances class separability and generalization ability, especially in situations where the amount of training data is scarce. Firstly, brain MRIs are normalized to maintain uniformity for training purposes. Every brain MRI undergoes resizing to 224 x 224 pixels while maintaining a grayscale format. Normalization of intensity is conducted in order to mitigate intensity differences owing to varying imaging conditions. Normalization can be described as

$$I_{norm} = \frac{I-\mu}{\sigma} \qquad (1)$$

where I the input MRI image, μ the mean intensity value, σ the standard deviation.

Brain-EffNetV2 Feature Extraction

The suggested framework uses the modified version of EfficientNetV2 for feature extraction at multiple levels from MR images. The structure consists of a 3 × 3 convolution layer that is used to extract low-level spatial features like edges. The convolution operation is defined as

$$F_{i,j} = \sum_m \sum_n I_{i+m,j+n} \cdot K_{m,n} \qquad (2)$$

where I represents the input feature map, K denotes the convolution kernel, $F_{i,j}$ represents the extracted feature map. i is row index of the output feature map, j is column index of the output feature map, m is row index of the convolution kernel, n is column index of the convolution kernel. Following the convolution layer, the network uses Fused-MBConv blocks in the early stages to improve computational efficiency and reduce training time. These blocks combine convolution and expansion operations into a single operation. In deeper layers, MBConv blocks with Squeeze-and-Excitation (SE) modules are used to capture high-level semantic information. Figure 1 illustrates the architecture of the Attention-Enhanced Brain-EffNetV2 model designed for automated brain tumour classification using MRI images. The model processes a 224 × 224 grayscale MRI image through an initial convolution layer to extract basic visual features. Fused-MBConv blocks improve computational efficiency and capture intermediate representations, while an attention-enhanced Fused-MBConv block highlights important tumour region. In deeper layers, MBConv blocks with Squeeze-and-Excitation and channel attention refine feature channels and suppress irrelevant information, enabling the network to learn discriminative tumour characteristics effectively.

To improve tumour detection performance, the proposed framework integrates channel attention and spatial attention mechanisms within the MBConv blocks.

Channel Attention

Channel attention emphasizes the most informative feature channels by assigning adaptive weights. The channel attention process is defined as

$$M_c(F) = \sigma(W_2 \cdot ReLU(W_1 \cdot GAP(F))) \qquad (3)$$

where F represents the feature map, GAP denotes Global Average Pooling, W_1, W_2 are learnable weight matrices, σ represents the sigmoid function, The refined feature map is obtained as

$$F' = M_c(F) \otimes F \qquad (4)$$

where $\otimes$ represents element-wise multiplication.

Spatial Attention

Spatial attention identifies important regions within the feature maps and highlights tumour-related areas.

$$M_s(F) = \sigma\big(Conv_{7\times7}([AvgPool(F); MaxPool(F)])\big) \qquad (5)$$

where $AvgPool$and $MaxPool$ represent average and max pooling operations, $Conv_{7\times7}$ denotes convolution with a 7×7 kernel. The spatially refined feature map is computed as

$$F'' = M_s(F') \otimes F' \qquad (6)$$

By combining both channel and spatial attention, the model learns to emphasize tumour regions while suppressing irrelevant background information. After attention-enhanced feature extraction, the feature maps are passed through a GAP layer to convert them into a compact feature vector.

$$GAP(F) = \frac{1}{H\times W}\sum_{i=1}^{H}\sum_{j=1}^{W} F_{i,j} \qquad (7)$$

where H and W denote the spatial dimensions of the feature map. By the number of parameters gets reduced. The concatenated feature vector is then sent through a fully connected layer using ReLU activation function and then a Softmax classifier is used for categorizing the tumour. The Softmax function is represented as

$$P(y_i) = \frac{e^{z_i}}{\sum_{j=1}^{C} e^{z_j}} \qquad (8)$$

where z_i the output of the fully connected layer, C the number of tumour classes. Figure 2 shows the EfficientNetV2 model's design, which seeks excellent accuracy and computing efficiency. The model utilizes a 224×224 RGB image via convolution operation at the beginning to detect fundamental features. Features in the middle are obtained efficiently through Fused-MBConv, and deeper layers with SE in MBConv help identify relevant channel features. With progression in the network, the spatial size decreases while feature depth increases. Lastly, global average pooling, full-connected layer with SiLU, and Softmax layer contribute to the classification task. As Table 1 shows below, there are several differences between the initial architecture of EfficientNetV2 and the modified EffNetV2 model. Adaptations have been made to the input stem, fused-MBConvs, expansion ratios, and classification head to enable classification tasks using MRI for brain tumors.

RESULTS AND DISCUSSION

Brain tumours represent one of the most aggressive conditions that afflict both children and adults; 85–90% of primary central nervous system tumours constitute brain tumours. An estimated number of 11700 people develop brain tumours each year and the survival rate for a central nervous system tumour stands at 34% for men and 36% for women. Tumours are classified as benign, malignant, and pituitary. Proper treatment and planning for the life expectancy of patients requires a correct diagnosis and proper treatment plan [21]. MRI is considered the best method for detection and is performed by radiologists. Limited knowledge in some areas has led to delayed diagnoses, which is the reason why automation has become popular. Brain Tumour Classification (MRI). The processed data are employed during the training step using loss minimization. A validation stage provides an opportunity for hyperparameter selection and finally testing to evaluate the model. The effectiveness of the model is measured through various metrics including accuracy, precision, recall, and F1 score, guaranteeing efficient and generalized classification performance. Figure 3 represents images of brains from MRI data categorized into four classes including benign, malignant, pituitary tumor, and normal brain. Every row represents a unique category exhibiting differences in terms of anatomy, location, and intensity. Images of benign and meningiomas have clear mass areas, pituitary images concentrate on abnormalities of the sellar area, and normal images depict normal brain structures, making it possible to differentiate images by class visually.

Performance Evaluation Metrics

Accuracy

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \qquad (9)$$

Precision

$$Precision = \frac{TP}{TP+FP} \quad (10)$$

Recall (Sensitivity)

$$Recall = \frac{TP}{TP+FN} \quad (11)$$

F1-Score

$$\text{F1-Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (12)$$

Table 2 highlights the comparative performances of different versions of EfficientNetV2 models based on their evaluation through classification measures like accuracy, precision, recall, and F1-score. These include the basic EfficientNetV2 model, the version of EfficientNetV2 integrated with channel attention, the version of EfficientNetV2 integrated with spatial attention, and the proposed modification of EffNetV2 model. The performance of the basic EfficientNetV2 is 96.84% for accuracy, with precision, recall, and F1-scores of 93.73%, 93.69%, and 93.69%, respectively. Inclusion of attention improves the performance. The efficiency of EfficientNetV2 model integrated with channel attention yields 97.10% for accuracy, with precision, recall, and F1-scores of 94.20%, 94.19%, and 94.19%, respectively. The model of EfficientNetV2 with spatial attention shows improved performance, achieving 97.47% accuracy, with precision, recall, and F1-scores of 94.98%, 94.95%, and 94.95%, respectively. It can be concluded from the results that inclusion of both channel attention and spatial attention improves the learning capabilities of EfficientNetV2 model by enabling the model to focus on more relevant features and important tumour areas in MRI images.

EfficientNetV2 with spatial attention proves more effective than EfficientNetV2 and efficient channel attention, showing the usefulness of attention mechanism in improving the efficiency of the classification task. The newly developed modified EffNetV2 demonstrates higher performance on all evaluation metrics and gives 98.23% accuracy, 96.49% precision, 96.46% recall, and 96.47% F1 score. Architectural changes in combination with attention-based feature augmentation considerably improve the ability of the network to recognize features of brain tumors. The results of the classification process for the four classes are presented in Figure 5. There are 96, 94, 95, and 97 predicted instances belonging to each class, which are benign, malignant, pituitary, and normal, respectively. The number of misclassification is very low, with only 1–2 mistakes from one class to another, such as malignant classified as benign (2) and pituitary classified as normal (2). Comparison of the various brain tumor classification methods based on quantitative measures is illustrated in Figure 6. MobileViT gives 97.0% of accuracy and an F1 score of 96.0 whereas the VGG16-SVM algorithm delivers 97.8% of accuracy and an F1 score of 97.2. Federated learning with CNN produces 95.67% accuracy with extremely high precision value at 99.0%. The method of dilated SE-DenseNet gives a good measure at 96.5 F1 score. The Proposed EfficientNetV2 gives the highest measure of accuracy at 98.23%.

CONCLUSION

A Brain-EffNetV2 with enhanced attention capability was presented for the purpose of classifying brain tumors with MRI images and making the diagnosis process precise and automatic. Using MRI data for training together with the careful preprocessing process made it possible to obtain higher-quality data and increase the generalization capability of the model. With the inclusion of channel and spatial attention methods in the EfficientNetV2 architecture, distinguishing features of tumors were extracted in a more efficient way while reducing the effect of irrelevant regions in the image. Superior performance was shown in experiments conducted using several performance metrics, indicating the reliability and robustness of the model used. The model reduces human dependency, ensures consistency in the results, and offers a faster diagnosis compared to existing techniques. Such an innovation becomes extremely useful in those regions where trained radiologists cannot be reached easily. While the model performs quite well, further studies may focus on large-scale multi-institutional data sets, easier implementation for clinical applications, and explainable AI approaches.

Table1. Architectural Comparison Between EfficientNetV2 and Modified EffNetV2

Architectural Component	EfficientNetV2 (Base Architecture)	Modified EffNetV2 (Proposed Adaptation)	Purpose of Modification
Input Type	3-channel RGB images	1-channel (grayscale) or optimized MRI input	Adapts network to medical imaging data
Input Stem	Fixed kernel and stride	Tuned kernel size and stride	Preserves fine anatomical details
Early Feature Blocks	Limited Fused-MBConv blocks	Expanded use of Fused-MBConv blocks	Faster training and better early feature learning
Deep Feature Blocks	MBConv with SE blocks	MBConv with reduced expansion + SE	Controls model complexity and overfitting
Expansion Ratio	Fixed, stage-defined	Reduced or customized per stage	Balances representational power and efficiency
Squeeze-and-Excitation	Standard SE configuration	Lightweight SE (reduced channel ratio)	Prevents overfitting on small datasets
Depth Scaling	Strict compound scaling	Custom depth scaling	Improves generalization under limited data
Width Scaling	Compound scaling applied	Selective width adjustment	Enhances subtle tumour feature capture
Activation Function	SiLU (Swish)	SiLU or alternative (ReLU6 / Mish)	Improves convergence stability
Drop-Connect	Applied uniformly	Reduced or disabled	Stabilizes training on medical datasets
Classification Head	GAP + single FC layer	GAP + FC + Dropout	Improves class discrimination
Output Layer	Softmax (ImageNet classes)	Softmax (4 tumour classes)	Task-specific classification
Overall Architecture	General-purpose vision model	Medical imaging–optimized backbone	Domain adaptation without redesign

Table2. Performance Comparison of EfficientNetV2 Variants for MRI-Based Brain Tumour Classification

Performance Metrics	EfficientNetV2 (Base Architecture)	EfficientNet V2 + Channel Attention	EfficientNet V2 + Spatial Attention	Modified,EffNetV2 (Proposed Adaptation)
Accuracy	96.84	97.10	97.47	98.23
Precision	93.73	94.20	94.98	96.49
Recall	93.69	94.19	94.95	96.46
F1-Score	93.69	94.19	94.95	96.47

ABSTRACT

Slow-learning students often carry a quiet burden—falling behind in class, feeling different from their peers, and battling constant worry. Over time, this anxiety can dim their confidence and joy in learning. Grounding techniques, simple strategies that bring attention back to the present moment, offer a way to pause, breathe, and feel safe again. In occupational therapy, these small moments of calm can become stepping stones toward better focus, emotional balance, and active participation in school life. This study explores how grounding can ease anxiety for these students and help them feel comfortable in their learning journey. The study involved 30 children aged 6–12 years diagnosed with mild to severe anxiety. Participants were randomly divided into two groups: the experimental group (N=15) received grounding techniques, and the control group (N=15) underwent conventional occupational therapy. Both groups participated in 36 sessions over three months, each lasting 45 minutes. Anxiety was assessed using the Generalized Anxiety Disorder Scale -7(GAD-7) before and after the intervention. The GAD-7 includes 7 questions to evaluate anxiety levels from 0-4 (minimal anxiety) to 15-21 (Severe anxiety). Our findings reveal a high statistically significant difference in the post-test score between the experimental group and the control group of GAD-7 (p=0.000). The mean test score of the experimental group was 9.87 with a standard deviation of 3.292, while the mean post-test score of the control group was 14.47 with a standard deviation of 2.924. This suggests that the intervention received by the intervention group led to greater improvement in reducing anxiety compared to the control group. This study shows that grounding techniques can make a real difference in easing anxiety for slow-learning students. By helping them stay present and connected through simple sensory and physical exercises, these strategies reduced feelings of

restlessness, nervousness, and emotional strain. Students not only managed stress more effectively but also gained confidence in both learning and social settings. Grounding helped them feel calmer, safer, and more in control, fostering emotional stability and resilience. These results highlight the value of including grounding techniques as a gentle, nonmedical approach in educational and therapy plans—supporting the emotional well-being and active participation of slow-learning students

Keywords: Slow learning students, Anxiety, Grounding technique, occupational therapy,Generalized Anxiety Disorder-7 scale(GAD-7 Scale)

INTRODUCTION

Occupational Therapists can intervene in a variety of adverse situations. Life areas impacted by the disease such as daily tasks, sleep, work, play, socialization, education, and living. To emphasize the value of occupational therapy in improving the quality of life for those suffering from anxiety disorders [1]. Occupational therapists are essential members of our communities because they help patients participate in the important tasks of everyday life. Illness and injury are a step that interferes with an individual's capacity to live independently [2]. Anxiety has also been defined as a vague, uncomfortable feeling exacerbated by prolonged stress, and the presence of multiple stressors defines anxiety as an emotional condition characterized by fear, concern, and physical arousal. It is a state in which an individual worries, feels nervous, and becomes uneasy, sometimes of being menaced by an unspecified threat to one's personality [3,4]. When anxiety results in excessive physiological arousal, cognitive, emotional, and behavioral symptoms, along with subjective suffering and functional impairment, it is classified as a disorder. Children as young as two years old can be diagnosed with anxiety disorders, which are not limited to any specific gender, culture, or age group. Anxiety is characterized by subjective feelings of tension, apprehension, nervousness, and worry, all of which are associated with the arousal of the nervous system. A heightened level of anxiety can make it difficult for a person to maintain a normal life, leading to interruptions in daily activities and social interactions [5].

Symptoms of "overall anxiety" and "more specific overall" anxiety were present in 38% and 26% of slow learners, respectively. Globally, anxiety disorders rank among the most prevalent psychological disorders in students, and research has shown that they adversely impact their academic, social, and personal growth. Slow learners experience diverse cognitive challenges and often lag in the standard classroom because the pace and techniques of instruction do not align with their learning capabilities. They face academic challenges in reading, writing, and comprehending and performing mathematics; they exhibit deficits in executive function, weak working memory, and frequently have difficulties related to social skills [6]. When someone is experiencing dissociation or feeling overwhelmed by memories or strong emotions, grounding techniques help them refocus on the presentmoment. The feeling of leaving a movie theater serves as a useful metaphor. Whenthe individual dissociates or encounters a flashback, it resembles viewing amind movie; using grounding techniques, he or she may exit the movie theatre and enter the current setting and sunlight. The client's responsibility is not just to cling to moments from the past, but also to recognize that what he or she was going through is from a previous time [7]. Grounding is an effective method that can assist individuals with anxiety by re-establishing a connection with the present moment and anchoring themselves in reality [8].

METHODOLOGY

Research Design: A True experimental study design was employed to investigate the effectiveness of grounding techniques in reducing anxiety among slow learning students.

Sampling Technique: The study utilized a randomized sampling technique to select participants.

Sample size:A total of 30 subjects participated in this study. The participants were divided equally into two groups:
- **Experimental group:** 15 subjects underwent grounding technique interventions.
- **Control group:** 15 subjects received conventional occupational therapy.

Sample Setting: The study was conducted at St. Mary's Matriculation Higher Secondary School, Sriperambatur.

Selection Criteria:

Inclusion Criteria-

1. Age: Students aged 11-13 years.
2. Grade Level: Students in 6th to 8th standard.
3. Students with moderate to failing performance on the academic performance scale.
4. Anxiety Levels: Students with moderate to high levels of anxietyus(measured by a generalized anxiety scale-7-item scale).
5. Both male and female

Exclusion criteria

1. Students unwilling to participate in the study
2. Students with other co-morbidities(Other health issues)

Screening Tools Used: The Academic Performance Scale (APS), developed by Carson Birchmeier, Emily Grattan, Sarah Hornbacher, and Christopher McGregory (Saginaw Valley State University), was used to assess students' scholastic functioning. It consists of 8 items covering domains such as attention, classroom engagement, homework/assignment completion, study habits, and overall academic motivation

Scoring method:

Each item is rated on a 5-point Likert scale:
1 = Strongly Disagree | 2 = Disagree | 3 = Neutral | 4 = Agree | 5 = Strongly Agree

Total score range: 8 – 40
Interpretation:

Each item is rated on a 5-point Likert scale:
1 = Strongly Disagree | 2 = Disagree | 3 = Neutral | 4 = Agree | 5 = Strongly Agree

Total score range: 0– 40

Interpretation:

33-40(Excellent Performance)
25-32(Good Performance)
17-24(Moderate Performance)
9-16 (Poor Performance)
0-8(Failing Performance)

Reliability and Validity

- **Reliability:** Test–retest reliability over two weeks was r ≈ 0.84, supporting stability.
- **Validity:** Scale scores showed adequate internal consistency,2-week test-retest reliability, and satisfactory concurrent validity.

TOOLS USED

Generalized Anxiety Disorder-7 scale(GAD-7)

The Generalized Anxiety Disorder-7 (GAD-7) is a 7-item self-report questionnaire designed by Spitzer et al. (2006)[11]to screen for generalized anxiety disorder and measure its severity.

Scoring Method

Each item is rated on a 4-point scale:
0 = Not at all
1 = Several days
2 = More than half the days
3 = Nearly every day
Total score range: 0–21
scores:
0–4 → Minimal anxiety
5–9 → Mild anxiety
10–14 → Moderate anxiety
15–21 → Severe anxiety

Reliability and validity:

- **Reliability-**The GAD-7 demonstrates high reliability with Cronbach's alpha ≈ 0.89 and good test–retest reliability (ICC ≈ 0.83)
- **Convergent validity**: Strong correlations with other anxiety measures such as the Beck Anxiety Inventory (r ≈ 0.72) and the Penn State Worry Questionnaire (r ≈ 0.74).

Intervention Procedure:

The study was conducted over 12 weeks, with participants attending 30 sessions (3 sessions per week), each lasting 45 minutes. The intervention was structured as follows:
• Warm-up activities: 10 minutes.
• Program activities: 30 minutes (grounding technique for the experimental group and conventional therapy for the control group).
• Wind-up activities: 5 minutes.

Conventional Occupational Therapy for the Control Group

The therapy sessions focused on reducing anxiety among slow learning students, including activities such as:

Classroom-Based Interventions: Teachers and educational administrators have a critical role in tackling and lessening the worry among students in their schools. Students frequently see particular.The interpersonal and instructional methods of their teachers help lower Classroom anxiety. strategies like open book,support of a peer during class, working with a partner in the computer lab[13].

Family-based Cognitive Behavioral Therapy (FCBT): Family-based Cognitive Behavioral Therapy (FCBT) enhances treatment results for children. Involving parents in FCBT for children with anxiety-related school refusal was shown to significantly improve school attendance and adjustment, even if the child did not get direct therapy. Although they could not identify which age group profited the most, the authors hypothesized that younger children may gain more since they are more affected by their parents[13]**.**

Psycho education: Psycho educational interventions combine cognitive behavioral therapy, group support, and education to help patients and families understand the illness and its treatment, allowing them to work closely with professionals for better outcomes. Recent studies highlight their value across the life span, especially for children,

adolescents, and caregivers. Such interventions have been shown to improve mental health awareness and reduce anxiety levels, making them particularly relevant for slow-learning students struggling with anxiety[12].

Session Duration: 30– 45 minutes, 2– 3 times per week
Pre- and post-intervention assessments were conducted using the GAD-7 SCALE

Grounding technique for the Experimental group

Session 1-2	Introduction about myself and self-introduction about the students. Explain about grounding technique and get the concern form. Screening was done using the academic performance scale
Session 3-4	Assessed pretest using Generalized Anxiety Disorder-7 Scale(GAD-7)
Sessions 5–10	• Warm-Up: Breathing exercises, body scanning, gentle stretching • Active Phase: Introduction totheconcept of grounding, Basic 5-4-3-2-1sensory technique, Progressive musclerelaxation (PMR), Journaling sensations or emotional states • Wind-Down:Guidedimagery, group sharing
Session 11-15	• Warm-Up: Breathing with awareness, light yoga Active Phase: Deepening 5-sensegrounding (touch/texture focus),Sound and movement awareness, Mindful walking(barefoot if possible), Use of sensory objects(clay, sand, textured fabrics) • Wind-Down: Gratitude journaling, soft
Session 16-20	• Warm-Up: Emotioncheckin using emotion wheels • Active Phase:Naming emotions +grounding * Anchoring statements (“Iam safe…”), EFT tapping (Emotional Freedom Technique), Grounding throughstorytelling/personal narrative • Wind-Down: Reflection circles, breath-focusedmeditation
Session 21-25	• Warm-Up: Rhythmic clapping, joint rotations. • Active Phase: Grounding through dance (freestyle, tribal beats), Body percussion and grounding stomp routines, Yoga grounding poses(mountain, tree, child’s) * Walking meditation outdoors • Wind-Down: Journaling, cooling stretches
Session 26-30	• Warm-Up: Recalling positive memories. Active Phase: Grounding using affirmations, Thought-stopping + shifting exercises, Visualization of safe spaces, Nature grounding(rocks, leaves, natural textures) • Wind-Down: Deep breathing, cognitive reframing recap
Session 31-35	• Warm-Up: Breathing & gratitude affirmations • Active Phase: * Combiningall techniques intoapersonalized “GroundingToolkit”, Role-play stress scenarioswith grounding responses* Creating a groundingjournal or collage * Self-guided grounding scripts • Wind-Down: Final reflections, opengroupsharing, celebration
Session 36	• Assess post-test of GAD-7scale and get feedback about the past sessions from the student, and changes observed by the teacher and the parents

Result:

Table1: Statistical analysis of age and gender group between control and experimental group
A total of 30 participants took part in the study. In the control group, there were no female participants (0.0%), while the experimental group included 3(20.0%) female participants. Regarding age distribution across both the experimental and control groups, 8 participants were aged 11 years, 6 participants were aged 12 years, and 1 participant was aged 13 years.

Table 2: Statistical analysis between pre-test and post test scores in control group

In the above table, the p-value less than 0.05 and is significant at 5% level, and hence we can say that there is a significant difference of anxiety scores between pre- and post-tests in the control group. Also, the mean value of post-test scores is less than the mean value of pretest scores, and the difference is significant. Hence, we can conclude that conventional occupational therapy is significantly decreasing anxiety scores in the control group

Table 3: Statistical analysis of anxiety scores between pre- and post-tests in the experimental group

In the above table, the p-value is less than 0.01 and is highly significant at 1% level, and hence we can say that there is a highly significant difference in anxiety scores between pre- and post-tests in the experimental group. Also, the mean value of post-test scores is less than the mean value of pre-test scores, and the difference is highly significant. Hence, we can conclude that the"Grounding technique" is high significantly decreases anxiety scores in the experimental group.

Table 4: Statistical analysis between the experimental and control groups

In the above table, the p-value is less than 0.01 and is highly significant at 1% level and hence we can say that there is high significant difference of post-test level anxiety scores between control and experimental groups. Also, the mean value of the experimental group is lesser than the mean value of the control group and the difference is highly significant. Hence, we can conclude that the "Grounding technique" is high significantly decreasing anxiety score in the experimental group than then the conventional occupational therapy.

DISCUSSION

The study assessed the effectiveness of an intervention program in decreasing anxiety among slow-learning students, utilizing the Generalized Anxiety Disorder-7 (GAD-7) scale as the primary assessment tool. Participants were divided into control and experimental groups, and pre-test and post-test scores on the GAD-7 scale were analyzed. The statistical analysis of the control group's pre-test and post-test scores on the GAD-7 scale (Table 2) revealed significant improvement. The mean decreased from 15.93 to 14.47, with a p-value of 0.013, indicating a statistically significant difference at the 5% alpha level. Consequently, the alternate hypothesis, suggesting a significant difference between pre- and post-test scores of the control group, is accepted. Similarly, the findings of Elizabeth A. Hoge et al. (2017)[9]reported that mindfulness meditation is an effective technique for improving occupational functioning and health care utilization in individuals with anxiety.

The significant findings presented in Table 3, analyzing the experimental group's pre- and post-test scores on the GAD-7 scale, underscore the effectiveness of grounding techniques. The highly significant difference, as indicated by the p-value of 0.000, provides compelling evidence to reject the null hypothesis and accept the alternative hypothesis, suggesting a substantial improvement resulting from the intervention. The notable decrease in GAD-7 scores—from a mean of 15.80 (SD = 3.629) in the pre-test to 9.87 (SD = 3.292) in the post-test—demonstrates a strong statistical improvement in reducing anxiety. Similarly, the findings of Danang Riyanto et al. (2021)[10]indicated that grounding technique therapy was effective in reducing anxiety levels among students in the final stage of a master's nursing program. Our findings, as presented in Table 4, reveal a highly significant difference in post-test scores between the experimental group and the control group on the GAD-7 scale (p = 0.000). The mean post-test score of the experimental group was 9.87 (SD = 3.292), compared to 14.47 (SD = 2.924) for the control group. This suggests that the intervention received by the experimental group led to greater improvement in reducing anxiety compared to the control group.

Limitations

- This study was done on a small sample size
- The duration of this study was a short time
- The variability in individual cognitive and emotional profiles may have influenced the consistency of the result.

CONCLUSION

The findings highlight the significant impact of grounding techniques in reducing anxiety among slow learning students. The intervention proved to be practical and student-friendly, leading to observable reductions in restlessness, nervousness, and emotional distress. Participants demonstrated improved emotional regulation, attentional control, and confidence in academic and social settings. By directing attention to the present moment, grounding exercises reduced cognitive overload, enhanced emotional stability, and promoted a sense of safety and calm. These results provide strong evidence for incorporating grounding techniques as an effective, non-pharmacological strategy for anxiety management. The study underscores important implications for educators, therapists, and caregivers, emphasizing the value of integrating grounding techniques into individualized educational and therapeutic programs to foster resilience, well-being, and academic participation in slow learning students.

ABSTRACT

The infection caused by Mycobacterium tuberculosis (Mtb) still stands out as the most lethal infectious disease caused by a single infectious agent, with 10.8 million new infections and 1.25 million deaths being recorded in the year 2023 alone. In addition, MDR-TB and XDR-TB variants have been continually limiting the number of treatment alternatives that can be administered; hence, there is a need to develop new drug targets. The shikimate pathway involves the series of seven reactions which convert phosphoenolpyruvate (PEP) and erythrose-4-phosphate (E4P) to chorismate and is entirely missing in mammals and essential for the Mtb's survival. This article presents a comprehensive drug discovery pipeline involving all seven shikimate enzymes: DAH7PS, DHQS, DHQase, SDH, SK, EPSPS, and CS. The process starts with the computational screening of IMPPAT 2.0 phytochemical database (17,967 compounds from 4,010 Indian medicinal plants).Multi-criteria ADMET filtering (rules of Lipinski, Veber, Egan; SwissADME; ProTox 3.0) narrows the pool down to 40-100 molecules, which are then docked into resolved crystal structures using AutoDockVina. Binding affinity is verified with 100-200 ns molecular dynamics (MD) simulations in GROMACS, supplemented by MM-PBSA binding free energy calculation. Hits are further assessed in surrogate mycobacterial systems (*M. smegmatis* and *M. bovis* BCG) and cytotoxicity assays for THP-1 macrophages prior to the animal stage. Flavone-C-glycoside isoorientin demonstrated docking score of -9.4 kcal/mol towards shikimate kinase (PDB: 2IYQ) with stable MD binding (MM-PBSA: -8.2 kcal/mol), MIC_{90} towards M. smegmatis at 8.2 μM concentration and selectivity index greater than 12. This review also covers the approaches to lead formulations (encapsulation in

liposomes, PLGA nanoparticles), the notion of pan-shikimate inhibition and the crucial translation hurdles preventing the computational hits from entering the clinic.

Keywords: *Mycobacterium tuberculosis; shikimate pathway; virtual screening; molecular docking; ADMET; natural products; IMPPAT; molecular dynamics; MDR-TB; drug discovery*

INTRODUCTION

The discovery of *Mycobacterium tuberculosis* by Robert Koch back in 1882 was the starting point for arguably the longest ongoing battle in medicine [1]. Despite the use of BCG vaccine and multi-drug chemotherapy beginning in the 1950s, TB kills more than a million people every year. According to WHO Global Tuberculosis Report 2024, 10.8 million new TB cases and 1.25 million deaths were reported in 2023, and that puts Mtb back on track as the world's number-one single-pathogen killer [2,3]. India alone accounts for about 26% of the TB burden globally. Drug-resistant forms of bacteria worsen the situation. In 2023, 400,000 people had MDR-TB, resistance to rifampicin and isoniazid, the two key first-line drugs [4]. Less than half of those patients got proper treatment. XDR-TB, with addition of resistance to fluoroquinolones and other second-line drugs like bedaquiline or linezolid, leaves virtually no treatment possibilities but the few last resort drugs with toxic side effects [5]. Even novel BPaLM combination of four drugs (bedaquiline, pretomanid, linezolid, moxifloxacin) succeeds less than 70% of the time in clinical studies. There is hardly any new chemical entity coming down the pipe with an orthogonal mechanism of action. The importance of targeting such drug targets, which are metabolic processes in Mtb and absent in humans, cannot be overstated. An example of such a drug target is the shikimate pathway, which serves as the metabolic pathway of aromatic amino acid synthesis (phenylalanine, tyrosine, tryptophan), folate cofactors, menaquinones, and mycobactins. Mycobactins are small molecules, which serve as a chelator for scavenging iron from the human macrophages. Iron is an absolute requirement for growth of Mtb within the macrophages.

Shikimate pathway contains seven enzymes DAH7PS, DHQS, DHQase, SDH, SK, EPSPS, and CS encoded by different Mtb genes. Each enzyme has a solved crystal structure, and knockout of each gene leads to the death of Mtb [8]. However, shikimate pathway has attracted much less interest than the Mtb cell wall or RNA polymerase as a target of antimycobacterials due to difficult development of inhibitors of metabolism enzymes with complex active sites and also due to the plant and microbial biochemistry tradition [9]. Natural products constitute an excellent intermediate between what is presently known about structural biology and potential drug candidates. The immense Indian biodiversity is well documented through Ayurvedic/ethnopharmacological data and compiled into IMPPAT 2.0 database which contains 17,967 chemically characterized phytochemicals from 4,010 Indian medicinal plants [10]. Combining these chemically distinct libraries with those derived from marine sources along with ADMET predictors, docking using Auto Dock Vina and molecular dynamics using GROMACS allows us to build an efficient and repeatable virtual screening workflow. This review gives an account of this workflow, describes the representative data generated using shikimate kinase (MtSK) as the major drug target and talks about the translational issues that need to be tackled before moving ahead in this direction.

The Shikimate Pathway in Mycobacterium Tuberculosis

Shikimate pathway is present in bacteria, fungi, algae and higher plants, but entirely absent from mammals, who acquire the aromatic amino acids through dietary sources [11]. In Mtb, this pathway utilizes two intermediates of glycolysis and the pentose phosphate pathways, namely PEP and E4P, for the synthesis of chorismate by way of seven enzymes [6]. Seven genes code for the pathway enzymes in Mtb. Chemogenomic screens have demonstrated that deletion of a single one of these genes, including aroK coding for shikimate kinase, results in auxotrophic strains that grow inefficiently in conventional growth media and cannot infect macrophages [12,13]. The expression profiles of these genes have demonstrated their increased transcription in infected macrophages, implying that the shikimate

pathway is not only active, but absolutely necessary for the bacterium to thrive in the physiological conditions associated with pathogenesis of tuberculosis [8].

DAHP Synthase (DAH7PS)

The first step in this pathway is the condensation of PEP with E4P mediated by DAH7PS, in which a Mn^{2+} ion plays an essential role, forming 3-deoxy-D-arabino-heptulosonate-7-phosphate (DAHP). The enzyme of Mtb is a $(\beta/\alpha)_8$ TIM barrel folded into a tetrameric structure, which is different from the dimers and monomers of this enzyme in other bacteria [14]. The tetrameric form makes a potential allosteric site that reacts to pathway end-products, such as chorismate and prephenate. Phosphonates, based on the transition state structure of condensation reaction, have been proved to have IC_{50} of about 10 μM in other species.

Dehydroquinate Synthase (DHQS)

DHQS catalyzes the conversion of DAHP to 3-dehydroquinate (DHQ) via an exceptional 5-step mechanism which includes oxidation, dephosphorylation, ring cleavage, reduction, and intra-molecular aldol addition all taking place in a single active site without intermediates being released [15]. MtDHQS needs a tightly bound non-consumable NAD^+ co-factor and Co^{2+} ion for its catalytic activity. Bilobal dimeric structure forms an extensive active site cleft. While the NAD^+ binding pocket has been utilized as a potential target site for the development of inhibitors in other organisms, the inhibitors for MtDHQS have not yet been thoroughly characterized.

Dehydroquinate Dehydratase (DHQase)

The DHQase converts DHQ into 3-dehydroshikimate (DHS). Type II DHQases in bacteria utilize covalent Schiff-base catalysis involving an active site lysine; Type I catalysis occurs in fungi and plants [16]. The difference in mechanistic aspects is significant from the pharmaceutical point of view: inhibitors acting through the Type II Schiff-base approach cannot affect any human enzymes due to inherent selectivity. The MtbDHQase forms a unique dodecamer of twelve identical subunits in quaternary structure; this peculiarity among enzymes from the pathway makes it possible to design inhibitors for the subunit-subunit interface. Polyphenols epigallocatechin gallate (EGCG), found in green tea, act on Type II DHQases with IC_{50} about 30 μM, showing that plant compounds can reach the dodecameric active site.

Shikimate Dehydrogenase (SDH)

The SDH (aroE gene) converts DHS to shikimate using NADPH as the hydride donor. It is characterized by the presence of a Rossmann fold for the binding of NADPH along with the substrate-binding site. The enzymatic activity of SDH is carried out through the help of a Lys-Asp-Asn catalytic triad which is characteristic of SDR enzymes [17]. Several crystal structures of MtSDH with substrate and cofactor in the complex form are found in the Protein Data Bank. The binding pocket is rather open and can bind to competitive inhibitors during assays.

Shikimate Kinase (SK)

Shikimate kinase phosphorylates shikimate to shikimate 3-phosphate with one ATP, which is the only reaction in the whole process requiring ATP [18]. MtSK is the most well-characterised enzyme within the shikimate pathway, and acts as the principal target for the process outlined above in this review. Structural, inhibitor, and pharmacophore properties of MtSK are examined individually in Section 3 below.

EPSP Synthase (EPSPS)

The reaction of EPSPS leads to the formation of 5-enolpyruvylshikimate-3-phosphate (EPSP) from shikimate-3-phosphate and phosphoenolpyruvate with the liberation of inorganic phosphate [19]. The MtEPSPS protein forms a two-domain α/β structure and can undergo significant conformational rearrangement of the open to closed form upon substrate binding. Glyphosate, the herbicide, is a well-known inhibitor of EPSPS, and the structural determinants of its binding with MtEPSPS have been extensively studied. Unfortunately, glyphosate cannot be used as a potential anti-TB drug owing to its low membrane permeability and lack of specificity for the mycobacteria EPSPS compared to plant EPSPS.

Chorismate Synthase (CS)

CS completes the biosynthesis route through an anti-1,4 elimination of the 3-phosphate moiety along with C6 hydrogen from EPSP to give chorismate [20]. Mechanistically, this step is quite unique, since although it does not constitute a redox reaction, it needs reduced flavin mononucleotide (FMN) as an essential cofactor. There is no known human enzyme that carries out this chemistry, which makes MtCS an interesting selective target. Structural details on the interaction of MtCS with substrate analogs and FMN have been elucidated. Efforts towards developing bifunctional inhibitors which bind at both the EPSP binding pocket as well as FMN pocket have been made.

Shikimate Kinase (Mtsk): The Primary Target

Four factors distinguish the enzyme MtSK (aroK gene) among the seven pathway enzymes: it has the best understood structure (1.8 Å resolution, PDB: 2IYQ), it has the most biochemically characterized active site, it is the only enzyme which consumes ATP in the pathway (creating a pharmacophoric niche not covered by the other six enzymes), and there is an expanding dataset of inhibitors comprising both natural and synthetic compounds as well as allosterics. Mtsk belongs to the NMP kinase family and consists of a three-domain protein structure. The CORE domain is built from a five-stranded parallel β-sheet surrounded by α-helices and represents the scaffold of MtSK structure. The LID domain represents an α-helix domain folding over the ATP-binding site in the presence of nucleotide substrate with the purpose of isolation of γ-phosphate for its subsequent transfer. The shikimate-binding (SB) domain interacts directly with the substrate by making a salt bridge with arginines 57 and 136 and the carboxyl group of shikimate [18,22]. In the process of catalysis, movement of all three domains occurs cooperatively; specifically, the LID covers ATP while the SB domain encloses shikimate for their positioning to SN2 phosphoryl transfer reaction with participation of Mg^{2+} ion coordinated with Asp34 and β- and γ-phosphates of ATP [23]. The P-loop (10-16 residues, GxxxxGKS/T) binds the β-phosphate of ATP and defines nucleotide specificity.

Conformational plasticity of the LID domain poses both a problem and a unique approach to drug discovery. The rigid-receptor docking approach keeps the enzyme locked into a single conformational form; however, MtSK has two separate open and closed states, depending on the binding of the substrate and product, respectively, with considerable active site volume changes. The ensemble docking approach that uses multiple conformers generated via MD simulation partly resolves the problem at the expense of increased computational load. Moreover, the benzothiazole compounds have been proven to bind the allosteric pocket located at the LID-CORE interface and induce a new conformational form of the enzyme different from both the open and closed state with an IC_{50} value of 0.8 μM [24]. Manzamine alkaloids from marine sponges act as slow-binding and non-competitive inhibitors of MtSK, with Ki = 1.3 μM and MIC value of 2.0 μg/mL against Mtb H37Rv [23]. The kinetics of inhibition is characterised by a two-stage mechanism of induced fit interaction where fast weak binding is followed by a slower conformational change, leading to a stabilisation of the enzyme-inhibitor complex. This particular kinetic detail is of significant practical importance for inhibitor design since slow-binding inhibitors exhibit pharmacodynamic properties in vivo due to their long retention time in the active site. The computationally identified inhibitors of MtSK by means of phytochemicals are flavonoids (quercetin, luteolin, apigenin, and their derivatives), which form several hydrogen bonds with the residues Arg57 and Arg136 and stack interactions with aromatic residues at the ATP-binding site [25,26]. Terpenoids like ursolic acid and betulinic acid show predicted binding energy values between −8 to −10 kcal/mol, which are comparable or better compared to the known herbicide glyphosate. The flavone C-glycoside isoorientin shows docking energy of −9.4 kcal/mol and also shows stable MD binding energy of −8.2 kcal/mol with MM-PBSA as explained in Section 5.

Imppat 2.0 and Phytochemical Compound Libraries

It is estimated that natural products constitute around 25% of all approved drugs, but there are several examples in TB where natural products have led to the discovery of novel classes of drugs. Examples include streptomycin that originated from an actinomycete soil product; rifampicin originating from Amycolatopsisrifamycinica; and diarylquinoline framework used in bedaquiline, inspired from antimycobacterial natural products [27]. However, despite these examples, systematic computational screening of structured phytochemical databases against structurally characterised Mtb enzyme targets is relatively new. The IMPPAT 2.0, compiled by Vivek-Ananth et al., in

2023 is the largest database of Indian medicinal plants at present [10]. It includes 4,010 plants and 17,967 phytochemicals with validated 2D/3D structures, physicochemical data and precomputed ADMET predictions. Druglikeness calculations are done with five filters namely, Lipinski's Rule of Five, Veber rules, Egan rules, GSK 4/400 rule and Pfizer 3/75 rule. Of these 17,967 chemicals, 1,335 pass Lipinski's criteria for oral bioavailability. These 1,335 chemicals do not have close resemblance to any existing drug, hence are innovative.

The major phytochemical classes represented in IMPPAT 2.0, along with their relevance as pharmacophores to the shikimate pathway inhibition, are described below. Flavonoids, including flavones, flavonols, flavanones, isoflavones, and chalcones, provide multiple hydroxyl groups on planar aromatic ring systems, which allows hydrogen bonding to polar enzyme active sites and π-stacking interactions with purine cofactor [28]. It is known that quercetin, baicalein, and kaempferol could be docked to MtSK and predicted binding energies were estimated above −8 kcal/mol. Terpenoids such as monoterpenes, sesquiterpenes, diterpenes, and pentacyclic triterpenes (ursolic acid and oleanolic acid) provide hydrophobic scaffold suitable for the interaction with the amphipathic binding pockets of cofactor-dependent enzymes [29]. In addition, the extremely lipid-rich cell wall of mycobacteria can provide an advantage to permeate into cells for lipophilic terpenoid scaffold. Alkaloids are one of the most frequently used classes of compounds for the treatment of mycobacterial infections; berberine, emetine, and manzamines provide unique pharmacophores that can interact with the enzymes from shikimate pathway [30]. Phenolic acids and coumarins, which are structurally simpler compared to flavonoids, have established ADMET properties and previously proved inhibition of bacterial metabolic enzymes. Apart from the IMPPAT 2.0 library, marine compound libraries obtained from brown, red algae and cyanobacteria (available via MarinLit and other databases) provide chemotypes not seen in terrestrial plant chemistry. Marine organisms are especially abundant in halogenated terpenes, macrolides, and peptides, which have been found to be active against mycobacteria in phenotypic screening. Use of both terrestrial and marine libraries guarantees maximal chemical space diversity, which is essential while hitting several enzymes at once.

Phase I: In Silico Virtual Screening and Admet Filtration

Building the Compound Library

The process of virtual screening starts with proper database curation. Structures are downloaded in SMILES format from databases such as IMPPAT 2.0 (bioinfo.barc.res.in) and the marine compound databases. Prior to any filtering process, duplicate structures are removed based on canonical SMILES comparison, structures with undefined stereocenters or conflicting atom valences are removed, and structures containing heavy metals such as mercury, lead, arsenic, and cadmium or reactive toxicophores are eliminated. The database now contains around 15,000 – 18,000 organic structures.

Multi-Rule ADMET Filtration

The process includes four consecutive rules for filtering out compounds that have potential for oral absorption, delivery to the lungs, and do not harm the host in any way. The filters are used in SwissADME (swissadme.ch) using batch filtering of the complete list of compounds. Lipinski's Rule of Five (1997): MW≤500 Da; calculated LogP≤4.15; hydrogen bond donors≤5; hydrogen bond acceptors≤10 [31]. Molecules failing multiple criteria are rejected, but exceptions are made for natural products having active transport mechanisms. Veber's criteria: rotatable bonds≤10; and topological polar surface area (TPSA)≤140 Å² [32]. The two features independently predict intestinal absorption and membrane permeability and do not rely on lipophilicity. They are especially important for compounds that have to pass through mycobacterium's lipid-filled cell wall. Egan's criteria: weighted LogP≤5.88; TPSA≤132 Å², and select compounds highly predisposed to high passive membrane permeability [33]. Pharmacokinetic constraints by using SwissADME tool: predicted gastro-intestinal absorption – "High"; blood-brain barrier permeability – "Non-permeable," as central nervous system penetration is not required for anti-TB agents and is associated with safety risks. Application of four filters to the initial set of 17,500 compounds results in selection of 150-400 molecules (1-3% passage rate).

Toxicity Prediction Using ProTox 3.0

ProTox 3.0 (tox.charite.de) employs machine learning ensemble models, including random forests, support vector machines, and neural networks, trained on chemicals for which LD_{50} data are available [34]. Only chemicals classified as Class 4 or 5 (with predicted LD_{50} > 300 mg/kg; Table 1) progress. In addition, each chemical is filtered for predicted hepatotoxicity (SVM probability > 0.5 excludes chemicals from the study), Ames mutagenicity (any positive prediction excludes a chemical from the study), carcinogenicity (any positive prediction excludes a chemical from the study), and immunotoxicity. Following toxicity filtering, between 40 and 100 compounds generally persist to undergo molecular docking. It should be stressed that many complex natural products possess chemical groups such as catechol moieties or alpha-beta unsaturated carbonyl groups, which raise computational toxicity red flags due to their metabolism by the body in a very short time. The tendency to over-filter potential natural product hits is well-known problem of in silico toxicity software.

Phase II: Molecular Docking and Binding Analysis

Protein Structure Preparation

Crystal structures of all seven Mtb shikimate enzymes have been downloaded from the RCSB Protein Data Bank [35]. The preferred crystal structures are the ones resolved in complex with native substrates or mechanism-based inhibitors since these represent the active site geometry as found in the biological context. In the case of MtSK, PDB ID: 2IYQ has been selected, having been crystallized in complex with ADP and shikimate and representing an accurately resolved substrate-binding geometry at a resolution of 1.8 Å [21]. Each crystal structure has been prepared using AutoDockTools (MGLTools 1.5.6), specifically by removing all crystallographic water molecules; extraction of co-crystallized ligands to reveal the empty binding site; addition of missing hydrogen atoms and protonation of ionizable residues at pH 7.4; calculation and assignment of Gasteiger partial charges; and saving the protein in the PDBQT format. Each of the ligands in the filtered set has likewise been prepared using the same steps for the preparation in the PDBQT format, including the identification of rotatable bonds.

Grid Box Settings and Docking Parameters

A cubic search space is defined around the binding site inferred either from the co-crystallised ligand or, in its absence, the active site residues, which are identified through homology with characterised protein homologues. The search space grid for MtSK (PDB: 2IYQ) has its centre at X = 52.3, Y = 18.5, Z = 48.2 Å; box size = 20 × 20 × 20 Å, spacing = 0.375 Å, and encompasses completely the residues forming the P-loop (Gly10–Ser16), Asp34, and the shikimate co-ordination residues Arg57 and Arg136. AutoDockVina version 1.1.2 will be used with exhaustiveness = 32 (default is 8, which does not allow sufficient sampling), 10 poses reported per compound, and an energy range of 5.0 kcal/mol [36]. A ΔG (binding free energy) of −8.0 kcal/mol or better will qualify compounds for all six peripheral enzymes, while a threshold of −9.0 kcal/mol will be required for MtSK in keeping with the affinity of natural substrates. Cross-docking validation (redocking of the co-crystallised ligand and confirming that the generated pose matches with crystallographic pose within a maximum RMSD of 2.0 Å) will be carried out for each enzyme prior to screening.

Binding Interaction Analysis

Docking results are analyzed using BIOVIA Discovery Studio 2020 and PyMOL to generate high-quality figures. The type of intermolecular interaction is determined based on the following criteria: conventional hydrogen bond (the distance between donor and acceptor atom <3.2 Å and the angle >120°), carbon-hydrogen bond, electrostatic interaction (including π-cation and π-anion interactions; the distance between the aromatic ring and Lys or Arg<5.5 Å and Asp or Glu<5.5 Å, respectively), and hydrophobic interactions (including π-π stacking, two aromatic rings separated by the distance of 4.5-7.5 Å, and π-alkyl interactions) [37]. In MtSK, any contact with P-loop residues (Gly10-Ser16) and the Arg57/Arg136

Molecular Dynamics Simulation

The docking process gives us a static view of interaction between the drug and its target. In molecular dynamics (MD) simulations, we assess the stability of the docked structure when put in a physiological aqueous condition and

allowed to move freely at body temperature. Simulation is done in GROMACS 2021 [38] through the use of AMBER99SB-ILDN force field for protein and GAFF2 for each ligand with the help of AM1-BCC partial charge parameters through Amber Tools. Protein-ligand complex is placed in a cubic periodic box with explicit TIP3P water molecules with 0.15 M NaCl. Size of whole system is 35,000 atoms.

The simulation process involves three major stages. Energy minimisation is done through steepest descent method for 10,000 steps where maximum force comes down to less than 1000 kJ mol^{-1} nm^{-1}. Equilibration process has 100 ps NVT (volume constant, 300 K, velocity rescaling) and then 100 ps NPT (pressure constant, 300 K, 1 atm, Parrinello-Rahman).The simulation runs last for 100-200 ns with coordinates recorded at intervals of 10 ps. Four parameters are assessed based on the production runs: backbone Cα RMSD – a plateau below 2.0 Å within 50 ns indicates that the complex is stable; per residue RMSF – active site residues have an RMSF below 2 Å; radius of gyration – a constant value assures us that the protein doesn't unfold; and number of protein-ligand H-bonds with time – a constant number of at least 2 H-bonds indicates a stable interaction pattern. The binding free energy using MM-PBSA method [39] which is evaluated for the last 50 ns gives a quantitative assessment of the binding energy: below −7.5 kcal/mol means stable binding energy.

Phase III: In Vitro Cytotoxicity and Antimycobacterial Testing

Mammalian Cell Cytotoxicity

Prior to toxicity assay against bacteria, cytotoxic effects on human cells need to be determined in order to establish a therapeutic window. THP-1 cells (ATCC TIB-202) are induced to macrophages using 50 nM of phorbol-12-myristate-13-acetate (PMA) for 48 hours [40]. Induced THP-1 cells represent the intracellular conditions where Mtb is located. Vero cells (ATCC CCL-81) serve as the control for mammalian cytotoxicity. Both cell types are cultured in RPMI-1640 with 10% FBS at 37°C and 5 The MTT test measures mitochondrial succinate dehydrogenase enzyme activity, which is considered an index for viability of cells [41]. Cells are seeded into 96-well plates at a density of 10,000 cells/well and incubated overnight to allow adherence. Compounds to be tested are added in serial two-fold dilutions ranging from 1 to 100 μM. The vehicle control wells contain up to 0.1% (v/v) DMSO whereas positive controls are treated with 1% Triton X-100. Formazan crystals are formed after 48–72 hours of incubation upon addition of 20 μL of MTT reagent (5 mg/mL). After incubating further for four hours, 100 μL DMSO is added to dissolve the crystals, and absorbance is measured at 570 nm. Percentage viability is calculated relative to vehicle controls and a sigmoidal dose-response curve is generated to determine the CC_{50} value.

Surrogate Mycobacterial Testing

Virulent Mtb H37Rv should be maintained in Biosafety Level 3 (BSL-3) facility. There are two nonpathogenic surrogates available for screening of compounds in lower level of biocontainment prior to use of BSL-3 facilities. *Mycobacterium smegmatis* mc^2155 (ATCC 700084) is fast-growing and non-pathogenic mycobacterium with waxy cell wall similar enough to that of Mtb and therefore suitable for testing permeability [42]. The cultures are grown in Middlebrook 7H9 medium (0.5% glycerol, 0.05% Tween-80, 37°C) and then diluted to OD_{600} = 0.05. MIC_{90} is defined using broth microdilution method: serial two-fold dilutions (0.39–100 μM) are used together with 10^5 CFU and incubated for 72 hours. Counts of colonies on Middlebrook 7H10 agar plates with OADC enrichment after 3-5 days are used to prove bactericidal effect (at least 3 $\log_{10}$ CFU reduction). M. bovis BCG (ATCC 35734) is attenuated strain used in TB vaccines, grows in non-BSL- The Selectivity Index (SI) is defined by the formula: SI = CC_{50} (human cells) / MIC_{90} (mycobacteria). An SI ≥50 implies that the compound is 50 times more toxic towards the bacteria compared to human cells, which marks the acceptable level of toxicity needed before advancing to in vivo experiments. The compound iso-orientin had a MIC_{90} value of 8.2 μM towards *M. smegmatis* and a CC_{50} value greater than 100 μM towards THP-1 cells; thus, an SI greater than 12 was observed.

PHASE IV: In Vivo Evaluation and Biosafety

Ethical and Regulatory Approvals

All animal studies need approval in writing from the IAEC under the Prevention of Cruelty to Animals Act, 1960 (India). The protocol that is submitted should include details about the species of animals and group size based on

statistical calculation, methods of infection and dosing, schedule of clinical observations, humane endpoint and the mode of euthanasia selected. It generally takes four to six weeks.

Animal Infection Model and Dosing

BALB/c mice are the traditional in vivo TB infection model; they are cheap, well-known immunologically, and develop progressive granulomatous lung infection in 2–4 weeks after aerosol infection. Hartley guinea pigs are used when a similar-to-human granuloma development is needed for histopathological comparison [43]. Aerosol infection using the Madison chamber (Glas-Col) at approximately 10^5 CFU/mL for 20–30 minutes provides uniform infection dose simulating natural route of transmission. Two to four weeks after infection, the animals are randomly assigned into treatment and control groups. Compounds under evaluation are dosed via oral gavage at 10–50 mg/kg per day one to two times for 4–8 weeks according to the compound PK half-life evaluated in previous single-dose experiment [44].

Endpoint Measurements

At week 4 during treatment, some animals are euthanized, their lungs and spleens are homogenized, and the homogenate is plated onto Middle brook 7H10 plus OADC agar. A 2 $\log_{10}$ CFU reduction in lung tissues compared to non-treated control animals is regarded as an efficacy endpoint. For histopathological examination, lungs are fixed in 10% neutral formalin, embedded in paraffin, sectioned at 5 μm, and stained with Haematoxylin and Eosin. The degree of granuloma formation is assessed on a 0 to 4 point scale (0 – no lesion; 4 – advanced disease with cavities) [45]. Oral acute toxicity test is conducted according to OECD Test Guideline 423 [46], where three mice get a single dose of 2000 mg/kg orally, and are monitored for 14 days. No animal deaths result in LD_{50} > 2000 mg/kg. Plasma pharmacokinetics are established after a single 50 mg/kg oral administration of the substance, followed by sampling of blood and tissues at 0.5, 1, 2, 4, 8, and 24 hours; compound levels are analyzed via LC-MS/MS [47].

Translational Challenges and Formulation Strategies

The In Vitro–In Vivo Disconnect

The major cause of failure of computationally screened phytochemical hits is molecular liability as opposed to target recognition failure. Many flavonoid glycosides and polyphenolics with good docking profiles tend to have molecular weight >500 Da, multiple H-bond acceptors, high TPSA values, and poor aqueous solubility, thus leading to reduced bioavailability [48]. In the case of quercetin, it is quickly converted by glucuronidation in the intestinal wall and first pass effect in the liver such that the concentration achieved does not get close to the in vitro IC_{50} for MtSK. For terpenoids and alkaloids, there are similar problems of being cleared in the cytochrome P450 3A4 pathway before reaching the lungs. Another critical difficulty lies in the highly impermeable nature of the cell wall of the mycobacteria. The covalent peptidoglycan-arabinogalactan-mycolic acid layer that contains the highly hydrophobic outer layer of C70-C90 mycolic acids constitutes one of the most difficult permeability barriers encountered in nature [49]. A molecule that might exhibit strong inhibition of the shikimate enzyme in isolation in a biochemical assay may not attain sufficiently high intracellular concentrations to exhibit biological activity. The mycobacterial cell wall is also responsible for conferring resistance to many antibiotics on the Mtb. Lastly, the computational screening studies published in the literature in this area vary widely in quality. A great many publications have proposed potential hits on the basis of AutoDockVina binding energy scores without MD proof, without comparison to a crystallo graphically proven positive control, without adequate protein preparation, and without any subsequent experimentation [50]. There is no agreement at present regarding what value for ΔG would be considered a good hit, what proof of MD binding stability would be sufficient, or even what kind of negative result would be appropriate.

Liposomal Encapsulation

Liposomes are spherical vesicles composed of phospholipid bilayers, which contain hydrophobic drugs within their bilayers and hydrophilic drugs within their aqueous core. In pulmonary TB, liposomes have pharmacological superiority because lung macrophages actively engulf liposomes – ensuring that drug is delivered precisely to the specific intracellular milieu in which Mtb resides [51]. In addition, the phospholipid layer reduces the first-pass effect via the CYP450 pathway in comparison to free drugs, leading to enhanced bioavailability. The preparation of

liposomes involves dissolution of the drug in ethanol, followed by mixing with egg phosphatidylcholine in a 1:5 drug-to-lipid molar ratio; formation of a lipid film via rotary evaporation, hydration with PBS, and size reduction by extrusion using 200-nm polycarbonate filters. The resulting product is assessed for its particle size via dynamic light scattering, encapsulation efficiency via HPLC, and stability over three months under 4°C.

Polymeric Nanoparticle Formulation

PLGA nanoparticles are biodegradable, FDA approved drug delivery systems where both size (50-500nm, depending on the polymer concentration and conditions used) and drug release rate (ranging from hours to weeks and controlled by lactic/glycolic acid ratios) can be individually optimized [52]. The particles are prepared using the double emulsion/solvent evaporation method or nanoprecipitation and evaluated for encapsulation efficiency and drug release profile in PBS or synthetic lung fluid at 37°C. Mannose modification on the surface ensures drug delivery through interaction with the mannose receptor on the macrophages. In addition, liposomal and PLGA systems overcome oral bioavailability issue by using inhalation or intravenous administration to the lungs.

Structure-Activity Relationship Guided Optimisation

Natural product hits do not constitute optimum lead drug molecules. Interaction maps from molecular docking show the functional groups involved in interactions with the target and those that protrude into the solvent environment and are pharmacokinetically unnecessary. These latter functional groups may be modified without interfering with binding; hydroxylation or addition of a carboxylic acid group enhances water solubility; replacement of unstable functional groups decreases clearance; removal of non-interacting ring systems reduces molecular size. Resynthesized analogues undergo docking and biological tests to construct a structure activity relationship (SAR). The pharmacophore from the active natural product serves as the basis for designing simpler drug-like synthetic analogues. This semi-synthesis approach, characterized traditionally by the transformation of artemisinin into artesunate for the treatment of malaria, offers promise for producing molecules with both natural product target interaction properties and drug-like pharmacokinetics [53].

Future Directions: Pan-Shikimate Inhibition and Ai-Driven Discovery

What makes the shikimate pathway as a drug target highly strategically distinct lies in the possibility of pan-shikimate pathway inhibition, which refers to finding inhibitors of two or more enzymes of the shikimate pathway. The fact that the enzymes involved in the pathway share shikimate as their common substrate/product pair (i.e., SDH produces shikimate and SK uses it up) suggests that an inhibitor molecule having a similar structure to shikimate could be used effectively to inhibit several active sites [54]. If an inhibitor capable of blocking MtSK and MtEPSPS at the same time were to be found, Mtb would need to develop resistive mutations on two separate gene loci to avoid being inhibited – a much more genetically difficult task than developing one such mutation. Computation-based pan-shikimate pathway screening entails dockings of the filtered phytochemical database against the seven enzymes simultaneously and compounds with high multi-target binding scores instead of binding affinity to individual enzymes will be ranked higher. Compounds that perform well in multiple targets will be considered for experimental verification using isobologram analysis to verify synergy and multiple target inhibition in live bacteria [55].

Artificial intelligence and machine learning are starting to revolutionize the process of natural product-based drug discovery at an early stage. Graph neural networks (GNNs) are able to predict binding affinities of ligands and proteins with MM-GBSA precision, making the screening of all 17,967 molecules in the IMPPAT 2.0 library against all seven shikimate enzymes a matter of hours, not weeks [56]. Generative methods such as variational autoencoders and diffusion-based molecular generation models can generate new structural analogs with improved pharmacological properties of the top hits, thus automating one cycle of lead optimization. Of course, this approach does not eliminate the need for biological experiments; it just speeds up their preparation. If one looks down the road towards the translation process, one can see that the leads derived from phyto compounds would not be used as drugs themselves, but rather as a source of ideas for synthetic chemistry. For instance, the active components of pharmacophore, which were derived from a flavonoid inhibitor of MtSK, could be incorporated in a smaller

molecule structure that would be better absorbed when taken orally and would still engage the biological target. PK/PD modelling, in combination with the analysis of patent landscape carried out at the early stage of the program, would increase the efficiency of the whole process.

CONCLUSIONS

Shikimate pathway of *Mycobacterium tuberculosis* is arguably the most robust and structurally accessible drug target axis in the anti-TB drug discovery space. All seven enzymes of the shikimate pathway are individually essential, structurally resolved, biochemically characterized and absolutely not expressed in the human host. However, it is the least experimentally investigated pathway compared to the Mtb cell wall or RNA polymerase. The recently constructed IMPPAT 2.0 database containing 17,967 structurally diverse phytochemicals derived from Indian medicinal plants systematically annotated for ADMET properties offers a compound library to fill this gap. The proposed pipeline consisting of ADMET filtration, AutoDockVina docking, GROMACS molecular dynamics, surrogate testing using *M. smegmatis* and BCG models, THP-1 cytotoxicity analysis and staged in vivo evaluation is reproducible, scalable and can be executed by an academic laboratory in the absence of specialized infrastructure at most stages. The isoorientin is shown as an example of the validated hit (MtSK $\Delta G = -9.4$ kcal/mol; MM-PBSA = −8.2 kcal/mol; *M. smegmatis* $MIC_{90} = 8.2$ μM; SI >12). What is required at this stage is not further computational screening rounds with increasing length of hit lists but careful refinement of the best leads via experimental validation starting from IC_{50} of the enzyme activity, followed by MIC in vitro and efficacy in vivo. The pan-shikimate inhibition, AI-assisted screening, and semi-synthesis driven by SAR are the three most promising routes that can be employed to move natural product-based inhibitors of the shikimate pathway to become clinical candidates for MDR-TB.

Table 1: ProTox 3.0 toxicity classification framework used for compound filtering

Class	Predicted LD_{50} (mg/kg)	Interpretation
1	< 5	Highly toxic — exclude
2	5–50	Toxic — exclude
3	50–300	Moderately toxic — exclude
4	300–2000	Harmful — borderline; include with caution
5	2000–20000	Slightly harmful — include
6	> 20000	Negligible toxicity — include

Only compounds classified as Class 4 or above (LD_{50} >300 mg/kg) advance in the pipeline.

Table 2: Protein Data Bank entries and structural features of the seven Mtb shikimate pathway enzymes

Enzyme	Gene	PDB Entry	Structural Features
DAH7PS	aroG/F	2B7O / 1QR7	TIM barrel, tetramer; allosteric pocket
DHQS	aroB	2YBQ / 1DQS	Bilobal dimer; NAD^+ tightly bound
DHQase	aroD	2XB8 / 1DHQ	Dodecamer (Type II); Schiff-base Lys

SDH	aroE	2NPX / 1SDH	Rossmann fold; NADPH cofactor
SK	aroK	2IYQ	NMP kinase; CORE/LID/SB domains
EPSPS	aroA	2BJB / 1G3R	Two-domain α/β; glyphosate site
CS	aroC	1QXO / 1CSM	FMN-dependent homodimer

PDB = Protein Data Bank; TIM = triosephosphate isomerase; NMP = nucleoside monophosphate; FMN = flavin mononucleotide.

Table 3: Representative natural product and synthetic inhibitors of MtSK and related shikimate pathway enzymes

Compound	Class	IC_{50} / Ki / ΔG	MIC (H37Rv)	Inhibition Type	Reference
Manzamine A	Marine alkaloid	1.3 μM (Ki)	2.0 μg/mL	Slow-binding noncompetitive	Simithy et al., 2018
Benzothiazole derivative	Heterocyclic	0.8 μM (IC_{50})	ND	Allosteric (LID domain)	Mehra et al., 2016
Alpha-linolenic acid	Fatty acid	~50 μM (MtSK)	ND	Competitive (shikimate site)	Masoko et al., 2016
Isoorientin	C-glycoside flavone	9.4 kcal/mol (ΔG)	ND	Predicted (P-loop, Arg57)	Present study
Narirutin	Flavanone glycoside	In silico hit	ND	Predicted competitive	Sahu et al., 2020
EGCG	Polyphenol	~30 μM (DHQase)	ND	Type IIDHQ aseinhibitor	Reviewed herein

ND = not determined; ΔG = AutoDockVina binding free energy; MIC = minimum inhibitory concentration; EGCG = epigallocatechin gallate.

Table 4: AutoDockVina binding affinities (ΔG, kcal/mol) of representative natural product hits against all seven shikimate enzymes. Values meeting advancement thresholds are in bold.

Compound	DAH7PS	DHQS	DHQase	SDH	SK (2IYQ)	EPSPS	CS
Isoorientin	−7.4	−6.8	−7.1	−7.6	−9.4*	−7.2	−6.5
Orobanchol	-7.1	-7.6	-6.8	-8.9	-7.2	-9.1	-6.7
Stigol	-7.7	-8.1	-7.4	-6.3	-8.8	-.8.7	-8.3

* Meets tightened MtSK threshold of −9.0 kcal/mol. TBD = to be determined upon completion of screening cascade.

ABSTRACT

Fog-enabled healthcare monitoring generates a continuous stream of patient-related tasks near IoT devices, where some requests are routine updates while others represent emergency alerts that demand immediate processing. Sending every task to a distant cloud can introduce unnecessary latency and congestion, which may delay critical decisions and reduce service reliability during peak arrivals. To address this challenge, this paper presents PBTA-S, a priority-based task allocation and scheduling mechanism for fog computing that improves responsiveness through multi-level fog node categorization. Incoming monitoring tasks are first classified into three urgency groups (critical, medium, and routine start/end) and then mapped to three fog resource tiers that reflect different processing capabilities and response roles. Each tier maintains an independent priority queue, and tasks are executed using a scheduling key that favors urgency and timeliness while maintaining fair ordering within the same class. When a preferred fog tier becomes overloaded, PBTA-S activates a controlled spillover strategy that shifts tasks to the nearest suitable tier based on predicted waiting time, preventing urgent workloads from being trapped in long queues. Simulation-driven evaluation under fog computing assumptions demonstrates that the proposed mechanism achieves faster service for critical tasks by reducing waiting and response time, while also lowering SLA/deadline violations under high-load conditions. Overall, PBTA-S shows that combining priority-aware allocation, tiered fog resource pooling, queue-based scheduling, and overload-aware spillover offers a practical and effective approach for mixed-criticality healthcare workloads in fog environments.

Keywords: Fog computing, IoT healthcare, Priority scheduling, Resource allocation, Latency, SLA violations, Edge computing

INTRODUCTION

The rapid adoption of IoT-based healthcare monitoring has enabled continuous tracking of patient conditions through wearable sensors and smart medical devices. These systems generate a steady flow of data and service requests such as vital-sign updates, medication reminders, trend analysis, and emergency alerts [1]. However, not all tasks produced in healthcare environments carry the same urgency. A sudden drop in oxygen saturation, abnormal heart rate, or fall detection event requires immediate processing and response, whereas routine monitoring updates can tolerate minor delays [2][3]. In such mixed-criticality environments, the ability to process urgent tasks quickly becomes essential to support timely clinical intervention and to maintain the reliability of health monitoring services [4]. Although cloud platforms offer high storage and computational scalability, relying only on centralized cloud processing is often unsuitable for latency-sensitive healthcare workloads. When all tasks are forwarded to the cloud, the system may experience increased communication delay, bandwidth overhead, and service disruption during network congestion or burst traffic conditions [5]. Fog computing addresses this limitation by bringing computation closer to where the data is produced, enabling faster decisions at the network edge. Yet, fog environments introduce their own challenges because fog nodes are distributed, heterogeneous, and resource-constrained when compared to centralized datacenters [6]. This makes task scheduling and resource allocation a critical concern, especially when urgent healthcare tasks compete with routine requests. Therefore, there is a strong need for a fog-oriented scheduling mechanism that can prioritize critical workloads, utilize fog resources efficiently, and reduce waiting time and SLA violations under varying load conditions [7].

To address these challenges, this paper proposes PBTA-S, a Priority-Based Task Allocation and Scheduling mechanism designed for fog computing in IoT healthcare environments. The proposed approach first evaluates each incoming healthcare task based on its urgency and assigns it to one of three priority classes, ensuring that emergency-like requests are never treated the same as routine monitoring updates. Next, fog resources are organized into multi-level fog node categories that represent different processing strengths and operational roles, and each category maintains a dedicated priority queue for structured task handling. PBTA-S then schedules tasks using a queue-driven allocation strategy that balances urgency and timeliness, while continuously tracking waiting time to avoid prolonged delays. When a preferred fog tier becomes saturated, an overload-aware spillover policy shifts tasks to the nearest suitable fog tier based on waiting-time thresholds, ensuring stable service continuity during traffic bursts. Through this design, PBTA-S improves fog-level responsiveness, reduces overall processing delay for critical tasks, and strengthens SLA adherence for mixed-priority healthcare workloads at the edge.

The key contributions of this paper are as follows:

- Fog-based priority classification for healthcare tasks: A structured three-level priority model is introduced to differentiate critical, moderate, and routine healthcare requests, enabling urgency-aware decision making at the fog layer.
- Multi-level fog node categorization (resource-tiering): Fog nodes are grouped into capability-aware categories so that high-priority tasks are directed toward suitable fog resources rather than competing randomly across heterogeneous nodes.
- Queue-driven scheduling mechanism for mixed-critical workloads: Independent queues are maintained for each fog tier, ensuring systematic ordering and improved service discipline, especially during continuous task arrivals.
- Overload-aware spillover strategy for stable fog operation: A waiting-time threshold policy triggers-controlled spillover between fog tiers, preventing critical tasks from being trapped in long queues when preferred nodes are overloaded.
- Improved fog performance in delay-sensitive monitoring scenarios: The proposed PBTA-S approach enhances response time for urgent tasks and reduces SLA/deadline violations under high-load conditions, demonstrating suitability for real-time healthcare monitoring at the edge.

Related Work

Healthcare monitoring workloads typically involve heterogeneous tasks with different urgency levels, where delays in processing critical alerts can degrade response quality. To address this, Elshahed et al. [8] proposed a fog-computing–based healthcare monitoring framework that aims to support real-time patient notification with low latency. It collects vital signs such as body temperature, heart rate, and blood pressure using wearable sensors and processes the data closer to the patient through a fog gateway layer, instead of relying only on distant cloud servers. The system performs local filtering and analysis and triggers instant alerts to doctors/caregivers when abnormal readings cross threshold limits, while also supporting medication or diet reminders. Machine learning is used to assist decision-making for identifying critical conditions, and the cloud layer is mainly used for long-term storage and future analysis. The authors also emphasize handling healthcare constraints such as network failures via temporary local storage and propose security measures like encryption/watermarking along with compression for efficient cloud storage. Overall, the work highlights how fog computing improves QoS in healthcare by reducing delay and enabling timely intervention in emergency situations.

A closely related direction is to explicitly classify healthcare tasks by importance and align them with resource categories. Aladwaniet al. [9] proposed a fog-computing scheduling approach where IoT healthcare tasks are first classified into multiple importance classes based on patient status, and then assigned using a strategy that also considers VM categorization. This is particularly relevant because it moves beyond pure timing objectives to incorporate task criticality into placement decisions in a fog setting. This method is conceptually aligned with our work because it supports the idea that task classes should be mapped to VM classes, which naturally fits multi-level VM categorization. However, many studies still leave room for a more explicit end-to-end pipeline that separates (i) classification, (ii) category-level allocation, (iii) queue-level scheduling, and (iv) overload spillover policies as clearly defined mechanism components.

Healthcare monitoring is also characterized by dynamic context changes, especially in IoT scenarios where patients or devices can move across coverage zones. Abdelmoneem et al. [10]studied healthcare task scheduling across cloud and fog while considering mobility, proposing policies that aim to distribute tasks dynamically between fog and cloud nodes and reduce missed tasks under movement. These results reinforce that real deployments benefit from mechanisms that (a) remain responsive under changing loads and (b) adapt their allocation decisions when preferred resources are not immediately available. Such observations provide strong support for introducing overload-aware spillover rules (from a preferred category to an adjacent category) in scheduling mechanisms designed for mixed-criticality healthcare tasks.

Some scheduling research derives task priority from multiple criteria rather than a single indicator, typically using decision-making techniques. Ghafari and Mansouri[11] proposed a fog scheduling approach where Analytic Hierarchy Process (AHP) is used to determine task priority as part of a broader optimization method, targeting improved energy/time/cost behavior. Similarly, Hosseini et al. [12]used a fuzzy-AHP–assisted approach (PQFAHP) to manage cost–latency trade-offs in mobile fog computing, emphasizing that practical schedulers often need to handle multiple objectives and heterogeneous tasks with different priorities. El-Natat et al. [13] proposed a deadline-aware fog resource allocation approach for IoT healthcare monitoring, motivated by the need to handle time-sensitive medical workloads with low latency and fewer delays in comparison to cloud-only processing. Their work introduces a Task Classification algorithm based on Deadline and Criticality (TCDC), which explicitly prioritizes critical healthcare tasks first while also respecting each task's deadline constraints for real-time responsiveness. The authors evaluate TCDC in a fog environment and report improvements in key QoS indicators such as makespan and resource utilization, showing notable overall performance gains over baseline methods. The study also reinforces that deadline handling is a dominant QoS factor in fog-based healthcare scheduling, since many monitoring tasks must be completed within strict timing bounds to avoid unsafe delays. Overall, this work supports the view that combining criticality-aware prioritization with deadline-driven scheduling is essential for fog healthcare systems that must deliver fast and reliable responses under dynamic IoT workloads.

Sharif et al. [14] proposed a priority-based task scheduling and resource allocation (PTS-RA) mechanism for healthcare monitoring in a mobile edge computing (MEC) setting, where tasks are assigned priorities based on emergency levels derived from wearable-device data. Their method jointly decides whether each task should be processed locally (hospital workstations) or offloaded to the cloud, aiming to reduce overall processing time and bandwidth cost while ensuring emergency tasks run first. They evaluate the approach against existing methods using metrics such as average latency, execution time, network usage, CPU utilization, and energy consumption, reporting improved handling of latency-sensitive tasks. This work supports the importance of priority-aware scheduling in healthcare environments; however, it primarily focuses on edge–cloud offloading decisions rather than structuring cloud execution resources into multi-level VM categories based on expertise. Sirjaniet al. [15] proposed a deadline-aware fog scheduling framework for IoT applications where timely responses are critical. Their approach (RIGEO) dynamically classifies fog nodes into low-traffic and high-traffic groups based on observed network conditions, then applies different scheduling strategies to match deadline urgency: low-deadline tasks are scheduled on low-traffic nodes using an Improved Golden Eagle Optimization (IGEO) method (a discretized meta-heuristic enhanced with genetic operators), while high-deadline tasks on high-traffic nodes are handled using reinforcement learning (RL) for robust decision-making under congestion. The authors report that this hybrid design improves key QoS outcomes, including response time, deadline violation behavior, and energy consumption, compared with several existing methods. In the context of PBTA-S, this study is relevant because it demonstrates how resource categorization plus urgency-aware scheduling can improve timeliness under heterogeneous and dynamic loads, although its categorization is traffic/deadline-driven rather than expertise-tier VM pools.

Choppara and Lokesh [16]proposed a fog-computing scheduling framework for time-sensitive healthcare scenarios where sending all data to the cloud introduces avoidable latency. Their key idea is to use deep reinforcement learning (DRL) to learn dynamic task allocation decisions across nearby fog nodes so that urgent workloads are processed closer to where IoT health data is generated. They validate the approach using SimPy-based simulations that emulate multiple healthcare settings (e.g., continuous monitoring and emergency response), and show that the learned policy adapts to changing system states and resource demand. Reported outcomes indicate noticeable gains over traditional scheduling: up to 30% reduction in makespan / completion time, about 40% reduction in operational latency, and around 25% improvement in fault tolerance, highlighting the suitability of DRL for real-time fog-assisted healthcare processing. The study also positions the same DRL-based scheduler as transferable to other real-time domains, suggesting broader usefulness beyond healthcare.

Several studies have explored task scheduling and resource allocation in fog computing to support latency-sensitive IoT applications such as healthcare monitoring, smart cities, and industrial automation. In general, existing fog scheduling methods aim to reduce execution delay by placing computation closer to the data source, while also balancing workload across distributed fog nodes. Common approaches include heuristic-based scheduling, load-aware allocation, deadline-based processing, and energy-efficient placement strategies. However, many of these solutions treat incoming tasks in a mostly uniform manner or provide limited support for mixed-priority scenarios where emergency requests must be handled ahead of routine monitoring tasks. In healthcare contexts, this limitation can lead to avoidable delays because critical events may still experience long waiting times during burst traffic or fog node contention. Moreover, fog environments are naturally heterogeneous, and a scheduling policy that ignores capability variation across fog nodes may cause inefficient resource usage and SLA violations. These gaps highlight the need for a scheduling mechanism that combines priority-awareness, fog resource tiering, and overload handling, while remaining practical and adaptable for real-time healthcare workloads.

Problem Formulation

This section defines and formalizes the proposed priority-based task allocation and scheduling problem in a fog computing environment by specifying the task model, fog resource (fog node) model, decision variables, constraints, and optimization objectives. The formulation reflects an IoT-enabled healthcare monitoring scenario, where patient-

related tasks arrive dynamically at the edge and must be processed under strict urgency requirements and heterogeneous fog resource capabilities.

Problem Definition

Fog-assisted healthcare monitoring generates a continuous stream of service requests such as routine vital-sign updates, follow-up processing, and start/end assessments. However, these tasks are not equally critical in real-time healthcare operations. Some tasks may indicate abnormal clinical conditions and require immediate processing, whereas routine monitoring tasks can tolerate small delays. If scheduling is performed using a simple first-come-first-served approach or without urgency awareness, critical healthcare tasks may experience unacceptable waiting time, leading to delayed response actions and potential SLA violations. In fog computing, computation is intentionally placed closer to IoT devices to reduce network delay and support faster decision-making. At the same time, fog environments are distributed and heterogeneous, meaning that fog nodes differ in processing capability, availability, and operational role. Therefore, fog resources cannot be treated as identical units. Instead, fog nodes can be logically categorized into multiple capability tiers (for example, high-capability fog nodes, mid-tier fog nodes, and lightweight fog gateways), similar to how healthcare workflows depend on different levels of clinical expertise. Hence, the problem is to allocate each incoming healthcare task to an appropriate fog node category and schedule the execution order within each category such that high-priority tasks receive faster service while maintaining overall system stability. The objectives are to minimize waiting time and end-to-end response time (especially for critical tasks), reduce SLA/deadline violations, maintain good throughput and fog resource utilization, and handle congestion effectively through a controlled spillover strategy when the preferred fog tier becomes overloaded.

Task Model

In the proposed fog-based healthcare monitoring system, a task represents a processing request generated by IoT devices or health monitoring applications, such as periodic vital-sign updates, event-triggered alerts, medical follow-up processing, and start/end assessment requests. Tasks arrive dynamically at the fog gateway and are characterized by a set of attributes that influence allocation and scheduling decisions.

Let the stream of incoming tasks be represented as:

$$T = \{t_1, t_2, \ldots, t_n\}$$

Each task $t_i$is described using the following parameters:

- Arrival time (a_i): time when the task reaches the fog gateway.
- Computation demand (l_i): workload length in million instructions (MI).
- Deadline (optional) (d_i): acceptable completion time for SLA compliance.
- Priority class (p_i): urgency level assigned to the task.
- Service type (s_i): healthcare operation type (routine update, follow-up, start/end assessment, emergency event).

Since fog-based healthcare workloads contain mixed criticality, the incoming tasks are grouped into three priority levels:

- P_1: High-priority/critical tasks (emergency or risk-indicating events)
- P_2: Medium-priority tasks (follow-ups and clinically important requests)
- P_3: Low-priority tasks (routine monitoring and start/end assessments)

This classification ensures that urgent healthcare events are processed ahead of delay-tolerant workloads in the fog layer.

Fog Resource (Fog Node) Model

Fog computing resources consist of geographically distributed nodes deployed closer to IoT devices, such as healthcare gateways, edge servers, and micro data centers. Unlike centralized cloud environments, fog nodes are heterogeneous in terms of processing capacity, memory availability, and service responsiveness. Therefore, fog nodes must be modeled as capability-aware resources rather than identical units.

Let the set of available fog nodes be:

$F = \{f_1, f_2, \ldots, f_m\}$
Each fog node f_j is characterized by:

- Processing capability (C_j): CPU speed measured in MIPS
- Available memory $(M_j)$and storage (S_j)
- Current load (U_j): utilization/queue occupancy
- Execution queue (Q_j): local task queue at the fog node
- Network latency (L_j): communication delay between IoT source and the fog node (fog-layer delay)

To enable structured allocation, the fog nodes are grouped into three capability tiers:

- FN_1(High-capability fog tier): suitable for urgent and time-critical tasks
- FN_2(Mid-tier fog): suitable for moderate tasks and general processing
- FN_3(Lightweight fog/gateway tier): suitable for routine and background processing

This categorization supports efficient task matching in PBTA-S, where resource tiers serve a role similar to expertise levels in healthcare workflows.

Decision Variables

The task allocation and scheduling problem is defined using decision variables that represent task-to-fog-node mapping and execution ordering within each fog tier.

Allocation Variable

Let:

$$x_{ij} = \begin{cases} 1 & \text{if task } t_i \text{ is assigned to fog node } f_j \\ 0 & \text{otherwise} \end{cases}$$

Fog Tier Selection

Each task is first mapped to a fog tier based on its priority:

$$tier(t_i) \in \{FN_1, FN_2, FN_3\}$$

Scheduling Order Variable

Let $o_i$represent the execution position of task $t_i$inside its tier queue. PBTA-S ensures priority ordering while maintaining stable ordering within the same class.

Constraints

The fog-based scheduling process is subject to the following constraints:

C1: Unique Assignment Constraint

Each task must be assigned to exactly one fog node:

$$\sum_{j=1}^{m} x_{ij} = 1, \forall t_i \in T \quad (1)$$

C2: Fog Node Capacity Constraint

A fog node can only handle tasks within its available processing and memory limits:

$$\text{load}(f_j) \leq \text{capacity}(f_j)$$

C3: Priority-to-Tier Mapping Constraint

Urgent tasks should be directed to higher-capability fog tiers unless congestion forces spillover:

- $P_1 \rightarrow FN_1$
- $P_2 \rightarrow FN_2$
- $P_3 \rightarrow FN_3$

C4: Waiting-Time Threshold / Spillover Constraint

If the predicted waiting time of a task in the preferred tier exceeds a predefined threshold θ, the task can be shifted to the nearest available fog tier:

$$W_i > \theta \Rightarrow \text{spillover}(t_i)$$

This constraint prevents excessive delay for higher-priority tasks under overload conditions.

C5: Deadline / SLA Constraint (Optional)

For tasks with deadlines, completion must ideally occur within:

$$c_i \leq d_i$$

where $c_i$is the completion time.

Objective Functions

The proposed PBTA-S mechanism is formulated to perform priority-based task allocation and scheduling for healthcare monitoring using multi-level fog node categorization in a fog computing environment. The optimization goal is to ensure that critical healthcare tasks receive faster and more reliable service by reducing waiting time and end-to-end response time, while also minimizing SLA/deadline violations, improving throughput, and maintaining balanced fog resource utilization under dynamic workload conditions.

Objective 1: Minimize End-to-End Response Time

Fog response time includes both processing and fog-layer communication delay:

$$\min \sum_{i=1}^{n} R\,T_i \tag{2}$$

where

$$RT_i = (\text{execution time}) + (\text{waiting time}) + (\text{fog network delay})$$

Objective 2: Minimize Waiting Time for Critical Tasks

PBTA-S prioritizes reducing queue waiting delay particularly for P_1:

$$\min \sum_{t_i \in P_1} W_i \tag{3}$$

Objective 3: Minimize SLA/Deadline Violations

The number of tasks missing their SLA target should be minimized:

$$\min \sum_{i=1}^{n} V_i \tag{4}$$

where $V_i = 1$if task $t_i$violates deadline/SLA, else 0.

Objective 4: Maximize Throughput

The number of successfully completed tasks per unit time should be maximized:

$$\max \text{Throughput}$$

Objective 5: Maintain Balanced Fog Utilization

PBTA-S aims to prevent overload on specific fog tiers and promote stable utilization:

$$\min \max_j (U_j)$$

The proposed fog-based scheduling model considers an online task arrival scenario, where healthcare-monitoring requests are generated continuously by IoT devices and enter the fog layer dynamically over time rather than being available as a fixed batch. Once a task is allocated to a selected fog node and execution begins, preemption is not performed, meaning the task runs until completion. This design choice avoids runtime overheads such as state checkpointing, context switching, and task migration, which may be costly in distributed fog environments. Nevertheless, the framework can be extended to support preemptive handling for emergency tasks when strict clinical urgency demands immediate execution. Each fog node is assumed to follow a single-task execution model, where only one task is processed at a time (i.e., node-level concurrency is set to 1) to ensure clear scheduling behavior and reproducible evaluation. Finally, spillover across fog tiers is permitted only under congestion, and assigning a task outside its preferred fog category is treated as a controlled and limited exception. During performance evaluation, such spillover events can be explicitly measured using a penalty factor or reported as a tier-violation rate, reflecting the practical trade-off between strict capability alignment and timely response requirements for critical healthcare tasks.

Proposed PBTA-S Model

This section presents the proposed Priority-Based Task Allocation and Scheduling (PBTA-S) mechanism tailored for fog-assisted IoT healthcare monitoring. The model is designed to process mixed-criticality tasks (critical, moderate, routine) in a distributed fog environment by combining priority-aware task classification, multi-level fog node categorization, tier-specific queue management, and an overload-aware spillover strategy. The key intention of PBTA-S is to minimize waiting and response time for high-priority healthcare tasks while maintaining stable fog resource utilization under fluctuating arrivals. The proposed PBTA-S framework is designed to support latency-sensitive healthcare monitoring by performing priority-aware task allocation and scheduling within a fog computing environment. Incoming tasks generated by IoT devices are first analyzed and classified into urgency levels, after which they are mapped to capability-aware fog tiers to ensure appropriate resource matching. PBTA-S then organizes tasks into tier-specific queues and dispatches them to the least-loaded fog nodes for execution under a non-preemptive model. To maintain stable performance during burst arrivals, the framework further incorporates an overload-aware spillover mechanism that redirects tasks only when the expected waiting time in the preferred tier exceeds a predefined threshold. As shown in Figure 1, this architecture enables structured handling of mixed-criticality workloads while improving responsiveness for high-priority healthcare tasks.

Figure 1 illustrates the overall workflow of the proposed PBTA-S framework deployed in a fog computing environment for IoT-enabled healthcare monitoring. Healthcare tasks generated from edge devices are received at the fog gateway and dynamically processed in an online manner. Each incoming task is classified into a priority level (P1, P2, or P3) based on clinical urgency and then mapped to an appropriate fog resource tier (FN1, FN2, or FN3) that reflects different capability levels. PBTA-S maintains independent priority queues for each fog tier, enabling structured and urgency-aware task ordering. The fog scheduler selects tasks from the queues and dispatches them to the least-loaded fog node within the preferred tier using a non-preemptive execution model. During congestion, the framework activates a controlled spillover mechanism based on waiting-time thresholds to prevent critical tasks from being blocked by long queues. The monitoring and feedback module continuously records performance measures such as waiting time, end-to-end response time, SLA violations, fog-tier utilization, and tier-violation rate, which supports stable scheduling decisions under varying workload conditions.

Overview of the PBTA-S Fog Workflow

In a fog-based healthcare monitoring environment, tasks are generated continuously from IoT devices and reach the fog layer through a gateway or edge controller. PBTA-S processes each task through the following stages:

- **Task Arrival at Fog Gateway**

Incoming healthcare tasks are received dynamically and stored temporarily at the gateway for classification.

- **Priority Classification (P1, P2, P3)**

Each task is assigned a priority label based on urgency:

  - P1: critical / emergency / risk-indicating tasks
  - P2: moderate tasks (follow-up, high clinical relevance)
  - P3: routine monitoring and start/end assessments

- **Fog Node Tier Mapping (FN1, FN2, FN3)**

Fog nodes are grouped into capability tiers:

  - FN1: high-capability fog tier (closest micro-datacenter / hospital edge server)
  - FN2: mid-tier fog (regional edge server / MEC node)
  - FN3: lightweight fog (gateway-class resources)

- **Tier-Specific Queue Assignment (Q1, Q2, Q3)**

Tasks are inserted into the queue corresponding to their fog tier.

- **Fog Node Selection and Dispatch**

PBTA-S selects the **least-loaded node** inside the chosen tier and dispatches the task for execution.

- **Overload-Aware Spillover (Congestion Handling)**

If the predicted waiting time for a task exceeds a threshold, PBTA-S triggers controlled spillover to a suitable adjacent tier to avoid long delays.

PBTA-S Fog Scheduling Components

Priority Analyzer

The priority analyzer identifies the urgency level of each healthcare task using predefined rules. For example:

- abnormal sensor patterns or alarm conditions → P1
- follow-up tasks and escalations → P2
- periodic monitoring / start-end logs → P3

This ensures urgent tasks are always positioned ahead of routine workloads in the fog layer.

Fog Tier Categorizer

Fog nodes are categorized into tiers based on resource capability (CPU speed, memory, historical performance, and reliability). The categorization helps PBTA-S ensure that critical workloads are processed on stronger fog resources.

Tier policy:

- P1 tasks are mapped to FN1
- P2 tasks are mapped to FN2
- P3 tasks are mapped to FN3

Queue Manager (Tier-Specific Queues)

PBTA-S maintains independent queues at the fog controller:

- Q_1→ tasks mapped to FN1
- Q_2→ tasks mapped to FN2
- Q_3→ tasks mapped to FN3

Within each queue, tasks are ordered based on scheduling keys such as:

- higher urgency first
- earlier arrival first (within same priority)
- deadline sensitivity (optional)

Fog Dispatcher and Node Selection

When a task reaches the head of a queue, PBTA-S selects a fog node from the corresponding tier using a **least-loaded selection rule**, such as:

- lowest current utilization
- shortest queue length
- earliest expected availability

This improves load balance and prevents certain fog nodes from becoming bottlenecks.

Congestion Controller and Spillover Strategy

Fog resources may experience burst workloads, especially in healthcare environments during abnormal monitoring conditions. PBTA-S introduces a controlled spillover strategy:

- If the estimated waiting time in the preferred tier exceeds a threshold θ, the task may be redirected to the nearest feasible tier.
- Spillover is applied as an exception and not as a default.

Example spillover rules:

- FN1 overloaded → redirect some tasks to FN2 (for continuity)
- FN2 overloaded → redirect to FN3 (for non-critical tasks)
- FN3 overloaded → redirect to FN2 (if capacity exists)

This prevents urgent tasks from being stuck in long queues during fog congestion.

PBTA-S Fog Algorithm

Algorithm: PBTA-S for Fog Task Allocation and Scheduling

Input:

Task stream T, fog node sets FN_1, FN_2, FN_3, queues Q_1, Q_2, Q_3, waiting threshold θ

Output:

Priority-aware task execution with minimized delay and controlled spillover

Steps:

1. When a task t_i arrives at the fog gateway, extract attributes (a_i, l_i, p_i)
2. Assign task priority class:
   - If critical → P_1
   - Else if moderate → P_2
   - Else → P_3
3. Map the task to fog tier:
   - $P_1 \rightarrow FN_1$
   - $P_2 \rightarrow FN_2$
   - $P_3 \rightarrow FN_3$
4. Insert task into the corresponding queue Q_k
5. While queue Q_k is not empty:
   - Select the head task t_i
   - Estimate waiting time W_i in preferred tier
   - If $W_i \leq \theta$
     Dispatch t_i to the least-loaded fog node in the preferred tier
   - Else
     Activate spillover and dispatch t_i to the nearest feasible tier with minimum predicted waiting
6. Execute task non-preemptively to completion at the selected fog node
7. Update node status and queue statistics (waiting time, completion time, violations)

Handling Spillover and Tier-Violation Rate

Since PBTA-S is designed for fog environments where capability alignment matters, spillover must be treated as a controlled exception. To quantify spillover impact, a tier-violation rate (TVR) can be computed as:

$$TVR = \frac{\text{Number of tasks executed outside preferred tier}}{\text{Total tasks executed}} \quad (5)$$

A lower TVR indicates stricter alignment between task urgency and fog tier capability, while a slightly higher TVR may be acceptable under heavy congestion to protect urgent tasks from long delays.

Optionally, a spillover penalty can be added in performance evaluation:

$$Penalty(t_i) = \begin{cases} 0 & \text{if executed in preferred tier} \\ \lambda & \text{if executed in non-preferred tier} \end{cases}$$

where λ reflects the operational cost or reduced suitability of executing tasks outside the optimal tier.

Time Complexity Discussion

The computational cost of PBTA-S primarily depends on:

- task classification: $O(1)$ per task
- queue insertion: $O(\log n)$ if priority queue is used, else $O(1)$ for FIFO
- node selection inside tier: $O(m)$ for scanning nodes, or $O(\log m)$ using a heap structure

Therefore, PBTA-S remains efficient and suitable for real-time fog scheduling where tasks arrive continuously.

Experimental Setup and Evaluation

This section describes the experimental setup and evaluation methodology used to validate the performance of the proposed PBTA-S framework using the CloudSim simulator. Although PBTA-S is motivated by fog-assisted healthcare monitoring, its tiered scheduling behavior can be effectively modeled in CloudSim by representing fog capability tiers as heterogeneous VM pools and implementing the scheduling logic at the broker level. The key objective of PBTA-S is to improve the responsiveness of mixed-criticality healthcare monitoring workloads by prioritizing urgent tasks, reducing queueing delay, and controlling congestion through spillover. The experimental evaluation compares PBTA-S against baseline scheduling strategies under varying workload intensities to quantify improvements in waiting time, response time, SLA/deadline violations, throughput, and VM utilization. The experiments are conducted using CloudSim, a widely used simulation toolkit for modeling cloud datacenters, virtualized resources, and task scheduling policies. CloudSim enables controlled evaluation of resource allocation algorithms by allowing configuration of datacenter hosts, VM provisioning, Cloudlet execution, and broker-driven task assignment. In this study, CloudSim is used to emulate a healthcare computing environment in which tasks arrive dynamically over time and must be scheduled efficiently on heterogeneous VM resources. By introducing multi-level VM categorization and queue-based dispatching in the broker, the proposed PBTA-S framework can be evaluated under reproducible conditions with consistent workload patterns and resource configurations.

Cloud Sim Infrastructure Configuration and Load Modeling

To emulate heterogeneous fog/edge capability within a CloudSim environment, the simulation is configured with three VM categories representing high-, mid-, and lightweight execution tiers, so that tasks can be allocated based on urgency and resource suitability. A typical VM configuration follows three capability pools: **C1** for critical tasks, **C2** for medium tasks, and **C3** for routine tasks, with compute and memory ranges summarized in Table 1 (e.g., C1: 2–4 VMs with 8000–12000 MIPS; C2: 3–6 VMs with 4000–8000 MIPS; C3: 4–8 VMs with 1000–4000 MIPS, with corresponding RAM ranges).

Incoming healthcare tasks are modeled as Cloudlets characterized by arrival time, computation length (MI), and an optional deadline/SLA target. To reflect mixed-criticality monitoring, tasks are grouped into P1/P2/P3 classes (P1: critical abnormal events; P2: clinically significant follow-ups; P3: routine/start-end updates), and Cloudlets arrive dynamically in an online mode under three workload intensities—light, medium, and heavy (bursty)—with typical proportions of P1: 15–25%, P2: 25–35%, P3: 40–60%. PBTA-S is implemented through a custom CloudSim broker that tags Cloudlets by priority, maps them to VM categories (C1/C2/C3), inserts them into independent category-specific queues (served in the order $Q1 > Q2 > Q3$), and dispatches tasks to the least-loaded VM in the preferred category; spillover is activated only when predicted waiting exceeds a threshold, and spillover events are logged for tier-violation analysis.

Load definition (utilization ratio): In this work, "load" is defined using the offered-load (utilization) ratio ρ, which measures how strongly the incoming workload stresses the available VM capacity. Specifically,

$$\rho = \frac{\lambda \cdot \mathbb{E}[L]}{\mu_{tot}} \tag{6}$$

where $\lambda$is the Cloudlet arrival rate (tasks/s), $\mathbb{E}[L]$is the mean Cloudlet computation demand (MI), and μ_{tot} is the total VM service capacity (MI/s). In CloudSim terms, μ_{tot} is computed from VM speeds as:

$$\mu_{tot} = \sum_{j=1}^{m} (MIP S_j \times PE_j) \tag{7}$$

(when each VM has one processing element, $PE_j = 1$, then $\mu_{tot} = \sum MIPS_j$). We categorize workload intensity using the following cut-offs:

- Light load: $0 < \rho \leq 0.4$
- Medium load: $0.4 < \rho \leq 0.8$

- Heavy (bursty) load: $0.8 < \rho \leq 1.2$

where $\rho > 1$represents temporary overload (arrivals exceed service capacity), leading to queue buildup and congestion—precisely the condition under which spillover becomes beneficial. These load definitions correspond to the "light/medium/heavy" settings used to report response time and other QoS outcomes in the results tables (e.g., Table 2).

RESULTS AND DISCUSSION

This section evaluates the performance of the proposed PBTA-S framework using the Cloud Sim simulator and compares it with baseline approaches including FCFS, Priority Scheduling (PS), Load-Based Scheduling (LB), and Tiered Scheduling without Spillover (TS) under light, medium, and heavy workload conditions. The evaluation focuses on key indicators for mixed-criticality healthcare workloads, such as average response time, average waiting time (especially for P1 tasks), SLA/deadline violation rate, throughput, VM utilization balance across categories, and the category-violation rate introduced by spillover. As shown in Table 2, response time trends remain similar across methods under light load due to minimal queueing, but differences become significant as demand increases; FCFS performs worst due to its non-priority behavior, PS improves responsiveness through urgency ordering, LB improves balancing without strong urgency guarantees, and TS benefits from tiering but loses flexibility under overload, whereas PBTA-S consistently achieves the lowest response time, with the largest improvement under heavy load.

For critical healthcare tasks, reducing queue delay is essential, and Table 3 shows that PBTA-S achieves the minimum waiting time for P1 emergency tasks across all load levels by prioritizing Q1, selecting the least-loaded VM within the high-capability category, and using spillover only when congestion would otherwise cause excessive delay. SLA and deadline compliance is a key QoS requirement in time-sensitive healthcare processing. As reported in Table 4, PBTA-S produces the lowest violation rates under all workload intensities, particularly during heavy-load conditions, indicating that urgency-driven scheduling combined with controlled spillover improves deadline adherence more effectively than FCFS, PS, LB, and strict tiering without spillover. In terms of system stability, throughput comparisons in **Table 5** indicate that all methods perform similarly under light load, whereas PBTA-S maintains the highest throughput under medium and heavy loads by avoiding category-level bottlenecks through least-load dispatching and preserving continuity during overload via spillover. Resource efficiency is validated through utilization balance across VM categories. Under heavy load, Table 6 shows that FCFS and PS tend to overload high-capability VMs while leaving lower tiers underused, and TS can saturate the top tier due to strict mapping. PBTA-S achieves a more balanced utilization profile across categories by selecting the least-loaded VM within each tier and activating spillover only when required, thereby improving both responsiveness and stability

Finally, PBTA-S introduces spillover as a controlled exception to prevent excessive delays when the preferred category is congested. As presented in Table 7, TS reports a category-violation rate of 0% due to strict tier enforcement, while PBTA-S shows a small CVR/TVR because it permits limited redirection to maintain responsiveness. This slight category deviation is justified by the substantial reductions achieved in response time and SLA violations under heavy load, and TVR is computed only for tier-aware methods since non-tiered baselines do not define preferred execution categories. The Cloud Sim-based evaluation confirms that PBTA-S consistently delivers the best performance across light, medium, and heavy-load scenarios by achieving the lowest response time, minimizing waiting delay for critical tasks, reducing SLA violations, maintaining higher throughput under burst arrivals, and balancing VM utilization across categories. The controlled spillover mechanism introduces only limited category violations while providing strong congestion resilience, demonstrating that combining urgency-driven prioritization with multi-level VM categorization and overload-aware scheduling is an effective strategy for time-sensitive healthcare monitoring workloads.

CONCLUSION AND FUTURE WORK

This paper proposed PBTA-S, a priority-based task allocation and scheduling framework for IoT-enabled healthcare monitoring, where tasks are generated continuously and must be processed within strict time constraints under mixed-criticality conditions. PBTA-S classifies healthcare tasks into three urgency levels and maps them to heterogeneous VM categories representing different capability tiers, enabling category-specific queue scheduling and least-load VM dispatching to improve responsiveness under dynamic workloads. A controlled spillover mechanism is activated only during congestion to prevent critical tasks from being delayed by long queues, thereby reducing waiting time and overall response time while lowering SLA/deadline violations during burst arrivals, without compromising throughput and utilization stability across VM categories. Future work will focus on enhancing task prioritization using clinical severity scoring derived from real sensor patterns and patient context, improving spillover decisions through adaptive thresholds driven by runtime feedback or lightweight learning models, and extending the framework with energy-aware scheduling for efficient resource usage. Additional improvements include incorporating privacy-aware processing and secure data handling, strengthening fault tolerance under VM or host failures, enabling mobility-aware execution for dynamic monitoring environments, and integrating fairness-aware mechanisms that provide bounded delays for non-critical workloads while maintaining strict urgency guarantees for emergency healthcare tasks.

ABSTRACT

In the world of *Ayurveda*, there is a highly individualized approach to measuring the human body known as *Pramana Sharir*. Rather than relying on universal, standardized units like inches or centimeters, it uses the patient's own anatomy—specifically, their finger width (*Swa-Angula Pramana*)—as the core metric. However, there has been a noticeable lack of systematic research connecting these ancient anatomical rules to modern scientific standards. This review was built to tackle four main goals: (1) break down the foundational concepts of *Pramana Sharir* from authoritative classical texts, (2) see how these ancient metrics map onto modern measurement systems, (3) figure out if there is actual, solid evidence for using this in medicine and forensics today, and (4) pinpoint exactly where more research is desperately needed.
We combed through major databases (PubMed, Scopus, and Google Scholar) for studies published between 2010 and 2025. We also analyzed authoritative English translations of heavy-hitting classical texts like the *Charaka Samhita* and *Sushruta Samhita [1,2]*. Following PRISMA 2020 guidelines, two independent reviewers vetted the study selection and evaluated the risk of bias using JBI Critical Appraisal Tools. We started with 847 records and narrowed it down to 32 solid studies. The ancient texts outline a highly detailed system for measuring both linear length (using finger-breadths, or *Anguli*) and volumetric capacity (using cupped hands, or *Anjali*). Historically, having perfectly balanced body proportions was thought to guarantee a longer, healthier life. Today, we found these measurements being

applied in surgical planning, pharmacology, and forensic identification. While the evidence moderately supports the physical measurement applications, there is very little proof validating the historical claims about lifespan. *Pramana Sharir* offers a fascinating, custom-tailored framework for evaluating the human body, with moderate scientific evidence backing up its practical measurement applications. That being said, we need long-term modern studies before this system can be fully integrated into everyday clinical practice.

Keywords: *Pramana Sharir*, *Ayurvedic* anthropometry, *Swa-Angula Pramana*, systematic review, PRISMA, personalized medicine

INTRODUCTION

Ayurveda looks at human health as a complete package—a balancing act of mind, body, and spirit. On the physical side of things, *Pramana Sharir* is the traditional method used to measure and evaluate the body's structure. If we break down the Sanskrit, "*Pramana*" essentially means a valid way to gain knowledge, while "*Sharir*" refers to the physical form itself. While plenty of ancient cultures had their own ways of measuring people, *Ayurveda* did something entirely unique: it used the individual's own body as the ruler. By using the width of a person's own finger (known as *Anguli Pramana* or *Swa-Angula*), *Ayurvedic* practitioners acknowledged that everyone has a unique physical constitution that demands a customized assessment.

Classical Foundations

The foundational authorities of ancient *Ayurveda*—including *Charaka, Sushruta*, and *Vagbhata*—wrote extensively about these measurement protocols. *Charaka* actually made it a core part of his ten-step patient examination to figure out a person's physical strength and overall prognosis[1]. Sushruta took the concept even further, arguing that a perfectly proportioned body directly correlated with enhanced longevity, establishing a direct link between structural harmony and a long life [2].

Contemporary Context

Fast forward to today, and modern anthropometry traces its roots back to 19th-century criminal identification, eventually expanding into clinical medicine, ergonomics, and sports science [10,13,14]. Today, clinical practice relies heavily on standardized metrics like Body Mass Index (BMI), Waist-to-Hip Ratio (WHR), and Body Surface Area (BSA) to figure out nutritional health and stratify disease risk [15].

Rationale and Research Question

There is a massive gap when it comes to systematically blending these ancient, personalized rules of *Ayurvedic* anthropometry with modern empirical validation. This review asks a straightforward question: What is the current scientific evidence backing up the principles and practical applications of *Pramana Sharir* today?

Objectives

- Systematically pull the core rules of *Pramana Sharir* from classical *Ayurvedic* texts.
- Establish how these ancient measurement concepts compare to modern approaches.
- Critically judge the quality of evidence supporting their use in clinical and forensic settings.
- Highlight significant gaps where further scientific investigation is needed.

MATERIALS AND METHODS

Study Design: To ensure our methodology was rigorous and completely transparent, this systematic review strictly followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 guidelines.
Search Strategy: On January 15, 2025, we ran deep, comprehensive searches across major electronic databases. We blended traditional keywords (like "*Pramana Sharir*" and "*Anguli Pramana*") with modern scientific terms (like "forensic anthropology" and "body composition") to cast a wide net across PubMed, Scopus, and Google Scholar.
Study Selection Process: Using Rayyan QCRI software, two independent reviewers filtered the retrieved records. They first screened titles and abstracts, then pulled the full texts of potentially eligible studies for a much closer look. The two reviewers had a remarkably strong agreement rate (Cohen's kappa = 0.87), and any minor disagreements were settled through discussion.

Sources of Information

Classical Ayurvedic Literature

We analyzed primary texts including the *Charaka Samhita, Sushruta Samhita, Ashtanga Hridaya, Ashtanga Sangraha, Kashyapa Samhita, Bhela Samhita, Sarangadhara Samhita,* and *Vangasena Samhita [1-8].*

Modern Scientific Sources

We gathered recent papers on forensics, clinical anatomy, and anthropometry from databases like PubMed, Scopus, and Google Scholar. The search was locked strictly to English-language articles published between 2010 and 2025

Inclusion and Exclusion Criteria

Data Extraction

Two reviewers independently pulled the data using a standardized extraction form. For the modern studies, we grabbed details on the authors, study design, demographics, measurement tools, and the hard numbers (like p-values and correlation coefficients). For the classical texts, we extracted all relevant passages regarding *Anguli Pramana*, *Anjali Pramana,* and body proportionality.

Quality Assessment (Risk of Bias)

The reviewers judged the methodological quality of the included studies using JBI Critical Appraisal Checklists tailored to the specific study designs (such as cross-sectional or cadaveric studies). Studies scoring 80% or higher were graded "High quality," 60–79% earned a "Moderate" grade, and anything below 60% was marked "Low.

Data Synthesis

Because the studies varied wildly in their setups, outcome measures, and populations, a meta-analysis was impossible. Instead, we wrote a narrative synthesis organized around three main themes: classical measurement principles, ancient body proportions, and the modern scientific validation of those concepts.

RESULTS

Study Selection Results

Our initial database searches kicked back 847 records. After scrubbing the duplicates and screening the abstracts, we closely reviewed 74 full-text articles. We ended up rejecting 42 of them (mostly because they lacked original data or measurable proportions), leaving us with 32 solid studies for the final analysis—comprising 9 text analyses and 23 modern validation studies.

PRISMA 2020 Flow Diagram

Records identified (n = 847)

PubMed (n = 312)
Scopus (n = 289)
Google Scholar (n = 246)
↓
Records after duplicates removed (n = 563)
↓
Records screened (n = 563) → Records excluded (n = 489)
↓
Full-text articles assessed (n = 74) → Full-text excluded (n = 42)
• No original data (n = 18)
• No measurable proportions (n = 15)
• Non-English (n = 6)
• Pre-2010 (n = 3)
↓
Studies included in review (n = 32)
Classical text analyses (n = 9)
Modern validation studies (n = 23)

Conceptual Basis of *Pramana Sharir*

Meaning of *Pramana*: In *Ayurvedic* philosophy, *Pramana* is the valid acquisition of knowledge. *Charaka* laid out four primary ways to get it: reliable authority (*Aptopadesha*), direct observation (*Pratyaksha*), inference (*Anumana*), and logical reasoning (*Yukti*) [1]. Systems of Measurement in Ayurveda: P Classical texts mention several regional measurement systems. Generally, they categorize measurements into three buckets: linear length, physical weight, and liquid volume [9].

Anguli Pramana* vs. *Anjali Pramana

Concept of *Sama Sharir:* If a person's arm span perfectly matches their total body height, they possess what is called *Sama Sharir*[2]. Historically, individuals with this perfect proportion were believed to have a longer lifespan, greater physical strength, and rock-solid immunity.

DISCUSSION

Summary of Principal Findings

Our deep dive into the 32 studies shows that *Pramana Sharir* is a highly sophisticated, individualized framework for measuring the body. Using a person's own finger width as a base unit actually mirrors modern practices that use ratios to account for different body sizes across varying populations. We found these measurements being practically applied in everything from forensic identification to customized surgical planning.

Alignment with Allometry

This self-referential system aligns perfectly with the biological principle of allometry—the study of how body proportions shift and change with overall size [23]. This suggests that *Ayurveda* figured out centuries ago that biological ratios matter far more than absolute numbers.

Comparison with Modern Anthropometry

Certainty of Evidence Assessment

Using GRADE (Grading of Recommendations Assessment, Development and Evaluation) principles adapted for narrative synthesis, we assigned the following certainty grades to major claims:

Strengths and Weaknesses of the Review

Strengths

The brilliance of this system is that it doesn't require external tools—the patient is the measuring stick. It seamlessly links physical size to functional health, and its direct clinical and forensic applications are highly relevant today.

Weaknesses (including language bias)

The biggest flaw is how difficult it is to standardize what a "finger width" actually means across different research clinics. Additionally, by restricting our search strictly to English papers published between 2010 and 2025, we likely missed older, foundational studies as well as valuable research published in Indian languages like Hindi or Sanskrit.

Future Research Directions

To really pull *Pramana Sharir* into the 21st century, researchers need to use MRI and 3D imaging to map these ancient external measurements onto actual internal anatomy. We also need massive demographic databases to establish what normal *Ayurvedic* proportions look like across different ethnic groups today. Finally, longitudinal studies are essential to see if these proportions actually do predict a longer lifespan.

CONCLUSION

Pramana Sharir is a fiercely individualized way of looking at human anatomy that traces its roots back to classical *Ayurvedic* medicine. Instead of relying on universal averages, it uses the patient's own body as the baseline, offering a customized approach that pairs beautifully with standardized modern metrics. In forensics, it can improve regression formulas, and in clinical settings, it can add a personalized layer to conventional risk assessments. While we definitely need more large-scale research to validate the bolder historical claims, this system has immense potential to make our understanding of human health much more holistic and personalized.

Conflict of Interest Statement

The authors declare no conflict of interest.

Funding Statement

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Table 1: Inclusion and Exclusion Criteria

Parameter	Inclusion Criteria	Exclusion Criteria
Classical Texts	Sanskrit commentaries with English translations available	Texts lacking commentary or reliable translation
Modern Literature	Peer-reviewed original research, systematic reviews, narrative reviews	Conference abstracts, unpublished data, non-English publications
Publication Date	Classical: any edition; Modern: 2010-2025	Modern literature pre-2010
Subject Relevance	Direct relevance to Pramana Sharir or anthropometric measurement	No measurable body proportion data presented

Table 2: Quality Assessment Grades

Reference	Study Design	JBI Score	Quality Grade
Mehta & Joshi (2021)[20]	Cadaveric validation	8/10	High
Kumar & Singh (2023)[29]	3D photogrammetry validation	7/10	Moderate
Sharma et al. (2021)[27]	Cross-sectional	6/10	Moderate
Singh et al. (2020)[16]	Cross-sectional	7/10	Moderate
Rao & Reddy (2020)[26]	Cross-sectional	4/10	Low
Patel & Thakur (2022)[18]	Pilot cross-sectional	5/10	Low

Table 3: Comparison *of Anguli* and *Anjali Pramana*

Feature	*Anguli Pramana*	*Anjali Pramana*
Measurement Type	Linear dimensions	Volumetric capacity
Unit Basis	Individual finger breadth	Capacity of joined palms
Clinical Applications	Height assessment, surgical instrument sizing, *Marma* point localization	Body fluid quantification (*Rasa*, *Rakta*, etc.)
Example	84 *Angula* for total body height	9 *Anjali* for *Rasa*

Table 4: Ideal Body Height in Classical Texts

Text	Height(*Angula*)	Special Condition
Charaka Samhita[1]	84	Measured standing erect, feet together, heel to crown
SushrutaSamhita[2]	120	Standing with arms extended vertically overhead, fingertip to fingertip
Ashtanga Hridaya[3]	3.5× forearm length	Height derived by multiplying forearm length (elbow to middle fingertip) by 3.5

Table 5: Clinical Applications of *Pramana Sharir*

Specialty	Application	Example
Shalya Tantra (Surgery)[2]	Surgical instrument design	Needles: 2 *Angula* (delicate), 3 *Angula* (muscular)
Marma Therapy[33]	Vital point localization	Measurement-based identification
Panchakarma[3]	Basti instrument length	*Bastinetra*: ~12 *Angula*
Dravyaguna[4]	Plant morphology description	Standardized references
Rasashastra[8]	Pharmaceutical dimensions	Material sizing
Forensic Medicine[16,17,19,20]	Stature from partial remains	Height from nose/ear/foot length

Table 6: *Ayurvedic* vs Modern Anthropometry Comparison

Aspect	Ayurvedic System	Modern System
Philosophical Basis	Personalized, holistic (physical-functional integration)	Standardized, primarily physical
Unit of Measurement	*Swa-Angula Pramana* (individual finger breadth)	Standardized units (cm, inches, kg)
Key Indices	Total height (84-120 Angula), *Sama Sharir*	BMI, WHR, skinfold thickness
Clinical Use	Prognosis (*Ayushya Pramana*), surgical planning	Nutritional assessment, disease risk

ABSTRACT

Adenoid hypertrophy is a common paediatric condition and a major cause of upper airway obstruction in children. It may lead to nasal obstruction, mouth breathing, recurrent infections, sleep disturbances, and impaired quality of life. Although adenoidectomy is commonly recommended in severe cases, adenoid hypertrophy is considered a pseudo-surgical condition in which conservative management may be beneficial. This literature-based review highlights the anatomy, etiopathogenesis, clinical features, diagnosis, and conventional management of adenoid hypertrophy, with special emphasis on the homoeopathic perspective. Homoeopathy approaches the condition as a manifestation of an underlying constitutional disturbance and aims to restore health through individualized treatment. The review suggests a potential role for homoeopathy in the management of adenoid hypertrophy while pointing out the need for further scientific research to strengthen the existing evidence base.

Keywords: Adenoid Hypertrophy; Homoeopathy; Pseudo-Surgical Conditions; Paediatric Airway Obstruction; Individualized Treatment

INTRODUCTION

Pseudo-surgical diseases are clinical conditions for which surgical treatment is often recommended when significant local pathological changes are present. However, surgery is not necessary for all of these conditions, as many can be

effectively managed with conservative, non-surgical therapies. They commonly present with chronic, relapsing, or structural abnormalities, giving an impression of requiring surgical treatment when satisfactory results can be obtained with other modes of management. Some common examples are adenoid hypertrophy, chronic tonsillitis, renal calculi, warts, corns, ovarian cysts and fistula-in-ano. Pseudo-surgical conditions emphasize the need to consider more conservative treatment options before surgery.[1] Waldeyer's lymphatic ring is a circular arrangement of lymphoid tissue located in the pharynx and comprises four components: the adenoid (nasopharyngeal tonsil), tubal tonsils, palatine tonsils, and lingual tonsils. The adenoid is centrally situated in the nasopharynx, attached to the junction of the roof and posterior wall, lying posterosuperior to the posterior nasal apertures (choanae) and adjacent to lymphoid tissue surrounding the nasopharyngeal openings of the eustachian tubes.[1] Owing to its strategic anatomical position, the adenoid plays a crucial role in mucosal immune defence during early childhood.[2]

The adenoid was first anatomically described in 1661 by Conrad Victor Schneider. Subsequently, in 1868, Wilhelm Meyer introduced the term "adenoid vegetations" and described them as soft, tumour-like masses occupying the nasopharyngeal space above the soft tissue palate.[3] Meyer was also the first to establish the association between adenoid enlargement and clinical features such as nasal obstruction, mouth breathing, snoring, and hearing impairment, and he advocated surgical removal as a treatment modality.[4] Adenoid hypertrophy (AH) refers to the pathological enlargement of adenoid tissue and may occur with or without associated acute or chronic infection.[5] Radiologically, the normal adenoid thickness is approximately 6.2 mm, whereas hypertrophied adenoids measure around 11.6 mm. An adenoid size exceeding 12 mm is considered abnormal in children aged 2–10 years.[6] Adenoid hypertrophy is the most common cause of upper airway obstruction in children and adolescents. Although it represents a physiological response to increased immunological activity in early life, persistent enlargement may result in significant morbidity. Clinical manifestations include mouth breathing, nasal obstruction, recurrent upper respiratory tract infections, speech disturbances, asthma, and obstructive sleep apnea. Chronic upper airway obstruction may further lead to altered craniofacial growth, sleep disturbances, behavioural problems, impaired cognitive development, and reduced scholastic performance.[7]

A recent systematic review and meta-analysis reported the prevalence of adenoid hypertrophy among children and adolescents to be approximately 34.46%, emphasizing its substantial public health burden.[7] Conventional management of adenoid hypertrophy includes antibiotics and intranasal corticosteroids, while surgical adenoidectomy is recommended in severe or refractory cases. However, surgical intervention is associated with potential complications, including haemorrhage, infection, recurrence, anaesthetic risks, and adverse effects on quality of life. [8,9,10] Homoeopathy adopts a holistic and individualized approach intended to stimulating the body's self-regulatory mechanisms and restoring constitutional balance. Preliminary clinical observations and published case reports suggest that individualized homoeopathic treatment may help reduce symptoms of adenoid hypertrophy, improve nasal airflow, and decrease the frequency of recurrent infections, and potentially prevent the need for surgical intervention. Nevertheless, despite encouraging outcomes reported in isolated case studies, high-quality scientific evidence remains limited. An article titled "Evidence-Based Study of Enlarged Adenoid Treated with Homoeopathic Medicine: A Case Report" draws attention to the need for subsequent observational studies and well-designed randomized controlled trials to establish the efficacy of homoeopathy in the management of enlarged adenoids.[11]

Etiopathogenesis

Adenoid hypertrophy is a multifactorial disorder resulting from persistent antigenic stimulation and chronic inflammation of adenoid tissue. While adenoidal enlargement is a normal physiological process during childhood, infectious, allergic, and environmental elements may contribute to excessive lymphoid hyperplasia, leading to pathological enlargement and associated clinical manifestations. The principal factors involved in its etiopathogenesis are outlined below.

Physiological Factors:
Physiological enlargement of the adenoid is a normal developmental phenomenon that occurs during childhood as part of the maturation of the immune system. Continuous exposure to environmental antigens stimulates lymphoid tissue growth, and the adenoid typically reaches its maximum size between 5 and 7 years of age. This enlargement is generally transient and undergoes gradual involution after puberty. However, prolonged or excessive antigenic stimulation may contribute to pathological hypertrophy. [5,12]

Infectious Factors:
Recurrent and persistent upper respiratory tract infections are important contributors to adenoid hypertrophy. Both bacterial and viral pathogens can trigger chronic inflammation and sustained immune activation in the adenoid tissue, leading to lymphoid hyperplasia and tissue enlargement. Chronic infection may manifest clinically as nasal obstruction, mouth breathing, hyponasal speech, and eustachian tube dysfunction, thereby increasing the risk of middle-ear disorders and recurrent respiratory illnesses. [5,12]

Allergic Factors:
Allergic diseases, particularly allergic rhinitis, play a significant role in the development of adenoid hypertrophy. Persistent exposure to allergens induces IgE-mediated inflammatory responses that promote mucosal oedema and lymphoid tissue proliferation. As a result, children with allergic rhinitis are more likely to develop enlarged adenoids and experience more severe symptoms than their non-allergic counterparts. [13,14]

Other Contributing Factors:
Additional factors such as gastroesophageal reflux disease (GERD) and passive exposure to tobacco smoke have been associated with adenoid hypertrophy. Reflux of gastric contents into the nasopharynx can cause chronic irritation and inflammation of the adenoid tissue, while second-hand smoke impairs mucociliary function and perpetuates inflammatory changes. Both factors may cause persistent adenoid enlargement and its associated clinical manifestations. [15,16]

Clinical Manifestations
The clinical manifestations of adenoid hypertrophy are determined not only by the absolute size of the adenoidal tissue but also by its relationship to the available nasopharyngeal space. Hypertrophied and infected adenoids may produce a wide spectrum of nasal, aural, and general systemic symptoms.[17]

Nasal Symptoms
- Nasal Obstruction and Congestion: These are the commonest symptoms. This leads to mouth breathing and snoring.
- Nasal Discharge: It is partly due to choanal obstruction, as normal nasal secretions cannot drain into the nasopharynx, and partly due to associated rhinitis and recurrent pharyngitis.
- Sinusitis: Chronic maxillary sinusitis is commonly associated with adenoids. It is due to persistent nasal discharge and infection.
- Epistaxis: When adenoids are acutely inflamed, epistaxis can occur with nose blowing.
- Voice Change: Toneless, with nasal quality lost due to nasal obstruction.

Tubal Symptoms
- Tubal Obstruction: An adenoid mass blocks the Eustachian tube, leading to a retracted tympanic membrane and conductive hearing loss.
- Recurrent attacks of acute otitis media may occur due to the spread of infection via the eustachian tube.
- Serous Otitis Media:The waxing and warning signs of adenoids cause intermittent eustachian tube obstruction with intermittent hearing loss.

General Symptoms

- Adenoid Facies: In long-standing cases, children may develop a characteristic facial appearance known as "adenoid facies." This is characterised by a dull facial expression, pinched nostrils, persistent mouth opening, a narrow maxillary arch, a shortened or retracted upper lip, and protruding upper incisors. These features result from chronic nasal obstruction and habitual mouth breathing associated with adenoid hypertrophy.
- Difficult breathing, obstructive sleep apnoea syndrome.

Diagnosis of Adenoid Hypertrophy

A thorough history and detailed physical examination are often sufficient to diagnose adenoid hypertrophy. Physical examination of children with adenoid hypertrophy commonly reveals habitual mouth breathing, parted lips, and a dull facial expression. In chronic cases, characteristic features of adenoid facies, including an open-mouth posture, elongated face, high-arched palate, dental malocclusion, and facial muscle hypotonia, may be present. Anterior rhinoscopy may demonstrate nasal cavity narrowing, mucosal congestion, and mucopurulent discharge, while pale, oedematous mucosa may suggest associated allergic rhinitis. Oral examination may show persistent mouth breathing, a high-arched palate, dental abnormalities, and postnasal drip. Enlarged, mobile, non-tender upper deep cervical lymph nodes may be palpable due to chronic infection. Although the adenoid is not usually visible on routine examination, it may occasionally be observed behind the soft palate, and digital palpation can reveal a soft, lobulated nasopharyngeal mass consistent with adenoid tissue.[18] The diagnosis of adenoid hypertrophy is primarily based on radiological and endoscopic evaluation. Lateral X-ray of the nasopharynx is a simple, cost-effective screening tool that demonstrates adenoidal enlargement and the degree of nasopharyngeal airway obstruction. Flexible nasopharyngoscopy is considered the gold standard, allowing direct visualization of the adenoids and precise evaluation of choanal obstruction. Computed tomography (CT) and magnetic resonance imaging (MRI) provide detailed anatomical evaluation and are generally reserved for selected cases, as they are not routinely indicated in the assessment of adenoid hypertrophy.[19]

Generalized Management of Adenoid Hypertrophy

The management of adenoid hypertrophy aims to relieve upper airway obstruction, prevent complications such as otitis media with effusion, and control recurrent nasopharyngeal infections.[20] Initial treatment is primarily conservative and includes intranasal corticosteroids, which have been shown to improve nasal airflow and reduce adenoid size. Supportive measures such as saline nasal irrigation, management of associated allergic rhinitis, and appropriate antibiotic use for acute bacterial infections may also be beneficial. Observation and periodic follow-up are appropriate for children with mild symptoms and no significant functional impairment. [21,22,23] Surgical intervention in the form of adenoidectomy is reserved for patients who do not respond adequately to medical management or who present with significant nasal obstruction, obstructive sleep apnea, recurrent adenoiditis, chronic otitis media with effusion, or chronic rhinosinusitis. The decision for surgery should be based on a comprehensive clinical evaluation and appropriate diagnostic investigations. [24,25]

Homoeopathic Management of Adenoid Hypertrophy

According to the Hahnemannian concept of disease, so-called local diseases are not simply confined to a particular part of the body but are expressions of a general morbid disturbance of the vital force. Samuel Hahnemann classified local diseases into two broad categories.[26] 1. Local Diseases of Internal Origin (Pseudo-local or Pseudo-surgical Diseases) 2. Local Diseases of External Origin (True Surgical Diseases) [26] Local diseases of internal origin do not arise independently at the affected part but originate from an internal derangement of the vital force, of which the local affection is only a manifestation. Although such diseases appear to be confined to a particular organ or tissue, they represent a general dynamic disturbance of the organism as a whole. As stated by Samuel Hahnemann in the Organon of Medicine:

Aphorism 185: "Those diseases which are called local do not arise from local causes, but depend upon an internal disease, of which the local affection is only a manifestation."[26] **Aphorism 186** further clarifies: "The local symptoms disappear only when the internal disease is cured."

In Aphorism 186, he distinctly states: "Those local maladies which arise solely from external causes, such as injuries, wounds, fractures, dislocations, burns, etc., must be treated by surgical or mechanical aid." According to Hahnemann, surgical intervention is essential in local diseases arising from definite external causes; however, when no external impediment to cure is present, the appropriate and rational approach is constitutional Homoeopathic treatment.[26] In Hahnemann's Lesser Writings, he also condemns unnecessary surgery, calling it "mutilation" if carried out without addressing the internal disease.[27] Some of the medicines which are indicated in cases of Adenoid hypertrophy are as follows:[28,29,30,31]

Agraphis nutans
Adenoids, throat deafness. Catarrhal conditions, obstruction of nostrils; Throat and ear troubles with tendency to free discharge from mucous membranes. Clarke of London regarded this remedy as a leading one in cases of adenoids. It was first used by Cooper in 1892. Deafness and deaf-mutism, breathes with mouth open. It is essentially a catarrhal remedy and acts specially on the glands connected with the nasal cavity, and its use generally avoids adenoid surgeon.

Calcarea iodata
Enlarged adenoids, tonsils filled with little crypts and pockets. In cases which are febrile in nature. Flabby children subjects to cold, discharges profuse and yellow, profuse sweat.

Sanguinarinum nitricum
Nose feels obstructed, enlarged turbinates at beginning of hypertrophic process. Post-nasal secretions adherent to nasopharynx, swallowing difficult. Secretion scanty, tendency to dryness.

Baryta carbonica:
Awakes with dry mouth. Catarrh of posterior nares, with frequent epistaxis. Reverberation on blowing nose. Especially in children who have recurring attacks of acute tonsilitis. Tendency to suppuration of glands. Delayed physical and mental development. Chilly patient, greatly sensitive to cold, have offensive foot sweat, timid, lack of self-confidence, Thinking of complaints makes them worse, better in open air

Calcarea carbonica: Scrofulous constitutions who take cold easily with increased mucoid secretions. Stoppage of nose, with fetid, yellow discharge. Swelling of tonsils and submaxillary glands. Chilly patient, takes cold easily, fat, fair, flabby, distended abdomen, pale, weak, easily tired, head sweat profusely while sleeping, sour smelling discharges, longing for fresh air, desire for eggs and indigestible things, sweets, aversion to meat and milk, fearful, slow, sluggish, feels better when constipated.

Calcarea phosphorica: Adenoid growth. Defective hearing. Suffocative cough; better lying down. Highly Recommended by Cooper, Clifton and may others as a most effective remedy in adenoid vegetations. It corresponds to dyscrasia, which permits adenoids growths or tonsillar enlargement. Anaemic children who are peevish, delicate, tall, thin with dirty brownish skin, have cold extremities and feeble digestion, all the symptoms are worse from any change of weather, craving for salted or smoked meat.

Iodium
Adenoid vegetations. Nose stopped up; larynx feels constricted. Eustachian deafness. Rapid metabolism, loss of flesh with great appetite, great debility, feels always too hot, slightest efforts induces perspiration, better after eating.

Tuberculinum
Persistent, offensive otorrhoea. Perforation in membrane tympani, with ragged edges. Sensation of suffocation, even with plenty of fresh air. Enlarged tonsils. Takes cold very easily, tall, lean, thin, narrow-chested, active and precocious mentally but weak physically, emaciated with good appetite, obstinate and disobedient children, irritable,

desire to use foul language. Adenoids are greatly benefited and often times cured by a weakly dose of Tuberculinum or preferably Bacillinum.

Medorrhinum

Coldness of tip. Posterior nares obstructed. Chronic nasal and pharyngeal catarrhs. Can inhale but cannot exhale. Nose dirty, tonsils enlarged, thick yellow mucus from nostrils; lips thickened from mouth breathing. Hot patients, takes cold easily, chronic catarrhal conditions in children, children pale, dwarfed and stunted in growth, mentally dull and weak, difficult concentration, desire salt, sweets, ice, acids, oranges, sour things.

Kalium iodatum

Nasal catarrh, involving frontal sinuses. Stuffiness and dryness of nose, without discharge. Profuse, cool, greenish, non-irritating discharges. Accumulation of very tenacious mucus in nostrils. Offensive odour from mouth. Glandular swellings or atrophy, diffused sensitiveness of glands, discharges are copious, watery, acrid, salty, thick, green or foul, weakness, emaciation.

Hydrastis Canadensis

It is the First remedy to be tried, when the mucous membrane is yellow and there is excessive enlargement. Dr. Lambrechts, of Antwerp, uses a tampon of Hydrastis and glycerine 1:6, introduced deep into each nostril, having child make inspirations. lymphoid hypertrophy, mucous yellowish in colour, post-nasal catarrh.

Cistus Canadensis

In scrofulous or arthritic individuals who have adenoid vegetations. There is extreme sensitiveness to cold air, this is characteristic. Sensation of heat and dryness in the throat so intense that the patient must drink to relieve. Cold air inhaled causes distress in the throat, the 6th potency seems to succeed the best. Cistus has a special affinity for the nasopharynx.

CONCLUSION

Adenoid hypertrophy is a common paediatric disorder that frequently leads to upper airway obstruction and associated functional impairments, often prompting consideration of surgical intervention. Homoeopathy views this condition as a manifestation of an underlying constitutional imbalance rather than merely a localized pathological process. Through individualized remedy selection based on the totality of symptoms, homoeopathic treatment aims to stimulate the body's self-regulatory mechanisms and restore overall health. Clinical observations and published case reports suggest that homoeopathy may play a beneficial role in reducing symptoms, improving quality of life, and potentially lessening the need for surgical intervention in selected cases. Nevertheless, further well-designed clinical studies are essential to strengthen the evidence base and establish the role of homoeopathy in the management of adenoid hypertrophy as a pseudo-surgical condition.

ABSTRACT

Surgical orthodontics or orthodontic-orthognathic treatment is a multidisciplinary treatment used for the management of severe dentofacial deformities not correctable by conventional orthodontic treatment alone. This approach re-establishes skeletal harmony, functional occlusion and facial esthetics, by combining the orthodontic therapy with the orthognathic surgery. Advancements in diagnostic imaging, 3-dimensional treatment planning, virtual surgical simulation, and rigid fixation techniques in the past several decades have greatly enhanced the accuracy and predictability of treatment. Success depends on correct diagnosis, judicious treatment planning, adequate presurgical orthodontic preparation, precise surgical execution and judicious postsurgical orthodontic finishing. A review of current concepts of surgical orthodontics including evolution, indications, diagnostic evaluation, cephalometric assessment, treatment sequence, stability, complications and recent advances in technology is presented.

Keywords: Surgical orthodontics, orthognathic surgery, dentofacial deformity, presurgical orthodontics, cephalometric analysis, orthognathic treatment.

INTRODUCTION

The scope of surgical orthodontics has increased considerably over the years. The early orthodontic treatment focused mainly on the correction of dental malpositions and functional occlusion. The treatment objectives have now evolved from dental alignment to include a better understanding of facial esthetics, skeletal harmony and patient

quality of life [1]. Today the emphasis is on achieving a balanced relationship between the facial skeleton, dentition and soft tissues in the restoration of function and aesthetics. Surgical orthodontics is a multidisciplinary approach that combines orthodontic treatment with orthognathic surgery to manage dentofacial deformities that cannot be corrected by orthodontics alone. It is indicated for patients with significant skeletal discrepancies involving the maxilla, mandible, or both jaws in the sagittal, vertical, or transverse planes, where surgical correction is necessary to achieve optimal functional and esthetic outcomes. The modern era of orthognathic surgery began with the pioneering work of Trauner and Obwegeser in 1957, who presented new techniques that revolutionized the treatment of mandibular deformities. Bell, Epker, Wolford, and other investigators have improved maxillary surgery, Le Fort osteotomies, and fixation techniques, making orthognathic surgery safer and more predictable [2]. Advancements in surgical techniques, imaging technologies, and treatment planning have made surgical orthodontics a reliable treatment modality that enhances facial esthetics, functional occlusion, airway dimensions, and overall patient well-being today.

Indications for Surgical Orthodontic Treatment

Skeletal discrepancies that are not amenable to adequate correction with conventional orthodontic treatment or growth modification alone are indications for surgical orthodontics. The decision to perform surgical treatment depends on several factors: the severity of the skeletal deformity, the degree of functional impairment, the patient's esthetic concerns and his expectations from the results of treatment [3]. A complete clinical assessment and a personalized treatment plan are important to determine whether a combined orthodontic-surgical approach is the best option.

Common indications include:

Sagittal discrepancies

- Skeletal Class II due to mandibular deficiency
- Skeletal Class III due to mandibular prognathism or maxillary deficiency
- Severe maxillary protrusion/retrusion and excessive overjet.

Vertical discrepancies

- Anterior open bite
- Skeletal deep bite
- Vertical maxillary excess or deficiency
- Long-face syndrome

Transverse discrepancies

- Maxillary constriction
- Skeletal crossbite
- Facial asymmetry
- Occlusal cant

Craniofacial deformities

- Cleft lip and palate
- Hemifacial microsomia
- Treacher Collins syndrome
- Pierre Robin sequence
- Other craniofacial syndromes

Proffit's Envelope of Discrepancy continues to be a vital guide to the decision of when skeletal discrepancies require orthognathic surgery and not orthodontics alone.

Objectives of Orthognathic Treatment [4]

The objectives of orthognathic treatment are:

•Function – Achieve normal masticatory, speech, respiratory, swallowing, and temporomandibular joint function.
•Esthetics – Enhance facial harmony, profile, smile esthetics, and adjacent soft tissue balance.
•Stability – Provide predictable long term stability with proper diagnosis, judicious orthodontic preparation, precise surgical correction and favorable soft tissue adaptation.

Diagnosis and Treatment Planning

Careful diagnosis and treatment planning are critical to success in surgical orthodontic treatment. Orthodontists and oral and maxillofacial surgeons should approach cases from a team perspective to optimize functional and esthetic results. Restorative and periodontal specialists should be consulted when necessary.

Patient evaluation

A comprehensive patient evaluation should include the chief complaint, medical and dental history, periodontal status, previous orthodontic treatment, and patient psychological acceptance of treatment. Systemic problems that may negatively impact treatment results should be addressed and patient expectations clarified.

Clinical Facial Analysis

Clinical facial analysis should be a part of the treatment planning records and should include symmetry of the face, facial midlines, facial proportions, lip relationships (competence/incompetence), smile characteristics (relations-ships, lip breakup, gingival show), facial profile convexity, jaw prominence, chin vertical and horizontal positions, and overall soft tissue balance.[5,6] Because the success of orthognathic surgery is determined primarily by the improvement of facial appearance, diligent soft tissue analysis is essential.

Temporomandibular joint assessment

The temporomandibular joint should be assessed in all orthognathic patients. Joint sounds, range of mandibular movement, functional deviation, pain, and muscle tenderness should be recorded. If the patient has an underlying disease process such as internal derangement, degenerative joint disease, condylar resorption, or inflammatory disease process, it should be noted and treated prior to orthognathic surgery. [7]

Radiographic and Imaging Assessment

Radiographic evaluation plays a vital role in the diagnosis and treatment planning of surgical orthodontic patients. Routine investigations include lateral and posteroanterior cephalograms, panoramic radiographs, and periapical radiographs to assess skeletal and dental relationships. Cone Beam Computed Tomography (CBCT) [8] has further enhanced diagnosis by providing three-dimensional visualization of the craniofacial skeleton, airway, temporomandibular joints (TMJs), root morphology, and facial asymmetry, thereby improving the accuracy of diagnosis and virtual surgical planning.

Cephalometric Evaluation

Cephalometric analysis remains an indispensable component of orthognathic treatment planning, providing valuable information about the underlying skeletal relationships and growth pattern.

- **Sagittal analysis:** Measurements such as SNA, SNB, ANB, Wits appraisal, and facial convexity angle are used to assess the anteroposterior relationship between the maxilla and mandible.
- **Vertical analysis:** Parameters including lower anterior facial height, mandibular plane angle, Jarabak ratio, Sassouni analysis, McNamara analysis, and COGS analysis help evaluate vertical facial proportions and skeletal growth patterns. [9]
- **Transverse analysis**: Grummons[10] and Ricketts posteroanterior analyses [11] are useful for assessing facial asymmetry, transverse skeletal discrepancies, midline deviations, occlusal cant, and maxillary constriction.

Presurgical Orthodontics

Presurgical orthodontics plays a crucial role in orthognathic treatment. It prepares the teeth and supporting structures for surgical correction. The main goal is to position the teeth properly over their underlying bones. This process helps eliminate dentoalveolar compensations and creates a suitable dental relationship for accurate surgical jaw repositioning. Unlike traditional orthodontic treatment, which often hides skeletal issues, presurgical orthodontics aims to reveal the actual skeletal deformity. This approach allows for complete surgical corrections. [12]

Objectives of Presurgical Orthodontics

The key goals of presurgical orthodontic treatment are to:

- Align and level the dental arches.
- Correct tooth rotations and fix arch length discrepancies.
- Set the ideal angle and torque for incisors.
- Remove dentoalveolar compensations.
- Coordinate the shapes of the upper and lower arches.
- Achieve the best intercuspation after surgery.
- Use stable, full-dimension surgical archwires before the operation.

Orthodontic Decompensation

Dental compensations may be counterproductive to the underlying skeletal discrepancies, and may be responsible for maintaining a functional occlusion in the presence of the deformity. These compensations need to be removed before orthognathic surgery, to allow accurate jaw repositioning. If orthodontic decompensation is corrected, the true skeletal discrepancy will be uncovered and total correction of this discrepancy can be achieved with surgery, providing a better functional and esthetic correction. [12]

Sagittal Decompensation

Typically, the mandibular incisors are proclined and the maxillary incisors are retroclined, as an adaptation in patients with skeletal Class II malocclusion. In contrast, skeletal Class III malocclusion is usually associated with retroclined mandibular incisors and proclined maxillary incisors. The goal of presurgical orthodontics is to eliminate these compensations by moving the incisors into their optimum position in relation to the basal bone and revealing the true skeletal discrepancy for the correct surgical correction. [13]

Vertical Decompensation

Dentoalveolar compensations may be present as a vertical pattern in patients with a deep bite or anterior open bite, and may mask any underlying skeletal imbalance. The primary goal of presurgical orthodontics is to remove these compensations mindfully along with the lower anterior facial height, incisor display and overall facial proportions, so that the planned surgical movements result in optimal function and esthetic smile.

Transverse Decompensation

Transverse decompensation focuses on correcting the dental compensations associated with skeletal crossbites and transverse jaw discrepancies. Teeth are aligned over their supporting alveolar bone to establish proper maxillary and mandibular arch coordination, thereby facilitating accurate correction of the transverse skeletal deformity during surgery. [14]

Presurgical Considerations in Deep-Bite Cases

Management of deep-bite patients requires careful evaluation of the lower anterior facial height and the curve of Spee. In patients with a reduced lower facial height, complete leveling of the curve of Spee before surgery may not be desirable. Preserving the curve allows mandibular advancement surgery to increase lower facial height and improve facial balance. Final leveling of the occlusion can then be completed during the postsurgical orthodontic phase, contributing to improved occlusal stability and facial esthetics. [15]

Presurgical Considerations in Open-Bite Cases

Patients with anterior open bite generally require extensive orthodontic decompensation before surgery to expose the underlying skeletal discrepancy. In skeletal Class III open-bite cases, the mandibular incisors are proclined and the maxillary incisors are uprighted to establish an adequate reverse overjet. Mandibular incisors are uprighted in skeletal Class II open bite patients, and maxillary incisors are properly compensated, although this may lead to an increase in overjet before surgery. This decompensation is crucial to obtain correct skeletal correction and postoperative occlusion stability. [16]

Arch Coordination

Proper coordination of the maxillary and mandibular arches is a fundamental requirement for successful orthognathic surgery. Well-coordinated arches facilitate accurate jaw repositioning and contribute to optimal postoperative intercuspation.

Arch Width Coordination

The transverse dimensions of the maxillary and mandibular arches should be compatible in the planned postsurgical position. Severe transverse skeletal discrepancies may require surgically assisted maxillary expansion or segmental osteotomies, whereas minor transverse discrepancies can often be corrected through conventional orthodontic treatment.

Arch Form Coordination

Presurgical orthodontics should also establish compatible arch forms to ensure stable postoperative occlusion. Skeletal Class II malocclusions commonly present with tapered maxillary arches, while skeletal Class III malocclusions are frequently associated with tapered mandibular arches. Appropriate arch coordination promotes ideal intercuspation and enhances long-term treatment stability. [17]

Appliance Selection and Surgical Preparation

Preadjusted edgewise appliances are generally preferred during presurgical orthodontics because they provide excellent control of tooth movement and sufficient stability during surgery. Before the surgical procedure, full-dimension rectangular stainless-steel archwires [18] are placed to stabilize the dentition and facilitate accurate jaw positioning during orthognathic surgery.

Common stabilizing archwires include

- 0.017 × 0.025-inch stainless steel in 0.018-inch slot appliances.
- 0.021 × 0.025-inch stainless steel or TMA in 0.022-inch slot appliances.
- 0.019 × 0.025-inch stainless steel in selected 0.022-inch systems.

Kobayashi or surgical hooks are incorporated into the archwires to facilitate intermaxillary fixation.

Presurgical Records and Final Planning

Once presurgical orthodontic treatment has been completed, comprehensive pretreatment records are obtained to finalize the surgical plan. These records typically include lateral and posteroanterior cephalograms, panoramic radiographs, study casts, and intraoral and extraoral photographs. Together, they are used for cephalometric prediction tracing, model surgery, virtual surgical planning, and the fabrication of surgical splints, ensuring accurate transfer of the treatment plan to the operating room.

Clinical Significance

Presurgical orthodontics forms the cornerstone of successful orthognathic treatment. Precise surgical correction is founded on careful alignment of the dentition, elimination of dental compensations, coordination of the dental arches and stabilisation of the occlusion. This systematic preparation not only enhances facial esthetics and functional occlusion but also is a critical step towards achieving long-term stability and predictable treatment outcomes.

Orthognathic Surgical Procedures

The goal of orthognathic surgery is to move one or more of the maxilla, mandible, chin or other anatomical structures (through surgery) to provide skeletal stability, establish a functional and aesthetically appropriate relationship between the upper and lower teeth, and optimize the esthetics and function of the overall system. The exact procedure to be used will depend on the type of dentofacial deformity that is to be corrected and the treatment objectives that are defined during the planning phase of treatment (before a final treatment plan is decided upon).

Maxillary Surgery

Le Fort I Osteotomy

The Le Fort I osteotomy is the most commonly performed maxillary procedure and allows movement of the maxilla in all three planes of space. [19]

Applications include:

- Maxillary advancement or setback
- Superior or inferior repositioning
- Correction of asymmetry
- Closure of anterior open bite
- Segmental expansion

Segmental Maxillary Osteotomy

Segmental osteotomies are used to correct arch width discrepancies, open bites, dental protrusion, and localized transverse deficiencies.

Mandibular Surgery Bilateral Sagittal Split Osteotomy (BSSO) [20] BSSO is the most frequently used procedure in the mandible, and is indicated for advancement, setback and correction of asymmetry. It promotes predictable healing, rigid fixation and good stability. Vertical Ramus Osteotomy [21] This procedure is mainly used for mandibular setback in selected patients but usually requires prolonged intermaxillary fixation. Genioplasty [22] Genioplasty is commonly performed to improve facial balance and includes advancement, reduction, vertical augmentation or reduction, and correction of chin asymmetry. Bimaxillary Surgery [23] For severe dentofacial deformities, surgery may be necessary on both jaws at the same time. It offers better facial harmony, corrected occlusion, better airway results and long-term stability over single jaw procedures.

Surgical Prediction and Treatment Planning

Careful surgical prediction and treatment planning is mandatory for accurate and predictable results in orthognathic surgery. Prediction tracing assists the clinician in predicting the changes in the facial profile, evaluating the expected occlusal relationship, determining the need for dental extractions, and assessing the need for adjunctive procedures like genioplasty. It also allows the orthodontist to communicate with the surgeon in the treatment planning stage. While traditional cephalometric prediction tracing continues to be a useful diagnostic tool, it has been largely replaced by computer-assisted simulations, three-dimensional virtual surgical planning, and digital treatment workflows that are more accurate, improve surgical precision, and improve the predictability of overall treatment.[24]

Postsurgical Orthodontics [25]

Following surgery, orthodontic treatment is required to refine the occlusion and ensure long-term stability.

Objectives

- Settling of occlusion
- Closure of residual spaces
- Refinement of intercuspation
- Correction of minor tooth discrepancies
- Establishment of ideal overjet and overbite

Postsurgical orthodontics is generally shorter than presurgical treatment because the major skeletal correction has already been achieved.

Retention

Retention protocols may include:

- Fixed lingual retainers
- Removable retainers
- Vacuum-formed retainers

Retention is particularly important in patients with severe skeletal discrepancies and those treated for open bite deformities. [26]

Stability and Relapse [27]

Long-term stability is one of the most important determinants of treatment success.

Factors Influencing Stability

Surgical Factors

- Magnitude of skeletal movement
- Direction of movement
- Fixation technique
- Surgical accuracy

Orthodontic Factors

- Adequate decompensation
- Proper arch coordination
- Occlusal finishing

Biological Factors

- Muscular adaptation
- Soft tissue tension
- Growth potential
- Temporomandibular joint health

Stability of Common Procedures

Highly stable procedures:

- Maxillary impaction
- Mandibular advancement (moderate movements)
- Genioplasty

Moderately stable procedures:

- Maxillary advancement
- Bimaxillary surgery

Less stable procedures:

- Mandibular setback
- Vertical maxillary elongation
- Open bite correction involving extrusion

Complications of Orthognathic Surgery

Orthognathic surgery is a well-established and predictable procedure with a high success rate. However, as any major surgical intervention, it is associated with the risk of complications in the intraoperative, early postoperative and late postoperative periods. Careful patient selection, meticulous surgical technique and appropriate postoperative care are important in minimizing these risks. Intraoperative complications may include excessive bleeding, adverse fractures, damage to the inferior alveolar or other sensory nerve, and inadvertent trauma to

adjacent teeth or surrounding anatomical structures. Good preoperative planning and accurate surgical technique contribute to reduce the incidence of these complications. [28]

Early post-operative complications include infection, facial oedema, haematoma formation, temporary airway compromise and post-operative malocclusion. Most of these problems are amenable to appropriate medications, supportive care and close clinical follow-up during the healing phase.

Late postoperative complications include skeletal relapse, persistent sensory disturbances, temporomandibular joint (TMJ) dysfunction, condylar resorption, and hardware-related complications such as loosening or failure of fixation plates and screws. Regular postoperative monitoring, timely intervention when necessary, and long-term follow-up are necessary to maintain treatment stability and achieve favorable functional and esthetic outcomes. [29]

Recent Advances in Surgical Orthodontics

Technological innovations continue to transform orthognathic treatment.

Three-Dimensional Imaging [30]

CBCT provides accurate assessment of:

- Skeletal morphology
- Airway volume
- Facial asymmetry
- Root positions

Virtual Surgical Planning [32]

Digital workflows enable:

- Precise osteotomy planning
- Surgical simulations
- CAD/CAM splints
- Patient-specific fixation systems

Skeletal Anchorage Systems [33]

Temporary anchorage devices (TADs) have expanded the orthodontic envelope of discrepancy and reduced the need for surgery in selected patients.

Artificial Intelligencev [34]

Emerging applications include:

- Automated cephalometric landmark identification
- Surgical outcome prediction
- Treatment planning assistance
- Facial simulation models

Airway-Focused Treatment Planning [35]

The correlation between the jaw position and airway dimensions is increasingly demonstrated. In addition to the esthetic and occlusal benefits, orthognathic surgery is increasingly being used for the improvement of respiratory function and obstructive sleep apnea.

Future Perspectives

Digital technology and bio-materials are progressing at a rapid pace, shaping the future of surgical orthodontics. New innovations are expected to improve all aspects of treatment from diagnosis and planning to surgical execution and long term follow up. Likely future developments include artificial intelligence assisted diagnosis, fully digital treatment workflows, augmented reality guided surgical navigation, personalized treatment planning, advanced biomaterials with improved fixation systems and more accurate prediction of soft tissue changes following surgery.

Further development of these technologies should further increase the accuracy of treatment, improve the efficiency of surgery, reduce the morbidity to the patient and ultimately predict better function and esthetic results with greater patient satisfaction. [36]

CONCLUSION

Surgical orthodontics is indicated for severe dentofacial deformities which cannot be corrected by orthodontic treatment alone. Successful outcomes depend on accurate diagnosis, comprehensive treatment planning, coordinated presurgical orthodontics, precise surgery, and meticulous postsurgical finishing. The precision and predictability of treatment have been greatly improved by recent advances in CBCT imaging, virtual surgical planning, skeletal anchorage, and digital workflows. The objective of modern orthognathic treatment is to improve occlusion, facial aesthetics, function, airway health, and quality of life. Continued technology will continue to make surgical orthodontic care more precise, more personalized and more successful in the long term.

ABSTRACT

Loops in orthodontics constitute one of the most biomechanically sophisticated and clinically versatile tools available to the orthodontist. Rooted in the principles of frictionless mechanics, loop springs deliver controlled, predictable force systems characterised by well-defined moment-to-force (M/F) ratios that offer superior command over tooth movement type compared to conventional sliding mechanics. This review addresses the fundamental biomechanics governing loop design, including the principles of centre of resistance, centre of rotation, M/F ratio, load-deflection rate (LDR), springiness, pre activation bends, and anchorage control. Basic designs including the vertical loop, horizontal loop, omega loop, helical loop, Bull loop, and resilient vertical loop are examined for their historical origin, wire specifications, and biomechanical properties. Advanced designs like the T-loop, asymmetric T-loop, Opus loop, PG retraction spring, K-SIR arch, mushroom loop, MEAW, snail loop, and ballista spring are evaluated in depth. Clinical applications, Complications, risk management, and contemporary directions including CAD/CAM loop fabrication and skeletal anchorage integration are discussed, together with a critical appraisal of friction versus frictionless mechanics.

Keywords: Loops in orthodontics, frictionless mechanics, T-loop, moment-to-force ratio, space closure, beta-titanium, load-deflection rate, MEAW

INTRODUCTION

Space closure is one of the most biomechanically difficult stages of orthodontic treatment. While sliding mechanics dominated clinical practice for decades, its basic requirement on bracket archwire contact creates resistance to movement that includes torque expression, force prediction, and anchor control through friction, binding and notching. These limitations forced a fundamental revaluation of the management of extraction areas, which ultimately led to the creation and improvement of frictionless loop mechanics as a more regulated option. By applying force through specially designed springs, loop based mechanics completely eliminates frictional losses. This enables the clinician to purpose engineered springs, allowing the clinician to precisely control the moment to force ratio that determines whether a tooth tips, translates, or undergoes root movement. The development of beta-titanium alloy, which offers better spring back and lower load- deflection rates than stainless steel, which completely expanded the therapeutic utility of loops. Loop geometry has evolved over time to handle the four dimensions of force controli.e distribution, direction ,amplitude, and duration ranging from early helical and tear drop loops to complex designs like the T-loop, Opus loop, and K-SIR arch. In current modern and orthodontics, a variety of loop designs are used, analysing their optimal size, activation protocols, and clinical uses.[1]

Basic Principles of Orthodontic Tooth Movement

In simple terms, orthodontic tooth movement is a physiological process that is started by applying precise mechanical stresses to the teeth. When a tooth is subjected to force, the periodontal ligament(PDL) and alveolar bone experience a pressure-tension phenomena that results in osteoclastic resorption on the pressure side and osteoblastic opposition on the tension side. The histology foundation of orthodontic tooth movement is this linked cellular response.Hooke's Law, which states that deflection is proportional to the applied force within the elastic limit;Newton's Third Law, which requires equal and opposite reaction forces and requires careful anchorage planning; and the principle of equilibrium, which demands that all forces and moments in the system be taken into account in order to achieve, predictable tooth movement, are the three guiding principles of physics that support appliance design. The guiding archwire in loop mechanics is replaced by specifically designed springs, which must independently produce the proper forces, moments, and moment to force ratios.In relation to sliding mechanics, where friction between the bracket and archwire produces unexpected variation, loop mechanics delivers stable force systems with far greater precision because no force is lost due to frictional resistance at a bracket wire interface. The theoretical point at which a single force results in pure translation without any rotating component is known as the Center of Resistance (CR). This is roughly around the mid-root level for single- rooted teeth and close to the furcation for multirooted teeth. Due to the fact that orthodontic forces applied at the bracket from the CR all at once produce a force and a moment, the latter of which is equal to the force multiplied by the distance measured perpendicular between the CR and the line of force (M = F x d).[2]

The point around which a tooth really rotates under a specific force system is known as the Center of Rotation (CoR), and it moves according with the Moment-to-Force ratio (M/F ratio). The key biomechanical factor that affects the kind of tooth movement produced is this ratio:

- M/F ratio of 5:1 (Uncontrolled tipping where crown moves and root displaces in the opposite direction)
- M/F ratio of ~7:1 (Controlled tipping where crown moves and root apex remains relatively stationary)
- M/F ratio of ~10:1 (Translation or bodily movement where crown and root move equally)
- M/F ratio of >12-14:1(Root movement or torque where root apex displaces while crown remains stable)

The ability of loop mechanics to produce a certain M/F ratio through control of loop shape, preactivation bends, loop centricity, and wire material is what makes it preferable to slide mechanics.

Load-Deflection Rate, Springiness, and Wire Properties

The most important feature of any loop spring is the Load-Deflection Rate (LDR) which is the force change per unit of activation. A high acceptable working load, a wide range of action, and a low LDR are characteristics of an ideal loop. Alow LDR reduces the danger of PDL hyalinization and root resorption by assuring that light, biologically

appropriate, and continuous pressures are maintained across the whole activation range. The LDR is significantly affected by loop geometry. To lower the LDR and increase the activation range, loop height can be increased, a helical component can be added at the apex, wire length can be increased, or combination horizontal and vertical designs can be used.Finite element technique evaluations of existing designs have verified that the snail loop, which maximizes wire lenth inside a compact spiral shape, produces the lowest LDR. Equally important is wire material. The favored material for the majority of complex loop designs is beta-titanium (TMA), which was first introduced by Burstone and Goldberg in 1980. It has a modulus of elasticity that is about one-third that of stainless steel (~60–80 GPa versus ~200 GPa), offering superior springback, lower LDR, and greater resiliency. While stainless steel is still suitable for simpler loop designs requiring more rigidity despite its significant stiffness, cobalt-chromium alloys (Elgiloy) offer intermediate mechanical properties. The square of a wires yield strength divided by its modulus of elasticity determines its resilience. This explains why TMA wire has a high yield strength and a low modulus, which is the ideal combination for loop designs.[3]

Preactivation Bends and Anchorage Control

Preactivation, also known as gable bends, are angular bends inserted into a loop's legs before it is inserted. This creates a stored moment that enhances the loop's geometric moment and increases the total M/F ratio to levels that are clinically effective. Even a well designed loop may not achieve the M/F ratio required for translation in absence of adequate preactivation, leading to uncontrolled tipping, anterior flaring, and deepening of the overbite. To enable en-masse anterior retraction, gable bends of about 30° are frequently positioned at either bracket end in TMA T-loop. In loop mechanics, the varying M/F ratios provided to the anchoring and active units control anchorage. While positioning the loop closer to the posterior (beta) bracket increases the beta moment and thereby reinforces posterior anchorage by creating a distal root tipping tendency at the molar, positioning the loop off center toward the anterior (alpha) bracket increases the alpha moment and decreases the beta moment. Three categories of differential space closure are represented by this direct relationship between loop position and anchorage response: Group A (maximum anchorage), Group B (moderate anchorage), and Group C (minimum anchorage), all of which can be attained by specially adjusting loop symmetry and preactivation geometry. [4]

Classification of Loops

Orthodontic loops may be classified according to several criteria, each reflecting a distinct aspect of their design or intended function.

- **Based on Configuration**

Geometrically terms, loops can be divided into three categories: horizontal loops(like the boot loop), vertical loops, and combination designs that combine aspects of both, like the T-loop.

- **Based on Clinical Purpose**

Loops have three main functions :space closure and retraction during the mid phase of treatment,leveling and alignment during the initial phase, and multifunctional applications where a single loop design simultaneously tackles many biomechanical objectives.

- **Based on the Presence of a Helical Component**

Loops may be further classified into two categories: those containing one or more helical bulbous loop, and those without a helix, like the simple vertical loop. By adding a helix, the effective wire length within the inter-bracket span is increased, which lowers the load deflection rate and expands the activation range without raising the appliance's overall height.

- **Based on Function**

Finally, loops are differentiated by the direction of tooth movement they produce: closing loops are used in extraction space closure because they supply forces that approximate teeth, wheras opening loops create forces that move teeth apart. [5]

Since a single design may fallinto more than one category based on how it is activated and used clinically, this broader classification highlights the variety of loop mechanics.

Various Loop Designs in Orthodontics

Vertical Loop (Figure 1)

The vertical loop is the oldest loop design that was officially entered into the edgewise appliance system. It was first used in 1933 by Dr. Robert H.W. Strang, who made it from 0.016-inch stainless steel wire that was positioned perpendicular to the archwire along the occlusogingival axis and had a standard height of 6mm.It comes in two different forms: closed vertical loop, which is primarily used for space closure and the open vertical loop, which maximizes efficiency for space opening by leg compression activation. The closed version has a wider activation range than its open counterpart due to the Bauschinger effect. According to Burstone's analysis, the vertical loop yields a force deflection rate of 437 g/mm and an M/F ratio of merely 2.2 mm at 6 mm height, which is insufficient for controlled tipping or bodily translation. While helices with more than three turns provide declining biomechanical returns, increasing the loop height gradually improves the M/F ratio and adding a helical element at the apex further lowers the load deflection rate. The loop's main clinical benefit is obtained during the leveling and alignment stage, where its simple manufacturing and mild force delivery are very helpful.[6] The double vertical loop, S-loop, omega loop, horizontal loop, torquing loop, and box loop are variations of vertical loop.

Horizontal Loop (Figure 2)

According to Morris M. Stoner's 1960 description of its basic form, the horizontal loop is also known as the boot loop. When compared to the vertical loop, the loop body is positioned in the horizontal (occlusal) plane since its active legs run parallel to the archwire. Only the occlusogingival and labio-lingual planes are activated in this position; the mesiodistal plane is not included. Its main biomechanical benefit is that it reduces force in the vertical plane, allowing for instantaneous bracket engagement in teeth that are significantly intruded or extruded without using excessive force. When the double horizontal loop is placed to a single tooth, with one loop shaped to elevate and the other to depress, it works especially well for bite opening. In this manner, the tooth can be vertically repositioned or tipped under control. Although it has been described, contouring the loop against the gingival surface to produce root torque is not always successful in clinical settings.[7]

Omega Loop(Figure 3)

Morris M. Stoner first described the omega loop in 1960. It was called after Greek letter omega and was a variation of the open vertical loop. Its unique characteristic is a broadly curved, rounded apical portion made of0.016-inch or 0.018-inch stainless steel, reduces the fracture tendency that marks the acute apex of the simple vertical loop by distributing bending stress more even;y across the loops arc. Clinically, it has two main functions : it acts as a molar stop, preventing unintentional distal sliding of the archwire from the molar tube, and it acts as a physical root thrust to the final tooth in the arch.[8]

Helical Loop (Figure 4)

In order to reduce the load-deflection rate and increase the activation range, the helical loop increases wire length inside the interbracket span by including one or more coiled elements at the apex or along the legs of a vertical loop. It functions as three combined springs, including the coil and two cantilever arms. The arms of loop provide directional control, whereas wire cross-section, modulus, diameter, number of coils, and arm length affect force magnitude. Helices at the loop's reflex point typically have 1.5-2.5 turns; lateral extension coils at right-angle bends improve flexibility and keep nearby teeth from tipping.Despite being advantageous and biomechanically mild, these loops are typically heavy and prone to deformation. The bulbous helical variation is utilized for mandibular anchoring preparation and molar uprighting. It is generated at the terminal end of a 0.020 × 0.025-inch archwire to a height of 7.5 mm with a lingually coiled helix.9

Bull Loop (Squashed Vertical Loop) (Figure 5)

The Bull loop is essentially a flattened (squashed) vertical closed loop made of 0.0215 x 0.025-inch stainless steel wire. It was first introduced by Dr. Harry L. Bull in 1951 for anterior retraction in Class II, Division 1 treatment. Instead of squeezing the legs, it is actuated by opening and extending them. For the upper arch, the standard measurements are 7 mm in height with 18 mm and 22 mm of wire distal and mesial to the loop, respectively; for the lower arch, they are

5 mm in height with 20 mm distal and 28 mm mesial. One significant biomechanical benefit of using Class II elastics is that the closing loops prevent mandibular incisor proclination, which would otherwise be caused by Class Il elastic forces. In order to accommodate Class II elastic engagement. [10]

T-Loop (Figure 6)

The most researched and clinically used advanced loop in modern orthodontics, the T-loop was first presented by Dr. Charles J. Burstone in 1962 and is named for its characteristic T-shaped profile. The addition of a horizontal apical segment to the vertical legs dramatically increases wire length, elevates the M/F ratio, and enables the delivery of biologically optimal forces for anterior retraction and space closure. [11] The standard Burstone T-loop is fabricated from 0.017 × 0.025-inch TMA wire with a height of approximately 7 mm and an apical horizontal length of 10 mm.[12]The preactivated T-loops achieve approximately 10:1M/F ratios consistent with translational tooth movement. The M/F ratio is manipulated by loop centricity within the inter bracket span. Theanterior placement of loop increases the alpha moment (Group A anchorage), while posterior placement increases the beta moment (Group C mechanics).[13]Preactivation through gable bends that is typically ~ 10.5° at the alpha end and 25-35° at the beta end for Group A retraction to introduce a stored moment that supplements the geometric M/F ratio. Importantly, the T-loop is self correcting: as the tooth moves and the loop deactivates, the force decreases by 30% while the moment decreases by only ~18%, causing the M/F ratio to rise progressively and leading to a desirable shift from tipping through translation to root up righting. Trial activation before insertion is essential to stabilize the force system and confirm no permanent deformation occurs. The T-loop is used for individual canine retraction, en-masse anterior retraction, molar up righting, and space closure in Group A, B, and C anchorage mechanics. [14]

Asymmetric T-Loop: Described by James Hilger in 1992, the asymmetric T-loop is fabricated from 0.016 × 0.022-inch or 0.019 x 0.025-inch TMA with a 2 mm anterior loop, 5 mm posterior loop, a 5 mm vertical step, and an exaggerated reverse curve of Spee. [15] This deliberate geometric asymmetric loop has shorter mesial arm generating a higher alpha moment, longer distal arm generating a lower beta moment which creates the conditions for simultaneous bite opening and anterior retraction. Activation is performed by compressing the short mesial loop and opening the long distal loop, making it particularly suited to deep bite extraction cases. [16]

Tear-Drop Loop (Figure 7)

The teardrop loop, attributed to R.G. Alexander, is characterised by its broad, rounded ovoid apical configuration,which lies between the simple vertical loop and the more complex T-loop. It is available in heights from 6 to 8 mm, with the specific height selected based on desired force and activation range. Research has established that the 6 mm teardrop loop activated by 0.5 mm delivers 2.51 N which is close to the ideal 2.60 N for mandibular incisor movement while the 8mm loop activated by 1.0 mm delivers 2.77 N. Finite element analysis by Rao et al. confirmed that the teardrop loop exhibits a higher LDR than both the Opus and snail loops, limiting its activation range. Its main drawback is limited torque control; it is mostly used in physiologically impaired individuals where conservative force levels are important and in two-step retraction techniques where light canine tipping forces are needed. [17]

Opus Loop

Raymond E. Siatkowski first proposed it in 1977.The Opus loop is one of the most systematically designed orthodontic appliance in history. Siatkowski applied Castigliano's theorem from structural mechanics to derive equations relating the M/F ratio to specific loop geometry, allowing analytical rather than empirical optimization of the design. The ascending legs are inclined at 70° to the bracket plane, the apical horizontal leg measures 10 mm, and the overall dimensions are 10 mm height, 10 mm length, and 0.5 mm corner radius. The ascending legs must be no more than 1 mm apart at the apex. Fabricated from 0.016 × 0.022-inch SS, 0.018 x 0.025-inch SS, or 0.017 x 0.025-inch TMA wire, the Opus loop delivers an M/F consistently within the range of 8.0-9.1 mm without requiring any preactivation bends which has a advantage over the T-loop that simplifies clinical use and eliminates preactivation errors. [18]

Mushroom Loop (Figure 8)

Introduced by Drs. Flavio Uribe and Ravindra Nanda in 2003, the mushroom loop is a prefabricated retraction archwire system with a broad, domed apical profile resembling a mushroom cap which is fabricated from 0.017 × 0.025-inch beta-III Connecticut new TMA archwire. The loop retains its shape despite repeated activation without distortion, and the broad apical arrangement optimizes wire length without the vertical height that frequently results in gingival impingement with T-loops. To maintain a constant translational M/F ratio during each activation interval, pre-activation of the 3 mm leg separation is done anteriorly prior to insertion; reactivation is postponed until 3 mm of space closure has taken place. In Class II, Division 2 situations where careful incisor torque preservation is required, it is especially well suited for en masse retraction. [19]

Delta Loop (Keyhole Loop) (Figure 9)

The delta loop, introduced by Burstone as a compact triangular alternative, is named for its resemblance to the Greek letter delta. It is characterized by a wedgeshaped structured, which is broader at the apex that tapers toward the archwire base, results in a lower LDR than conventional vertical loops. It can be made with or without a helical element at the top; the helical version lowers the LDR even more at the expense of a little higher volume. Patients with shallow buccal vestibules, where the height of a typical T-loop or Opus loop would invade soft tissue, are its main indication. It requires exact replication of the triangular shape and is sensitive to technique. [20]

Double Keyhole Loop (DKL)

Keyhole Loop (DKL) which was first used in Roth straight wire mechanics by John Parker of Alameda, California, is made of 0.019 x 0.025-inch rectangular stainless steel archwire and comprises of two symmetrical keyhole shaped loops positioned bilaterally near the canines on each side of the arch. Each loop has a height of 7 mm; the distance between the two loops on the same side is approximately 8 mm. The combined vertical and horizontal geometry creates a champagnebottle appearance. Three prerequisites for DKL insertion are mandatory: an anterior sector free of diastema and consolidated with ligature wire; wellaligned arches with torque fully expressed. Two activation modes are described as: distal fraction of the arch from behind the molar tube (not exceeding 1 mm per appointment) or retro-ligature activation using a ligature wire tied between the molar tube hook and the distal DKL loop. Its primary advantage is the integration of retraction into a fullarch continuous wire that simultaneously expresses bracket-prescribed torque and angulation. [20]

PG Retraction Spring (Figure 10)

Introduced by Poul jessing of Denmark in 1985, the PG retraction spring is fabricated from 0.016 × 0.022-inch stainless steel wire. Its predominant active element is an ovoid doublehelix loop extending 10 mm apically with two closely spaced helical coils forming an ovoid configuration with a smaller occlusally positioned helix. Activation of 140-160 grams is obtained by separating the two helix sections by 1 mm distally, repeated every 4 weeks.Buccal segment leveling must be finished before insertion because the spring is especially made to withstand rotational and tipping tendencies during retraction but not to correct preexistingrotations or excessive canine inclinations. At 3 mm activation, the anterior M/F ratio is 7 mm; at 1 mm activation, it is 10.5 mm. A self-correcting sequence, biomechanically comparable to the self-correction of the T-loop, from controlled tipping at heavy activation toward near translation as the dog moves and the spring deactivates. After retraction, lingual elastics are used to treat minor residual canine rotations. [21]

K-SIR Arch

Developed by ,The K-SIR (Kalra Simultaneous Intrusion and Retraction) arch developed byDr. Varun Kalra and published in 1998, addresses anterior deep-bite correction and retraction simultaneously within a single continuous archwire. Closed U-loops measuring 7 mm in height and 2 mm in width are integrated at extraction sites using three distinct bend configurations: a 90° centered V-bend at each U-loop that generates equal retraction and intrusion moments; an off-centered 60° V-bend with the shorter arm near the molar tube that increases clockwise moment on the first molar for posterior anchorage augmentation; and a 20° anti-rotation bend that counteracts mesiolingual rotation of the buccal segments. Prior to insertion, trial activation stabilizes the intensity of the V-bend and lessens

stress accumulation. It is most beneficially applied in Group A extraction cases with deep overbite where sequential bite-opening prior to retraction would otherwise extend treatment duration. [22]

Snail Loop (Figure 11)

Introduced by Dr. Pavankumar Vibhute in 2004, the snail loop is fashioned from 0.017 x0.025-inch stainless steel wire by bending a simple omega loop into a progressively tightening spiral. The resulting nested configuration consists of an outer loop of 8 mm height and 6 mm width and an inner loop of 6 mm height and 3 mm width. The spiral geometry maximizes total wire length within the available vestibular space to a degree unmatched by any other commonly used loop design. Finite element analysis by Rao et al. (2013) confirmed that the snail loop achieves the lowest LDR of any tested design - lower than both the Opus loop and the tear-drop loop - conferring the most constant force delivery and widest activation range before reactivation. Vibhute et al. (2008) reported twice the activation potential of a stainless steel omega loop before permanent deformation. This also minimizes soft tissue irritation. The main drawback is the difficulty of manufacturing; chairside manufacture is technically challenging because to the spiral geometry, which necessitates exact sequential bending with the right pliers. [23]

Rectangular Loop (R-Loop)

The rectangular loop, described by Drs. Vittorio Cassiafesta and Birte Melsen, is a versatile design fabricated primarily in TMA wire whose weldability permits joining segments of different cross-sections - typically 0.018-inch or 0.017 × 0.025-inch, providing a large working range. Being inserted and held at both ends, it constitutes a statically indeterminate force system. It is the most versatile design for correcting single-tooth discrepancies in all three planes of space that is first, second, and third order corrections, while transferring undesirable reciprocal forces to the anchorage unit. In the context of segmented arch mechanics, Marcotte described the R-loop specifically for intrusion, extrusion, and rotation correction of individual canines and premolars, which can simultaneously superimpose a rotational couple on a translatory force. [24]

Cherry Loop

Described by PerettaRedento in 2002, the cherry loop is constructed from 0.017 x 0.025-inch stainless steel wire. A largediameter round loop of 8 mm width is bent using a Rouland plier to a height of 8-9 mm, opening 3-4 mm at the occlusal end to prevent stress concentration and deformation. It is specifically designed for molar protraction and is placed at one-half distances within the extraction space when moving molars mesially. Its rounded largediameter apical configuration distributes bending stress and reduces fracture tendency, while the wide occlusal opening provides a comfortable activation range for the relatively heavy forces required to protract molars. [25]

Bulbous Helical Loop (Figure 12)

A variant within the helical loop category, the bulbous helical loop is fabricated at the terminal end of a 0.020 × 0.025-inch archwire to a height of 7.5 mm, positioned flush against the second-order bends with the helix wound toward the lingual surface during fabrication.Before insertion, it is activated by opening approximately 1 mm, generating a distalizing force on the posterior teeth. It is employed during mandibular anchorage preparationcounteracting the mesializing tendency of the posterior anchorage unit during anterior retractionand also serves for molar uprighting. Its helical element provides the biomechanically gentle, continuous light forces characteristic of all helical designs.

Ricketts Canine Retraction Spring

Described by Robert Ricketts in 1976, the Ricketts canine retraction spring is a double vertical helical T-closing loop with extended crossed arms, fabricated in the maxillary arch from 0.016 x 0.022-inch stainless steel wire of 70 mm length. It generates a canine retraction force of approximately 50 g for 1 mm of activation, with 3-4 mm of activation required for individual canine retraction. The mandibular version is more compact, fabricated from 0.016 × 0.016-inch blue Elgiloy, generating 75 g per millimeter of activation with 2-3 mm of activation needed. The double helical configuration provides a combination of spring gentleness and torque resistance that makes it suited to sequential two-step retraction protocols within bioprogressive therapy.

Ballista Spring

Introduced by Harry Jacoby in 1979, the ballista spring is a purpose-designed appliance for managing palatally impacted maxillary canines. It consists of two parts: a horizontal arm inserted into both the headgear and edgewise molar tubes and ligated to the first premolar bracket as a hinge axis, which stores torsional energy when deflected; and a vertical arm bent at 90° terminating in a small loop for ligature or elastic attachment. The spring delivers 60-100 g (0.016-inch wire) or 120-150 g (0.018-inch wire) of controlled vertical and palatal force to the impacted tooth. Its key advantage is adjustability: inclining, lengthening, or shortening the vertical arm modifies the direction of traction that is anteroposterior, toward the midline, or toward the arch ,allowing precise navigation of the canine away from adjacent root apices before eruption. [26]

Multiloop Edgewise Archwire (MEAW)

Introduced by Dr. Young H. Kim in 1967, the MEAW consists of L-shaped horizontal loops at each interproximal contact from distal of the lateral incisors to the mesial of the second molars — five loops per side. Wire specifications are 0.016 × 0.022-inch SS for a 0.018-inch slot and 0.018 x 0.022-inch SS for a 0.022-inch slot. The MEAW is 2.5-3 times longer than a standard archwire, reducing forces to approximately one-fifth of a standard wire and delivering consistent low-level continuous forces. Each loop has four components: a horizontal loop (reducing vertical force and enabling vertical tooth control); a vertical leg/breaker (ensuring individual tooth independence); a loop base (where tip-back and torque activations are incorporated); and a horizontal archwire portion (inserted into the bracket slot, kept straight). Progressive tip-back bends of 3-5° at each loop base from first premolars to second molars with a total of 15-20° to upright the posterior teeth, reconstruct the occlusal plane, and create conditions for anterior extrusion. Vertical elastics drive anterior teeth into the open bite space. [27,28]

Mollenhauer Aligning Auxiliary

The Mollenhauer aligning auxiliary is an adjunct spring typically 0.016-inch round stainless steel or TMA which is applied to a single tooth requiring individual correction during the aligning and leveling phase, without disturbing the continuous main archwire. While the main archwire continues to level the remaining dentition, it is engaged in or tied over the bracket of the misaligned teeth. With the primary archwire acting as the anchorage reference, this segmented technique reduces reciprocal effects on neighbouring teeth while applying a precisely specified correction force to a single severely rotated, pointed, or lingually displaced tooth. Palatally misplaced lateral incisors, severely rotated premolars, and pointed canines that would require excessively high archwire forces if treated with a continuous wire alone are the most prevalent conditions for which it is employed.

Begg's Torquing Auxiliary (Torquing Loop)

After the crown-tipping retraction of Stages 1 and 2, Begg's torquing auxiliary, a compressed vertical loop, is utilized in Stage 3 of the Begg light-wire differential force procedure to provide lingual root torque to the anterior teeth. It is made of 0.014-inch or 0.016-inch stainless steel wire and is shaped to press against the incisor crown's gingival surface. This creates a lingual force at the archwire and a labial force at the bracket, creating a couple that pushes root apices lingually to achieve the proper axial inclination. An M/F ratio of>12:1 is required for pure root movement. In the Begg framework, the torquing auxiliary completes the sequential movement to correct final incisor inclination without requiring bracket archwire torque expression by compensating for the torque that is accrued during the initial uncontrolled tipping retraction phases.[29]

Complications and Risk Management in Loop Mechanics

Inadequate loop design, activation, or clinical monitoring can lead to a number of issues despite the biomechanical benefits of frictionless loop mechanics.

- The most frequent negative effect of loop mechanics is anchorage loss. Unintentional molar mesialization can be caused by inadequate posterior consolidation, incorrect loop orientation, or excessive activation. Transpalatal arches, Nance holding appliances, or temporary anchorage devices (TADs) in conjunction with suitable differential M/F ratios at the beta bracket end to increase posterior resistance are necessary for prevention.

- When the M/F ratio supplied at the bracket is inadequate for the intended tooth movement, **uncontrolled tipping** and torque loss occur. Anterior flaring, bite deepening, and loss of incisor torque can result from improper loop height, insufficient preactivation bends, or over-activation beyond the elastic limit.
- Prolonged treatment duration, jiggling movements from recurrent over-activation, and high activation pressures all worsen **root resorption**. The biological optimum of 35–60 g for tipping and 70–120 g for body movement must be maintained, and loop activation shouldn't go over 1 mm every session.
- When stainless steel loops are repeatedly activated and deactivated, there is a risk of **wire fatigue and loop distortion**. TMA is the material of choice for advanced retraction springs since it resists fatigue far better than stainless steel. Regular monitoring at intervals of four to six weeks is necessary to quickly identify patient distortion of loops between sessions.
- **Soft Tissu e**near bulky or tall loops that press against the buccal mucosa or alveolar gingiva cause irritation.The Opus loop, snail loop, and mushroom loop are simple designs that reduce vestibular projection and improve patient comfort, especially for those with shallow vestibules.
- The box loop and other complicated loop designs are known to be hampered by **plaqueaccumulation**. Before and during loop therapy, patients need to be reminded to practice good dental hygiene in order to avoid iatrogenic periodontal problems. [30]
- Unlike sliding mechanics, **fabrication errors** offer a special risk in loop mechanics. Large-scale, irreversible faults in tooth movement can result from even small flaws in loop geometry, gable bend angulation, or loop centricity.

Friction Versus Frictionless Mechanics

The management of orthodontic extraction space is broadly classified in two mechanical philosophies: frictional (sliding) mechanics and frictionless (loop) mechanics, each carrying distinct biomechanical characteristics, clinical advantages, and inherent limitations. In sliding mechanics, the bracket moves along a continuous, to move the teeth. Despite being commonly used in pre adjusted edgewise systems, it is operationally simple. Resistance to sliding, a multi factorial phenomenon of friction, binding, and notching at the bracket archwire contact reported by Kusy and Whitley, counteracts its simplicity. Resistance increases dramatically after the contact angle beyond a critical threshold, resulting in unpredictable force delivery, anchoring loss, uncontrollable anterior tipping, and overbite deepening. Elastomeric chains, which are frequently utilized as the activating component, require periodic reactivation and compromise force consistency because they lose 50–70% of their initial force within the first day of application due to water and saliva absorption. [31]

The bracket-wire sliding contact is completely eliminated in frictionless mechanics loop springs in place of the continuous archwire as the force-generating component. The spring produces more consistent, predictable, and controllable tooth movement by independently delivering the necessary moment-to-force ratio in three dimensions. Through differential M/F ratios, independent control over anterior and posterior tooth segments, and the capacity to achieve complex movements like translation, root torque, simultaneous intrusion, and retraction—all of which sliding mechanics cannot consistently duplicate the clinician is able to precisely regulate anchorage. Tipping, translation, and root movement are the three closure that both systems go through. On the other hand, a well-designed loop appliance consistently maintains a larger activation range, a more steady force delivery, and a more constant center of rotation. [32] Neither strategy is always better. Anchorage requirements, necessary tooth movements, clinical knowledge, and the particular biomechanical goals of each patient continue to decide the best option.

CONCLUSION

Loop mechanics is used for initial alignment or later space closure, it is essential for regulated orthodontic tooth movement. No single loop design is universally better, as several assessments confirm; instead, the right choice relies on the particular biomechanical demand, anchorage needs, and clinical situation. Since even small design flaws can result in unpredictable tooth movement, effective loop therapy depends on a solid understanding of wire

characteristics, activation range, and moment-to-force ratios. While more recent configurations continue to enhance anchorage conservation and patient comfort, historical contributions by Strang, Stoner, Burstone, and other innovators have gradually improved loop shape to balance flexibility with sufficient force delivery. Orthodontic space closure should ultimately be customized, guided by careful diagnostic and treatment planning as opposed to a set technique. Neither friction nor frictionless mechanics is universally superior; the optimal strategy remains individually determined by the diagnosis, anchorage demands, required tooth movements, and clinical expertise of the treating orthodontist.

ABSTRACT

Gout was first described by Hippocratus. The term 'gout' is derived from Latin word 'gutta' and French word gote, both meaning a drop of liquid. A long time ago, people believed that gout was caused by drops of thick body fluids flowing from the blood into the joints. Gout is a type of joint disease that causes inflammation. It happens when there is too much uric acid in the blood. Uric acid forms sharp crystals called monosodium urate, which build up in the joints and cause swelling and pain. In the last twenty years, the number of people with gout has doubled, mostly because of changes in what people eat.

Keywords: Gout, Homoeopathy, Hyperuricemia, Purine-rich diet, Serum uric acid**.**

INTRODUCTION

Gout is a type of inflammatory arthritis caused by high levels of urate in the blood, which stays elevated for a long time. This leads to too much urate in the body, making crystals of monosodium urate form and build up in the joints. Gout is a metabolic illness that mainly affects women who have gone through menopause and middle-aged to

elderly males. Gout affects 1-4% of the general population, but in people over 80, that number can jump to 10% in males and 6% in women. Men experience the condition two to four times more frequently than women do worldwide. The biomarker for gout is hyperuricemia.

MATERIALS AND METHODS

A single arm, retrospective, non-randomised observational study which was conducted on 30 patients with the diagnosis of gout at the outpatient department of White Memorial Homoeo Medical college and Hospital, Attoor over a duration of six months. Each patient was provided with a patient information sheet in local vernacular Tamil language detailing the objectives, methods, risks and benefits of participating and confidentiality issues. Before enrolment, written informed consent was taken from the patients.

- **Outcome assessment:** Outcome measurements of this study were done based on laboratory investigations of serum uric acid level in gout patients.
- **Intervention and Follow - Up:** All patients received suitable homeopathic medicines that were tailored to their individual needs according to homeopathic guidelines. They were also given advice on improving their lifestyle by making changes to their diet and daily routine. If needed, their cases were carefully reviewed and organized using the repertory method. The treatment was repeated as necessary based on each patient's specific needs. Each patient was treated for six months, and follow-up visits were scheduled at least once a month or more frequently if needed by the patient.
- **Statistical analysis;** Before and after treatment assessment were done and hypothesis was analyzed by paired 't' test.

RESULT

From this study it was found that men (53%) are more commonly affected than females (47%), the affected age group between 36-40 years were commonly affected (60%),the most commonly affected site is right side (68%) . Patients coming from high socioeconomic status (46.7%) were likely to develop the disease. The Group of people who consumes non-vegetarian foods (83.4%) were commonly affected, the affected group is people who had addictions to alcohol and smoking (23%). The medicine Lycopodium Clavatum were prescribed for (26.7%) cases, potency selected for majority of cases were 200 (90%) and 27 cases (90%) were prescribed with 200th potency, with an average reduction of 1.22mg/dl was noted and 3 cases (10%)were prescribed with 30th potency, , with an average reduction of 1.03mg/dl in the levels of serum uric acid. 83% of cases had marked improvement in the reduction of serum uric acid level after the homoeopathic treatment. The mean uric acid level before the treatment was 7.28mg/dl, and after the treatment, it decreased to 6.07 mg/dl. The standard deviations were .331 before the treatment and .622 after the treatment, show that uric acid levels were more variable after the treatment. The standard error means were .060 before the treatment and .114 after the treatment indicate the precision of the sample means. The mean difference between the two time points is 1.210 mg/dl, with a t-value of 11.171 and a p-value of .000, indicating this difference is highly statistically significant. The 95% confidence interval (0.988 to 1.432) suggests we are 95% confident that the true mean decrease lies within this range. In simple terms, the intervention significantly reduced uric acid levels in the subjects. Since p value < 0.05, null hypothesis is rejected. The t-test value is 11.171, which is greater than table value, the null hypothesis is rejected. We can conclude that the Homoeopathic medicines are effective in reducing hyperuricemia in gout patients.

DISCUSSION

Early onset gout, majority affected between 36-40 years of age suggesting lifestyle and dietary influences. There is higher prevalence in males which is consistent with known epidemiology of gout. Right side involvement is the most common which is due to gout presentation in the first MTP joint. High socioeconomic group is mostly affected due to more exposure to purine rich foods, sedentary lifestyle and alcohol consumption. Non vegetarians are commonly affected, reinforcing the role of purine rich food in increasing serum uric acid levels. Addictions such as alcohol consumption and smoking are associated with increase in the levels of serum uric acid. Lycopodium clavatum is the most used medicine. The observations were analyzed using paired "t" test. It showed that there is significant change in before and after values of serum uric levels after treatment.

ABSTRACT

Chronic Obstructive Pulmonary Disease is a progressive pulmonary condition that reduces functional capacity and significantly affects the quality of life. Patients frequently limit their physical activity when the condition becomes severe, resulting in negative impacts on their ability to perform physical activity and causing severe dyspnea. However, physical activity and exercise are essential for managing COPD, as they can improve exercise capacity, endurance, and overall well-being. There is a low-impact cardiovascular exercise known as Nordic walking, which is performed with two specially designed poles, and has shown promise for the management of COPD. This exercise helps to enhance maximum oxygen consumption (VO2max), endurance, and functional capacity by engaging both upper and lower limbs. To evaluate the effectiveness of Nordic walking on pulmonary function, functional capacity, and quality of life among individuals with COPD. This study will be conducted as a single-center pilot randomized clinical trial with 18 participants diagnosed with COPD. Participants will be randomly allocated into intervention and control groups by using lottery method. The intervention will be conducted for 6 weeks with three sessions per week. Outcome measures will include pulmonary function assessed by spirometry, functional capacity using the 6MWT, and quality of life assessed using the COPD Assessment

Test (CAT). Data will be analyzed using Statistical Package for the social sciences. If the data will normally distributed, a parametric test will be used. For within-group analysis, a paired t-test will be used; for between-group analysis, an independent t-test will be used, If the data will not normally distributed, then non-parametric tests, i.e., Wilcoxon Signed-Rank test will be used for within-group analysis, and the Mann-Whitney U test will be used for between-group analysis.

Keywords: Quality of life, Nordic walking, Exercise tolerance, Pulmonary disease

INTRODUCTION

Chronic Obstructive Pulmonary Disorder is a heterogeneous lung condition characterized by chronic respiratory symptoms (dyspnea, cough, sputum production and / or exacerbation) due to abnormalities of the airway (bronchitis, bronchiolitis) and / or alveoli (emphysema) that cause persistent, often progressive, airflow obstruction.[1] According to the Global Initiative for Chronic Obstructive Lung Disease case definition, COPD affected nearly 391 million people worldwide in 2019 and remains one of the leading causes of morbidity and mortality, particularly among older adults and smokers. In 2019, approximately 212.3 million cases and 3.3 million deaths were reported globally, making COPD the third leading cause of death worldwide. Its prevalence continues to rise with age, and projections suggest that by 2060, COPD may account for more than 4 million deaths annually. Individuals with COPD are also at increased risk of falls, particularly during acute exacerbations, further increasing disability and healthcare burden. [2] COPD pathogenesis involves oxidative stress, chronic inflammation, and imbalance between antiprotease and protease because of long-term exposure to pollutants and smoking. Enzymes and cytokines secreted by the inflammatory cells such as neutrophils, macrophages which can damage lung tissue [3-4] Additionally, there is destruction of the alveolar wall due to inactivation of protective enzymes. Dysregulation of the immune system and recurrent bacterial infections lead to disease progression. [5-6]

These pathophysiological changes lead to significant reductions in functional capacity, with patients commonly experiencing exertional dyspnea, early fatigue, and diminished exercise tolerance. Consequently, quality of life declines as limitations in physical activity, social participation, and emotional well-being intensify. [7] Clinically, COPD presents with shortness of breath (dyspnea), production of sputum and chronic cough. [8] The cough is mainly and notably productive in the morning and obstructs airflow over time. Tightness in chest and wheezing can be the result of obstruction in bronchi and mucus hypersecretion.[9] As chronic obstructive pulmonary disorder progresses, there is often weight loss, exertional dyspnea, and a decrease in physical activity. [10] In advanced conditions, individuals may present with peripheral oedema, cyanosis, and cor pulmonale (a sign of right heart failure) may appear due to pulmonary hypertension and chronic hypoxemia. Apart from pulmonary clinical manifestations, COPD also has systemic consequences like cardiovascular complications, osteoporosis and skeletal muscle wasting. These signs contribute to increased mortality and reduce quality of life. [11] Pulmonary rehabilitation plays a central role in mitigating these deficits through individualized exercise training, breathing retraining, airway clearance techniques, education, and behavioral modification strategies, collectively aimed at improving symptoms, enhancing functional status, and restoring overall quality of life in individuals with COPD.[12] Investigations from 2022-2025 continue to focus on the integrated benefits for managing chronic obstructive pulmonary disease with pharmacotherapy, pulmonary rehabilitation (PR), and exercises. PR programs that are based on exercise remain central to enhance quality of life, exercise tolerance and muscle strength. In 2023, JAMA review on PR emphasizes gradual progression in duration and intensity of exercise from maximal benefit. [13]

A full-body aerobic exercise Nordic walking (NW) or Pole Walking which originated in Finland in 1930. At the beginning it was designed as off-season training for cross-country skiers. There is a specially designed pole for walking which engages both upper and lower body. Over time, this has become a recognized rehabilitative exercise

program for respiratory illnesses. [14] There are recent literature states Nordic walking offers a low-impact cardiovascular exercise, enhances oxygen uptake, improves quality of life, increase muscular strength, decrease dyspnea and improve exercise tolerance. [15]

REVIEW OF LITERATURE

Randomized controlled trial conducted involving 60 patients with the aim to determine the short- and long-term effects of Nordic walking on COPD patients daily physical activity and exercise capacity. Participants were randomly assigned into two groups: a Nordic walking group and a control group. The intervention group carried out under the supervision 4 times per week for 3 months at moderate intensity (75%), whereas control group underwent no structured exercise. Evaluations were conducted at baseline, three, six and nine months. The study demonstrated that Nordic walking resulted in significant improvement in functional capacity and daily physical activity. [16] An experimental study was conducted on 15 COPD patients to investigate physiological adaptation to Nordic walking. The participants were administered under multiple exercise protocols, including 6-minute Nordic walk, incremental shuttle walk test and 6-minute walk test on sand and solid ground. The clinical outcomes included heart rate, minute ventilation, oxygen uptake and perceived exertion using modified Borg Scale. The findings established that Nordic Walking showed a notably higher VO2 level as compared to standard walking test. The outcomes provided evidence that Nordic walking induces higher physiological response without exacerbation of dyspnea, emphasizing its implications for clinical practice as an effective training intervention in COPD rehabilitation. [17] Nordic Walking has demonstrated benefits in pulmonary rehabilitation, yet limited evidence exists regarding its effectiveness in improving pulmonary function, functional capacity, and quality of life among individuals with COPD. Therefore, this study aims to investigate the effectiveness of Nordic Walking as a component of pulmonary rehabilitation.

Study Objectives

- To evaluate the effectiveness of Nordic walking on pulmonary function.
- To evaluate the impact of Nordic walking on functional capacity.
- To evaluate the impact of Nordic Walking on quality of life.

Research Hypothesis Null Hypothesis:
Nordic walking will have no significant impact on pulmonary function, functional capacity and quality of life in individuals with COPD.

Alternate Hypothesis
Nordic walking will have a significant impact on pulmonary function, functional capacity and quality of life in individuals with COPD.

MATERIAL AND METHODS

This is a single center, parallel, pilot study. Participants in this study will be recruited via criterion-based purposive sampling from OPD of Respiratory Medicine at MMIMSR, Mullana-Ambala, Haryana, from November 2025 to April 2026.

Eligibility criteria
Participants will be included if they are clinically diagnosed with COPD with Grade II to IV, have at least 18 years of age, willing to participate, and have the ability to walk. [18] Participants with any musculoskeletal disorder, diagnosed with any other respiratory condition, cardiac arrhythmia, diseases that decrease exercise capacity (Anemia, electrolyte imbalance), acute myocardial infarction (MI) in the last 6 months, resting heart rate more than 120 will be excluded. [19]

Sample Size

The participants for the study will be recruited using purposive sampling. To determine the recruited sample size G* Power software 3.1.9.7 used drawing on the effect size (Cohen's d) derived from the result of pilot study.

To calculate the effect size, the mean difference with in the group was taken into consideration alongside the pooled standard deviation, on the basis of given formula:

$d = \frac{M1-M2}{SD\ pooled}$

d = Cohen's d

M1 = Mean of Group 1

M2 = Mean of Group 2

SD = Standard Deviation

Pulmonary function mean change scores of FEV1 pre- intervention 1.25 ± 0.60 and post-intervention 1.53 ± 0.74 with an effect size of 0.41, indicate that moderate treatment effect. Based on effect size 94 samples required. FVC showed mean value pre and post intervention 2.23 ± 1.02 and 2.34 ± 1.05 respectively with 0.10 effect size, indicating very small effect and required 3140 sample. Mean values of FEV1/FVC 56.15 ± 15.33 pre-intervention and 63.92 ± 15.01 post-intervention with an effect size of 0.51 representing moderate effect size and 62 sample size required. Functional capacity measured by 6MWT with mean values 338.33 ± 28.74 and 365.00 ± 39.29, with effect size of 0.77 which demonstrate large effect size and required 28 samples. Mean values of CAT in 26.22 ± 6.05 pre-intervention and 21.39 ± 7.03, with effect size of 0.74 and estimated sample size 30. The estimated sample size requirement for most variables was comparatively large because of modest effect sizes. The study intends to enroll 36 participants to support feasibility and met methodological rigor. Individuals involved in the pilot study will not include in the main trial.

Study Procedure

Ethical clearance for the study was granted by the Institutional Research Ethics Committee (IEC-3477), and the trial was formally registered in the prospective registry under the reference number CTRI/2025/09/095386. The study will be conducted in accordance with the revised Declaration of Helsinki, 2013. Documented informed consent will be collected from the subjects before their participation, and participants will receive comprehensive study information. After participants enrolment, demographic details, including weight, height, and BMI, will be recorded. Every participant will continue to their prescribed medical treatment regimen throughout the treatment period. The participants will then be allocated into two groups: an intervention group and a control group. The allocation will be based on an allocation identification (ID) number that will later be linked to the names of the individuals on the list. Once assigned, the order cannot be changed. Patients will be allocated to groups through a lottery- based randomization.

Outcome Measures Pulmonary Function Test

The pulmonary function test FVC, FEV1, and FVC/FEV1 will be evaluated by using a spirometer (RMS Helios 401) in a seated position. Three acceptable maneuvres will be documented and the best graph will be used for analysis. [20]

6 Minute Walk Test

Functional capacity will be assessed using the 6MWT in accordance with the ATS guidelines. The test will be performed along a straight track of 30 meters on which participants will walk as far as possible for 6 minutes at their own normal pace. Overall distance ambulated in 6 minutes will be recorded as an outcome measure. The assessment will be terminated if the participants experience dyspnea, chest pain, or dizziness. [21]

COPD Assessment Test (CAT)

This assessment test will be administered to determine disease – related to assess quality of life, which is a clinically validated evaluation tool consisting of 8 items evaluating the symptoms such as activity limitation, cough, breathlessness, and sputum. Each item is scored from 0-5, with total score 0-40, accordingly to higher score

recommend poor health condition. This questionnaire has shown good reliability and validity in patients with COPD and frequently applied across clinical and research environments. [22]

Intervention

Training session divided into Three Stages: Warm-up, treatment intervention and cool-down, implemented 3 sessions a week for 6 consecutive weeks.

Warm-up phase: The 6 exercise will be carried out for 10 minutes each, performing in one set of repetitions for each exercise. Example of warm-up exercise include neck tilt, neck rotation, trunk rotation, hip rotation, static march and thoracic expansion.

Experimental Group (Nordic walking): Participants in Nordic Walking group will train on a 60 meter walkway using walking poles for 20 minute session while exercise intensity will be maintained between 60%-80% of maximum heart rate and modified borg scale rated at dyspnea or fatigue 4-6. [18]

ABSTRACT

Network intrusion detection has become increasingly challenging due to the rapid evolution of cyber attacks, severe class imbalance, high-dimensional traffic features, and concept drift in dynamic network environments. Traditional machine learning and deep learning-based intrusion detection systems often suffer from poor minority attack detection, over fitting, and reduced adaptability when exposed to continuously evolving traffic patterns. To address these limitations, this study proposes an Adaptive Quasi-Recurrent Stacked Auto encoder (A-QRSAE) framework integrated with temporal pooling, GAN-augmented minority attack generation, Boruta-based feature optimization, and drift-aware incremental learning for intelligent network intrusion detection. The proposed model employs Boruta feature selection to identify the most relevant network traffic attributes while reducing dimensional redundancy. A Quasi-Recurrent Neural Network (QRNN)-based stacked auto encoder is introduced to efficiently capture temporal dependencies and sequential attack behaviors with lower computational complexity than conventional recurrent architectures. To mitigate class imbalance, a Wasserstein Generative Adversarial Network (WGAN) mechanism is incorporated for synthetic minority attack generation, thereby improving rare attack classification performance. Furthermore, a concept drift-aware adaptive learning module is integrated to continuously update the detection model under evolving network conditions. Bayesian hyper parameter optimization is additionally utilized to enhance model generalization and detection efficiency. The study contributes a scalable, adaptive, and computationally efficient intrusion detection framework suitable for modern IoT, IIoT, cloud, and enterprise cybersecurity infrastructures.

Keywords: Intrusion Detection System, Quasi-Recurrent Neural Network, Autoencoder, GAN, Concept Drift, Boruta Feature Selection, Cybersecurity, Deep Learning, IoT Security, Network Anomaly Detection.

INTRODUCTION

The rapid expansion of digital communication technologies, cloud computing infrastructures, Industrial Internet of Things (IIoT), and smart interconnected systems has significantly increased the complexity of modern cybersecurity environments. With the growing dependence on network-based services, cyberattacks such as Distributed Denial of Service (DDoS), ransomware, botnet infiltration, phishing, privilege escalation, and data exfiltration have become increasingly sophisticated and difficult to detect using traditional security mechanisms. Intrusion Detection Systems (IDS) therefore play a critical role in identifying malicious activities and protecting network infrastructures against evolving cyber threats.

MATERIALS AND METHODS

Dataset Collection and Experimental Environment

The proposed Adaptive Quasi-Recurrent Stacked Autoencoder (A-QRSAE) framework was evaluated using multiple benchmark intrusion detection datasets to ensure robustness, scalability, and generalization across heterogeneous network environments. The datasets selected for this study include NSL-KDD, UNSW-NB15, CICIDS2017, Edge-IIoTset, and CICIoT2023 datasets. These datasets contain both normal and malicious traffic records representing diverse attack categories such as denial-of-service attacks, probing attacks, privilege escalation, botnet activities, brute-force intrusions, web attacks, infiltration, and IoT-based malicious activities. [4], [5], [6], [7], [8] The NSL-KDD dataset was selected because it eliminates redundancy issues present in the original KDD Cup 99 dataset while maintaining benchmark significance in intrusion detection research. [4] UNSW-NB15 provides realistic modern network traffic generated using contemporary attack scenarios and normal user behaviors. [5] CICIDS2017 contains up-to-date attack traffic and realistic benign network communication patterns suitable for evaluating deep learning-based IDS models. [6] Edge-IIoTset and CICIoT2023 datasets were incorporated to evaluate intrusion detection capability within Internet of Things (IoT) and Industrial Internet of Things (IIoT) environments characterized by highly dynamic and heterogeneous traffic behaviors. [7], [8] The experimental simulations and model training procedures were conducted using Python-based machine learning libraries including Tensor Flow, Keras, Scikit-learn, NumPy, and Pandas within a GPU-enabled computational environment. Bayesian hyper parameter optimization was implemented to improve model convergence and detection performance. [11]

Data Preprocessing

Data preprocessing was performed to improve data quality, remove inconsistencies, and prepare the datasets for deep learning analysis. Initially, duplicate and corrupted records were removed from the datasets to avoid biased learning behavior. Missing values were handled using mean-based imputation and normalization techniques depending on the data distribution characteristics. Categorical traffic attributes including protocol types, services, and connection states were transformed into numerical representations using label encoding and one-hot encoding methods. Feature normalization was performed using Min-Max scaling to transform all numerical attributes into a uniform range between 0 and 1. The normalization process reduces feature dominance and improves neural network convergence during training. Since intrusion datasets often contain highly imbalanced attack distributions, minority attack samples were identified and isolated for synthetic augmentation using GAN-based learning mechanisms. The datasets were further divided into training, validation, and testing subsets using stratified sampling to preserve attack class distributions across all subsets. Temporal ordering was also maintained during sequential data processing to preserve network traffic dependencies for QRNN-based learning.

Boruta-Based Feature Selection

High-dimensional intrusion datasets frequently contain redundant, irrelevant, and noisy traffic attributes that increase computational complexity and reduce model interpretability. To overcome this limitation, the proposed framework employs the Boruta feature selection algorithm to identify the most informative traffic features associated

with intrusion detection. Boruta is a wrapper-based feature optimization method built around the Random Forest classifier and is capable of identifying both strong and weak feature relevance. [12], [13], [14] The Boruta algorithm iteratively compares original traffic attributes with randomized shadow features generated through feature permutation. Features that consistently outperform their shadow counterparts are considered important and retained for model training. The feature selection process reduces dimensional redundancy while improving classification efficiency and model generalization. The selected optimal feature subset was then forwarded to the QRNN-based stacked auto encoder for temporal representation learning and anomaly reconstruction.

Quasi-Recurrent Stacked Autoencoder Architecture

The proposed A-QRSAE model integrates Quasi-Recurrent Neural Networks (QRNNs) within a stacked autoencoder framework to efficiently capture temporal intrusion patterns from sequential network traffic data. QRNN architectures combine convolutional operations with recurrent pooling mechanisms to achieve faster sequence learning while maintaining temporal dependency modeling capability. [1] The encoder component compresses high-dimensional traffic features into low-dimensional latent representations capable of preserving critical intrusion characteristics. Temporal pooling layers are incorporated to improve sequential feature extraction and long-range dependency learning across network traffic sequences. The decoder subsequently reconstructs the compressed representations to identify deviations associated with anomalous network activities. Compared with conventional LSTM-based architectures, QRNN-based autoencoders provide reduced computational complexity, faster parallel processing capability, and improved scalability for large-scale intrusion detection environments. [1], [26], [31]

GAN-Based Minority Attack Augmentation

Class imbalance remains a major challenge in intrusion detection because minority attack classes are frequently underrepresented compared with normal traffic records. To address this issue, the proposed framework incorporates a Wasserstein Generative Adversarial Network (WGAN)-based augmentation module to generate realistic synthetic minority attack samples. [2], [9], [10], [22] The GAN architecture consists of two competing neural networks: a generator and a discriminator. The generator learns the probability distribution of minority attack classes and generates synthetic attack samples, while the discriminator attempts to differentiate real attack samples from generated samples. Through adversarial training, the generator gradually produces highly realistic synthetic intrusion patterns that improve classifier learning balance. GAN-assisted augmentation significantly enhances minority class representation and improves detection capability for rare attack categories including user-to-root attacks, remote-to-local intrusions, botnet activities, and zero-day anomalies.

Drift-Aware Incremental Learning

Modern network traffic environments continuously evolve due to changes in user behavior, device communication patterns, and emerging cyberattack strategies. Such dynamic variations result in concept drift where previously learned data distributions become outdated. Static IDS models therefore experience gradual performance degradation over time. [15], [16], [17], [18], [19] To overcome this limitation, the proposed A-QRSAE framework integrates a drift-aware incremental learning mechanism capable of continuously adapting to evolving traffic distributions. Statistical drift monitoring techniques are employed to identify distributional changes in incoming network traffic streams. Upon detecting significant drift, the model incrementally updates its parameters using newly observed traffic patterns without requiring complete retraining from scratch. The adaptive incremental learning strategy improves long-term model stability, reduces catastrophic forgetting, and enhances resilience against evolving attack behaviors in real-world deployment environments.

Bayesian Hyper parameter Optimization

Deep learning model performance is highly dependent on optimal hyper parameter configuration. Manual tuning of hyper parameters is computationally expensive and often produces suboptimal results. Therefore, Bayesian Optimization was employed to automatically identify optimal hyper parameter combinations for the proposed

framework. [11] The optimization process was applied to parameters including learning rate, QRNN hidden units, batch size, dropout ratio, latent feature dimension, GAN training epochs, and reconstruction thresholds. Bayesian optimization iteratively updates probabilistic surrogate models to efficiently explore the hyper parameter search space while minimizing computational overhead. The optimized parameter configuration significantly improved detection accuracy, convergence stability, and generalization performance across all evaluated datasets.

Proposed A-Qrsae Framework

System Architecture Overview

The proposed Adaptive Quasi-Recurrent Stacked Autoencoder (A-QRSAE) framework is designed to provide an intelligent, adaptive, and computationally efficient intrusion detection mechanism capable of handling large-scale heterogeneous network environments. The architecture integrates Boruta-based feature optimization, QRNN-driven temporal representation learning, GAN-assisted minority attack augmentation, Bayesian hyperparameter optimization, and drift-aware incremental learning into a unified cybersecurity framework. The overall workflow of the proposed system consists of six major stages: Network Traffic Acquisition, Data Preprocessing and Normalization, Boruta-Based Feature Selection, QRNN Stacked Autoencoder Learning, GAN-Assisted Minority Attack Augmentation, and Drift-Aware Adaptive Detection and Classification. The architectural pipeline is designed to maximize intrusion detection accuracy while minimizing computational overhead and maintaining adaptability against evolving attack behaviors.

Network Traffic Acquisition

The first stage of the framework involves collecting raw network traffic records from benchmark intrusion datasets including NSL-KDD, UNSW-NB15, CICIDS2017, Edge-IIoTset, and CICIoT2023. [4], [5], [6], [7], [8] These datasets contain diverse normal and malicious traffic instances representing multiple attack categories encountered in real-world cybersecurity environments. The collected network traffic includes flow-based attributes such as packet length, connection duration, protocol type, source bytes, destination bytes, traffic state information, and temporal communication characteristics. These attributes form the primary input to the proposed intrusion detection architecture.

Data Preprocessing and Normalization

Raw network traffic data often contains noisy, duplicated, missing, and inconsistent records that may negatively influence deep learning performance. Therefore, preprocessing operations are applied before feature extraction and model training. Initially, corrupted records and duplicate entries are removed from the datasets to improve data consistency. Missing numerical values are handled using statistical imputation techniques, while categorical attributes are transformed into numerical form using label encoding and one-hot encoding methods. To ensure stable neural network convergence, Min-Max normalization is applied to scale all numerical traffic attributes within the range of 0 to 1 using the following normalization equation:

$$x_{norm} = \frac{x - x_{min}}{x_{max} - x_{min}}$$

The normalization process prevents feature dominance and improves optimization stability during QRNN auto encoder training.

Boruta Feature Optimization

High-dimensional intrusion datasets frequently contain redundant and irrelevant traffic attributes that increase computational complexity and reduce detection efficiency. To address this issue, the Boruta feature selection algorithm is incorporated within the proposed framework. [12], [13], [14]

Boruta operates by generating shadow features through random permutation of original traffic attributes and comparing their importance scores using Random Forest estimators. Features that consistently outperform shadow attributes are retained, while irrelevant features are discarded.

The optimized feature subset significantly reduces dimensional redundancy while preserving critical intrusion-related information required for effective anomaly detection.

QRNN-Based Stacked Autoencoder Learning

The core learning component of the proposed framework is the Quasi-Recurrent Neural Network (QRNN)-based stacked autoencoder. QRNN combines convolutional feature extraction with recurrent temporal pooling operations to efficiently learn sequential dependencies from network traffic streams. [1] Unlike traditional recurrent architectures such as LSTM and GRU, QRNN enables parallelized sequence computation while preserving temporal learning capability, thereby reducing training complexity and improving scalability. The encoder compresses high-dimensional traffic data into compact latent representations capable of preserving hidden intrusion characteristics. Temporal pooling layers are integrated to improve sequential pattern extraction across long network communication sequences.

The latent representation generated by the encoder is expressed as:

$$h_t = f(Wx_t + Uh_{t-1} + b)$$

where:

x_t represents the input traffic vector,

h_t denotes the hidden state representation,

W and U are learnable weight matrices,

b represents the bias parameter,

f denotes the activation function.

The decoder reconstructs the compressed latent features to identify deviations between original and reconstructed traffic patterns. Higher reconstruction errors generally indicate anomalous network behavior.

The reconstruction loss is computed using Mean Squared Error (MSE):

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(x_i - \hat{x}_i)^2$$

where:

x_i denotes the original feature vector,

$\hat{x}_i$ represents the reconstructed output,

n indicates the total number of samples.

Feature Selection Using Boruta

Importance of Feature Selection in Intrusion Detection

Modern intrusion detection datasets contain a large number of network traffic attributes representing flow characteristics, packet statistics, protocol information, temporal communication behaviors, and content-based features. Although high-dimensional traffic information improves descriptive capability, the presence of irrelevant, redundant, and noisy features significantly increases computational complexity and negatively affects deep learning model performance. Feature redundancy may lead to: increased training time, over fitting, reduced model interpretability, degraded detection accuracy, and unstable convergence behavior. Therefore, selecting the most informative traffic attributes is an essential preprocessing step for building efficient and scalable intrusion detection systems. Recent studies have demonstrated that optimized feature selection techniques significantly improve anomaly detection performance and computational efficiency in cybersecurity applications. [12], [13], [14] To address these challenges, the proposed A-QRSAE framework integrates the Boruta feature selection algorithm for identifying highly relevant intrusion-related traffic features before deep representation learning.

Boruta Feature Selection Algorithm

Boruta is a wrapper-based feature optimization algorithm built around the Random Forest classifier. Unlike conventional feature ranking techniques that attempt to identify a minimal feature subset, Boruta aims to determine all relevant features associated with the target classification task. [12] The algorithm operates by comparing the importance of original traffic features with artificially generated randomized shadow features. Shadow features are created by randomly permuting the values of original attributes while preserving dataset dimensionality.

The Boruta algorithm performs the following iterative operations:

- Duplicate original features and create shadow features through random permutation.

- Train a Random Forest classifier using both original and shadow features.
- Compute feature importance scores using Random Forest estimators.
- Compare the importance score of each original feature with the maximum importance of shadow features.
- Mark features as:
  - Important,
  - Tentative,
  - Rejected.

Repeat the process iteratively until feature importance stability is achieved. Features that consistently outperform shadow attributes are retained as relevant features, while features with lower importance than shadow variables are removed.

Mathematical Representation of Feature Importance

The feature importance score generated using Random Forest estimation can be represented as:

$$FI_j = \frac{1}{T}\sum_{t=1}^{T} I_{jt}$$

where:

FI_j denotes the importance score of feature j,

T represents the total number of decision trees,

I_{jt} indicates the importance contribution of feature j in tree t.

Features with importance scores significantly greater than their corresponding shadow features are selected for subsequent model training.

Integration with the A-QRSAE Framework

The optimized feature subset generated through Boruta selection was directly supplied to the QRNN-based stacked autoencoder for temporal representation learning. The integration of feature optimization before deep learning training significantly improved convergence stability, reconstruction learning efficiency, anomaly discrimination capability, and minority attack classification performance. The reduced feature space additionally improved GAN training efficiency during minority attack augmentation.

Comparative Significance of Boruta Selection

Several previous studies have highlighted the effectiveness of Boruta-based feature optimization in cybersecurity and anomaly detection tasks. Lifandali et al. demonstrated that Boruta significantly improves classification performance in intrusion detection systems through robust feature relevance estimation. [12] He et al. further showed that Boruta-based anomaly traffic detection models achieve improved detection accuracy and reduced false alarm rates compared with conventional feature selection approaches. [13] Similarly, Harsapranata and Kusumasari reported that Boruta-assisted intrusion detection frameworks improve multi-dataset anomaly classification performance under heterogeneous network conditions. [14] These findings strongly support the incorporation of Boruta optimization within the proposed A-QRSAE framework.

RESULTS AND DISCUSSION

Experimental Evaluation Overview

The proposed Adaptive Quasi-Recurrent Stacked Auto encoder (A-QRSAE) framework was experimentally evaluated using benchmark intrusion detection datasets including NSL-KDD, UNSW-NB15, CICIDS2017, Edge-IIoTset, and CICIoT2023 datasets. The experimental evaluation aimed to analyze the capability of the proposed framework in detecting malicious network traffic under heterogeneous and evolving cybersecurity environments. The proposed framework was compared with several conventional machine learning and deep learning-based

intrusion detection approaches including Support Vector Machine (SVM), Random Forest, CNN-based IDS, LSTM Autoencoder, and Transformer-based IDS architectures.

Performance Evaluation Metrics

The performance of the proposed framework was evaluated using standard intrusion detection evaluation metrics.

Accuracy

Accuracy measures the proportion of correctly classified network traffic instances.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

Precision

Precision measures the proportion of correctly identified malicious traffic among predicted attack instances.

$$Precision = \frac{TP}{TP + FP}$$

Recall

Recall evaluates the capability of the framework to correctly detect actual malicious traffic records.

$$Recall = \frac{TP}{TP + FN}$$

F1-Score

F1-score represents the harmonic mean of precision and recall.

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall}$$

Area Under Curve (AUC)

AUC evaluates the discrimination capability of the intrusion detection framework across different classification thresholds. These evaluation metrics collectively provide comprehensive analysis of anomaly detection capability under balanced and imbalanced intrusion conditions.

Comparative Performance Analysis

The proposed A-QRSAE system demonstrated superior intrusion detection capability compared with conventional machine learning and deep learning-based IDS approaches. The integration of QRNN temporal learning, GAN-assisted augmentation, Boruta feature selection, Bayesian hyper parameter tuning, and drift-aware learning collectively yielded strong and consistent improvements across all benchmark datasets, with the proposed framework demonstrating robust performance under both stable and dynamically evolving network conditions. zation, and drift-aware adaptive learning substantially improved anomaly detection capability across all evaluated datasets. The results presented in Table 1 clearly demonstrate that the proposed A-QRSAE framework achieved the highest overall intrusion detection performance among all evaluated models. The framework achieved an accuracy of 99.12%, precision of 98.87%, recall of 98.65%, and F1-score of 98.76%. The QRNN architecture efficiently captured sequential intrusion behaviors and long-range temporal dependencies while maintaining lower computational complexity compared with conventional recurrent neural networks. GAN-assisted minority attack generation substantially improved the detection capability for rare intrusion categories including user-to-root attacks, remote-to-local intrusions, and IoT malware traffic. The generated synthetic samples improved dataset balance and reduced classifier bias toward majority traffic classes. The Boruta optimization stage reduced dimensional redundancy and eliminated irrelevant traffic features, thereby improving convergence stability and reconstruction learning efficiency within the QRNN auto encoder architecture.

Dataset-Wise Performance Evaluation

The proposed framework was further evaluated individually across all benchmark datasets to analyze generalization capability under heterogeneous cybersecurity environments. The dataset-wise evaluation results presented in Table 2 indicate that the proposed framework maintained consistently high intrusion detection performance across both traditional enterprise network datasets and modern IoT cybersecurity environments. The highest detection accuracy was observed for the CICIDS2017 dataset because of the presence of rich flow-based traffic characteristics and well-

defined intrusion patterns. The framework additionally demonstrated strong robustness within IoT and IIoT environments represented by Edge-IIoTset and CICIoT2023 datasets.

Reconstruction Learning Analysis

The QRNN-based stacked autoencoder successfully learned compact latent representations of normal network traffic behavior. During training, normal traffic patterns generated low reconstruction errors, whereas malicious intrusion traffic produced significantly higher reconstruction deviations. The reconstruction learning process improved anomaly discrimination capability and enabled effective separation between benign and malicious communication behaviors. Temporal pooling operations further enhanced the capability of the QRNN architecture to learn coordinated attack sequences and long-range intrusion dependencies.

Impact of GAN-Assisted Minority Augmentation

The incorporation of WGAN-assisted minority augmentation significantly improved class balance across all intrusion datasets. Synthetic attack generation enhanced minority class representation and reduced model bias toward majority traffic categories. The generated intrusion samples preserved statistical similarity with original attack distributions while introducing sufficient diversity to improve deep learning generalization capability. The results presented in Table 4 demonstrate that GAN-assisted augmentation substantially improved minority attack detection performance. The augmentation strategy particularly improved recall and classification sensitivity for rare attack categories including: botnet intrusions, U2R attacks, R2L attacks, and IoT malware traffic

Ablation Study

An ablation study was performed to evaluate the contribution of each major component integrated within the proposed A-QRSAE framework. Different architectural configurations were evaluated by selectively removing individual modules. The ablation study clearly demonstrates that each integrated module contributes significantly toward overall intrusion detection performance. The removal of GAN augmentation reduced minority attack sensitivity, while eliminating Boruta optimization increased dimensional redundancy and reduced convergence efficiency. Similarly, excluding drift-aware adaptive learning reduced long-term stability under evolving network conditions. The complete integrated framework consistently achieved the best performance across all evaluation metrics.

Drift-Aware Adaptive Learning Performance

The drift-aware incremental learning module demonstrated strong adaptability under dynamically evolving traffic distributions. Statistical drift monitoring successfully identified distributional variations associated with emerging cyber threats and changing network communication patterns. Adaptive parameter updating significantly reduced long-term performance degradation and improved resilience against concept drift. The framework maintained stable intrusion detection capability without requiring complete retraining under evolving network environments. The results presented in Table 6 indicate that the proposed drift-aware adaptive learning strategy significantly improved long-term intrusion detection stability and reduced false positive rates under changing traffic distributions.

CONCLUSION

The increasing complexity of modern cyber threats and the rapid expansion of IoT, IIoT, cloud computing, and enterprise network infrastructures have significantly increased the demand for intelligent and adaptive intrusion detection systems capable of identifying both known and emerging attack behaviors. Conventional intrusion detection approaches frequently suffer from limitations associated with high-dimensional traffic features, severe class imbalance, evolving attack patterns, and reduced adaptability under dynamic cybersecurity environments. These limitations often result in degraded detection accuracy, poor minority attack recognition, and instability under real-world deployment conditions. To address these challenges, this research proposed an Adaptive Quasi-Recurrent Stacked Autoencoder (A-QRSAE) framework integrated with temporal pooling, Boruta-based feature optimization,

Wasserstein GAN-assisted minority attack augmentation, Bayesian hyperparameter optimization, and drift-aware adaptive learning for intelligent network intrusion detection. The architecture effectively combined temporal sequence learning, adaptive anomaly detection, and minority attack balancing within a unified deep learning architecture. The QRNN-based stacked autoencoder successfully captured long-range temporal intrusion dependencies while reducing computational complexity compared with conventional recurrent neural network architectures. The integration of temporal pooling further improved sequential representation learning and enabled efficient detection of coordinated attack behaviors and evolving malicious communication patterns.

Boruta feature optimization significantly reduced dimensional redundancy and improved computational efficiency by selecting highly relevant intrusion-related traffic attributes. The optimized feature subsets enhanced model convergence stability and improved anomaly discrimination capability during deep representation learning. The incorporation of Wasserstein GAN-assisted augmentation effectively addressed the severe class imbalance problem commonly observed in benchmark intrusion detection datasets. Synthetic minority attack generation substantially improved detection sensitivity for rare attack categories including user-to-root attacks, remote-to-local intrusions, botnet activities, and IoT malware traffic. The drift-aware adaptive learning module further enhanced the robustness of the proposed framework by enabling continuous adaptation under evolving network traffic distributions and concept drift conditions. Incremental learning and adaptive parameter updating allowed the framework to maintain stable intrusion detection capability without requiring complete retraining under changing cybersecurity environments. Experimental evaluation using NSL-KDD, UNSW-NB15, CICIDS2017, Edge-IIoTset, and CICIoT2023 datasets demonstrated that the proposed framework demonstrated superior intrusion detection capability compared with conventional machine learning and deep learning-based IDS approaches. The proposed A-QRSAE framework achieved high accuracy, precision, recall, F1-score, and AUC values while maintaining strong generalization capability across enterprise, cloud, IoT, and IIoT cybersecurity environments. The experimental findings validate that the integration of QRNN temporal learning, GAN-assisted minority augmentation, Boruta feature optimization, Bayesian hyperparameter optimization, and drift-aware adaptive learning significantly improves anomaly detection capability, minority attack sensitivity, computational scalability, and long-term adaptive stability. Overall, the proposed Adaptive Quasi-Recurrent Stacked Autoencoder framework provides a scalable, adaptive, and intelligent intrusion detection solution suitable for modern cybersecurity infrastructures. The framework establishes a strong foundation for future research in adaptive deep learning-based intrusion detection and next-generation intelligent cybersecurity systems

ABSTRACT

Ardhamatrika Basti is an Ayurvedic therapeutic enema primarily indicated for the management of Vata disorders and elimination of metabolic waste. Administered at half the dose of conventional Niruha Basti, it is traditionally used in conditions such as Vatarakta and is considered safe for regular administration. Among the five major Panchakarma procedures, Basti holds a pivotal role due to its systemic effects. Since Pitta and Kapha are functionally dependent on Vata, correction of Vata imbalance through Basti indirectly helps in regulating all three doshas. Classical texts such as Charaka Samhita describe Basti as central to disease management, with some authorities considering it equivalent to complete therapy. Unlike conventional enemas, Basti is understood to exert systemic physiological action. Ardhamatrika Basti, described in Vangasena and Chakradatta, is regarded as superior due to its rapid onset and therapeutic efficacy. The formulation contained Madhu (100 ml), Sneha (100 ml), Kalka (12 g), Kwathadravya (350 ml), and 1% Saindhava lavana. Accelerated stability studies, including organoleptic, physicochemical, microbial analysis, and HPTLC, showed no changes from 0 to 6 months. Stability and HPTLC studies confirmed the purity and stability of Ardhamatrika Basti, supporting further experimental and clinical evaluation.

Keywords: *Ardhamatrika Basti, Vatavyahi, Panchakarma, Vatarakta, Ayurved*

INTRODUCTION

Ayurveda, the ancient Indian system of medicine, emphasizes the maintenance of health through the balanced state of the Tridoshas—Vata, Pitta, and Kapha. Among the Panchakarma therapies, Basti (medicated enema) is regarded as the most effective modality for the management of Vata dosha, which governs movement and neurological functions in the body.[1] Based on the nature of ingredients and method of administration, Basti is classified into various types, among which Niruha (Asthapana) Basti consists of oil, honey, Kwatha (decoction), and Kalka (fine paste of medicinal drugs).[2] As these components are inherently immiscible, the classical texts prescribe a specific method of preparation to achieve and maintain a homogeneous mixture during administration, which is essential for therapeutic efficacy. Ardhamatrika Basti [3] described in classical treatises such as Chakradatta and Vangasena, is a modified form of Niruha Basti characterized by a reduced quantity of medicaments. It is considered superior due to its safety, rapid action, and wide therapeutic applicability, and can be administered without extensive preparatory procedures such as Snehana and Swedana, as well as without strict post-procedure regimens. It is suitable for Sukumara, elderly individuals, women, and patients apprehensive about conventional Basti therapy, and can be administered in all dosha predominance and Sannipata conditions. [4] Despite its therapeutic significance, the classical preparation of Basti is time-consuming, manpower-intensive, and requires precise preparation at each administration, posing practical challenges in contemporary clinical settings. To address these limitations, a ready-to-use formulation of Ardhamatrika Basti was developed. The present study aims to undertake pharmaceutical standardization and analytical characterization of this ready-to-use Ardhamatrika Basti to ensure its quality, stability, and suitability for clinical application.

MATERIALS AND METHODS

The present study was designed as a **pharmaceutical and analytical characterization study** of a ready-to-use formulation of Ardhamatrika Basti.

Preparation of Ready-to-Use ArdhamatrikaBasti

The ready-to-use Ardhamatrika Basti formulation was prepared at the Parul Institute of Ayurveda and Research (PIAR)pharmacy,Vadodara Gujarat following classical principles of Basti preparation. Initially, 100 ml of Madhu was taken in a clean mortar and triturated uniformly. Subsequently, 100 ml of Tila Taila was added gradually with continuous trituration to obtain a homogeneous mixture. After thorough mixing, 12 g of Kalka (A Pastw of Madanaphala and Shatapushpa) was incorporated and triturated until uniform dispersion was achieved. Finally, 350 ml of DashamoolaKwatha was added slowly with continuous mixing to maintain homogeneity. Amr salt (1%) was then added as a preservative, and the formulation was mixed thoroughly. The final product was transferred into sterile containers and stored under appropriate conditions for further analysis.

Pharmacognostical Evaluation

Pharmacognostic evaluation of the finished Ardhamatrika Basti formulation was carried out, including organoleptic examination such as colour, odour, taste, and appearance. Microscopic examination of the formulation was also performed to assess the presence of characteristic features of the constituent drugs. The analysis was conducted at the PIAR pharmacy and Vasu Research LaboratoryVadodara,Gujarat.

Physicochemical Analysis

Physicochemical parameters of the Ardhamatrika Basti formulation were evaluated using standard procedures. Parameters such as **specific gravity** and **density** were determined to assess the physical consistency and stability of the formulation.

High-Performance Thin-Layer Chromatography (HPTLC)

HPTLC analysis was carried out as per standard guidelines to develop a chromatographic fingerprint of the Ardhamatrika Basti formulation. The analysis was performed to assess chemical consistency and stability of the formulation over the study period.

Stability Study

An accelerated stability study was conducted to evaluate the stability of the ready-to-use Ardhamatrika Basti formulation. The formulation was assessed at predetermined intervals from **Day of preparation to 6th month** for organoleptic characteristics, physicochemical parameters, microbial load, and HPTLC profile to detect any changes over time.

OBSERVATION AND RESULT

Organoleptic Evaluation

The organoleptic characteristics of Ardhamatrika Basti remained unchanged throughout the study period. The formulation exhibited a light brown colour and characteristic odour at both 0 month and 6 months, indicating no visible physical deterioration during storage entitled in Table 1.

Physicochemical Analysis

Physicochemical parameters of the formulation at 0 and 6 months are presented in Table 1 The pH of the formulation showed a marginal decrease from 5.67 to 5.48**,** which remained within an acceptable acidic range and did not indicate instability. Total solid content remained almost constant (89.27% to 89.46%), suggesting good compositional stability. A slight increase in specific gravity **(**1.015 to 1.019**)** and minimal variation in viscosity (4.43 to 4.24cP**)** was observed, which were not considered pharmaceutically significant. These findings indicate that the formulation maintained physical and chemical consistency over the 6-month storage period.

Microbiological Analysis

Microbiological evaluation revealed a marked improvement in microbial quality over the study period. The total microbial plate count reduced from 3449 cfu/g at 0 month to <10 cfu/g at 6months**,** while yeast and mould counts, initially present at 720 cfu/g, were absent at 6 months. Pathogenic organisms including *Staphylococcus aureus*, *Salmonella* spp., *Pseudomonas aeruginosa*, and *Escherichia coli* were absent at both time points, confirming the microbial safety of the formulation.

HPTLC Fingerprint Analysis

HPTLC fingerprinting of Ardhamatrika Basti at 0 and 6 months demonstrated as showsn in figure 1 are identical chromatographic profiles at 254 nm, 366 nm, and 540 nm. At 254 nm, nine spots with identical Rf values (0.17–0.82) were observed in both samples. Similarly, at 366 nm and 540 nm, the number of spots and their respective Rf values remained unchanged between the two time points.

The overlapping chromatographic fingerprints indicate no qualitative changes in chemicalconstituents**,** confirming the chemical stability and consistency of the formulation during the storage period.

DISCUSSION

The present study aimed at the development and analytical evaluation of an instant mix Ardhamatrika Basti using a standardized homogeneous preparation method. In this formulation, Makshika (Madhu), Sneha, Kalka, and Kwathadravya were combined systematically to ensure uniform mixing of immiscible components, followed by the addition of 0.1% Amr salt as a preservative.[5] This approach was adopted to address practical limitations associated with classical Basti preparation, which requires repeated fresh preparation, skilled manpower, and strict procedural

precision at each administration. Analytical evaluation revealed that key physicochemical parameters, including pH, viscosity, and total solid content of the instant mix Ardhamatrika Basti, were comparable to those of the routinely prepared classical formulation. These findings suggest that the instant mix retains essential pharmaceutical characteristics required for safe administration. Accelerated stability testing further demonstrated a shelf life of six months, with no significant changes observed in organoleptic, physicochemical, microbiological, or HPTLC parameters. Identical chromatographic fingerprints at 0 and 6 months confirmed the chemical stability and consistency of the formulation. From a practical perspective, the development of a ready-to-use Ardhamatrika Basti offers significant advantages for routine clinical practice. The instant mix formulation reduces preparation time, minimizes the need for trained manpower, and eliminates variability associated with repeated bedside preparation. This facilitates ease of administration in outpatient, inpatient, and institutional settings, thereby improving feasibility and standardization of Basti therapy in day-to-day practice. Classical Ayurvedic texts such as Vangasena and Chakradatta emphasize the suitability of Ardhamatrika Basti for repeated and even daily administration, particularly in chronic disorders, without compromising safety. The instant mix formulation aligns with these classical indications while adapting the therapy to contemporary healthcare environments. By simplifying preparation without altering the fundamental composition, this approach serves as a bridge between classical Basti principles and modern clinical workflow. Despite its wide classical indications, systematic scientific evaluation of Ardhamatrika Basti has remained limited. The present study contributes by providing pharmaceutical standardization, analytical validation, and stability data for a ready-to-use formulation. This lays a foundation for future clinical trials and facilitates broader acceptance of Basti therapy within integrative and evidence-based healthcare systems.

CONCLUSION

The instant mix Ardhamatrika Basti developed in this study demonstrated satisfactory analytical stability and quality over a six-month period. The standardized homogeneous preparation method reduces preparation time and manpower requirements, making the formulation easy to use and suitable for routine clinical practice. The findings support the feasibility of this ready-to-use formulation and provide a basis for further clinical evaluation.

ABSTRACT

The air in the three main cities of Jharkhand- Ranchi (the state capital), Dhanbad (a coal belt town), and Jamshedpur (a steel town)- is polluted in different ways. Moreover, the polluted state of air reveals two different types of anthropogenic emission regimes, but both are disturbing at the same time. The study combines two years (2022–2023) of primary field observations in five land-use zones of Ranchi with secondary published data from CPCB, JSPCB and peer-reviewed papers for Dhanbad and Jamshedpur to develop the first systematic tri-city comparative air quality assessment for the region. The monthly concentrations of PM_{10}, $PM_{2.5}$, SO_2 and NO_2 alongwith eight meteorological parameters measured at Ranchi have been interpreted through a comparative framework placing the pollution at Ranchi alongwith Dhanbad, a coal dominated city and Jamshedpur, an industrially intensive city. Continuous monitoring of $PM_{2.5}$ at Kantatoli road traffic intersection, Ranchi shows unregulated use of roads and construction of temporary and permanent infrastructures with non-measured impacts on air pollution. In 2022, $PM_{2.5}$ reached a level at an annual mean of 111.44 μg/m³, which is 2.79 times the National Ambient Air Quality Standards (NAAQS) of India and 22.3 times the WHO 2021 guideline value of 5 μg/m³. PM_{10} at all five sites exceeded NAAQS during both the years. The NAAQS permissible limit for NO2 at Kantatoli during winter-inversion months for 24 hr is approaching at 5.9% per annum increase. Out of the three cities, Dhanbad exhibits the maximum burden of coal dust and SO_2 due to open-cast mining and thermal power activities, while Jamshedpur shows high particulate and metallic aerosol loading due to integrated steel-making. In Ranchi, with not much heavy industrial presence, the NO_2 value was highest due to the rapidly growing vehicular population. Between 2022 and 2023, Ranchi, urban sites experienced a continuous inter-annual deterioration trend despite greater monsoon rainfall in 2023. It is clear that the emissions growth is the primary driver behind this. The air quality buffering capacity of intact forest cover has

been quantified and NAAQS and WHO compliance of all the three cities has been evaluated along with city-specific emission profiles policy prescriptions.

INTRODUCTION

Ambient air pollution contributes to a staggering 1.67 million premature deaths in 2019 in India or nearly 18 per cent of total deaths in India. Gaubert et al's (2020) estimate might be the tip of the iceberg as more severe estimates exist.Long-term exposure to fine particulate matter ($PM_{2.5}$) and other gaseous pollutants causes various health impacts including chromosome damage (deoxyribonucleic acid or DNA damage and genetic mutations) and cardiovascular disease, among many others. According to Lelieveld et al. and Landrigan et al., children and elderly are most affected. The launch of the NCAP scheme in 2019 by India and its target of the 20%-30% reduction of PM2.5 and PM10 concentration by 2024 in 122 non-attainment cities shows the seriousness of the regulations. Implementation shortcomings are serious especially in any cities not mentioned above which are not CPCB. Ranchi, Dhanbad, and Jamshedpur the three prime cities of Jharkhand host industrial and infrastructural activities of national economic importance but the ambient air quality literature of the region is sporadic, methodologically inconsistent and comparative. Dhanbad city which is in the Jharia coalfield and known as the coal capital of India has coking coal. It is one of the largest coalfields in Asia. Continuous dust, SO_2 and volatile organic compound (VOC) emissions from the opencast mining, underground fire, washeries and coal-based thermal power at this place are chronic (Singh et al., 2021; Patra et al., 2016). The headquarters of Tata Steel's flagship integrated steel plant, Jamshedpur has a clear metallic chemical signature. This suspended particulate matter has iron oxide, manganese, chromium, and other coke oven by-products which contribute to the known carcinogen polycyclic aromatic hydrocarbons (PAHs) in the urban airshed (Ghosh et al. (2019); Srivastava & Jain (2020)). The capital of the state, Ranchi does not host that kind of heavy industry but the vehicular fleet, construction activity, and mixed-use densifying are all growing at a decent clip that is generating out here a pollution profile that is different from neighbouring parts of India. Ranchi is dealing with pollution because of heavy traffic.

Multiple studies in the scientific literature show an increasing focus on Indian urban air quality, especially NCR Delhi, Indo-Gangetic Plain megacities, and coastal metropolitan cities. Located in Eastern India, the collection of small towns Jharkhand, Odisha and Chhattisgarh is represented by a modest work. In 2020, Kumar and colleagues conducted a research on $PM_{2.5}$ source profiles in six Indian urban locations excluding Jharkhand. Gupta and others in 2021 documented PM variability seasonally in urban-industrial sites of Jharkhand at only one monitoring station. The objective of this study is to fill a knowledge gap that exists due to the absence of a multi-city comparative framework with a standardized methodology and contemporaneous weather characterization.

Three cities offer a unique natural experiment in identifying emission sources. By studying a traffic-urbanization dominant city, Ranchi, a coal extraction dominant city, Dhanbad and a metallurgical-industrial dominant city, Jamshedpur, the study intends to identify how the differences in source sector reflect differences in pollutant composition, seasonality and exposure to health effects. These cities belong to the same biogeographic region, same monsoonal system and same regulatory framework. Such comparison will have high importance for designing of targeted policies under NCAP, which require city-wise emission characterization instead of a common control intervention, action plans.

Research Objectives

- Assess the monthly and annual concentrations of PM_{10}, $PM_{2.5}$, SO_2, and NO_2 across five land-use zones of Ranchi for the year 2022–2023 using primary field measurements.

- Create a comparative framework of air quality by integrating primary data from Ranchi with published secondary data from the monitoring networks of CPCB/JSPCB and peer-reviewed literature from Dhanbad and Jamshedpur.
- The goal is to identify the dominant anthropogenic emission sources causing spatial heterogeneity within Ranchi and sectoral difference across the three cities.
- This study aims to assess compliance with NAAQS (2009) and WHO Air Quality Guideline (2021) at all three cities, quantify magnitude and trend of exceedances
- Examine the meteorological factors like temperature, rainfall, humidity, wind speed and direction, solar radiation, and atmospheric pressure affecting the dispersion and accumulation of pollutants.
- Public health risk exposure characterization and formulation of pan-city differentiated evidence-based policy recommendations in pursuit of India's NCAP objectives.

New Features and Research Contribution

This research has important scientific contributions. To begin with, it offers the most extensive primary multi-parameter air quality dataset ever compiled for Ranchi to date over 24 months from five land-use zones with a temporal and spatial depth that is lacking in any previous literature from Jharkhand. Secondly, It builds a comparative tri-city framework of the three largest cities of Jharkhand which has not so far been published in any SCI-indexed journal, to the best knowledge of the authors. This state-of-the-art report expands the knowledge base on inter-annual variability in air quality, highlighting that Ranchi's air quality is adversely impacted by emission growth rather than meteorological variation. Use of the 2023 monsoon intensity as a natural control variable is significant and helps further our understanding of this problem. In addition, it provides quantified evidence for the air quality co-benefit of intact urban forest cover data that can be directly leveraged to inform green infrastructure investment decisions and decision-making around NCAP implementation. The research investigation fills a documented gap in the eastern Indian Tier–2 city air quality literature and provides the scientific baseline needed to monitor the effectiveness of future policy interventions across Jharkhand.

LITERATURE REVIEW

Air Pollution in Indian Tier-2 Cities and Eastern India

The course of research on Indian air quality has been disproportionately influenced by the crises observable in National Capital Region Delhi, where $PM_{2.5}$ concentrations commonly go above 300 μg/m³ in winter episodes. (Mahato et al., 2020; Guo et al., 2020). Yet, data from CPCB's National Ambient Air Quality Monitoring Programme (NAMP) reveals that exceedances in the NAAQS standards are much more geographically widespread than the Delhi narrative suggests. In their 2019 study Balakrishnan et al. used satellite-derived $PM_{2.5}$ data to estimate that more than 660 million Indian live in places where annual $PM_{2.5}$ concentration exceed WHO guideline. Moreover, huge populations from Tier-2 and Tier-3 cities face $PM_{2.5}$ exposure level that are comparable to exceed those found in megacities. The monitoring infrastructure shortcoming in secondary Indian cities is a barrier to evidence-based action Singh et al. (2022) argue that the existing NAMP networks monitor less than 30% of exposure of India's urban population. The industrial geography of eastern India, which is mainly based on coal, steel, aluminum and heavy engineering in Jharkhand, Odisha and Chhattisgarh, generates pollution characteristics which are quite different from the crop burning and traffic of Indo-Gangetic Plain studies. Patra et al. (2016) undertook one of the early systematic evaluations of air quality in a coal mine area in the belt region of Jharia coalfield, and levels of PM_{10} were above 400 μg/m³ in areas near coal loading. Senior researchers Srivastava and Jain wrote a research work to identify the growth of particulate matter in Jamshedpur. In this research work, it has been stated that the major crustal and industrial trace elements of Srivastava & Jain are iron oxide, silica and aluminum. According to Ghosh et al. (2019), benzene and PAH concentrations were elevated in the vicinity of coke oven units of the industrial belt of eastern India. The studies point to the fact that industrial cities of East India face a qualitatively different type of pollution than elsewhere in the country.

Weather factors of urban pollution in subtropical India.

India's monsoon system is the primary meteorological factor influencing subcontinent-wide variations in the seasonality of urban air quality. Wet scavenging is the removal of pollutants by rain. During the Southwest Monsoon (June – September), a substantial fraction of both particulate matter and soluble gaseous pollutants are removed by wet scavenging. As SO_2 dissolves readily in rain, sulphurous and sulphuric acid are formed (Parashar et al., 2016). This happens due to the hygroscopic growth and below-cloud wet scavenging of accumulation-mode particles. Reduced mixing heights of boundary layer during winter (November to January) due to radiative cooling at the surface and weak convective circulation create the optimum conditions for maximum build-up of pollutants (Dey & Tripathi, 2007). The plateau regions of India, at latitudes of roughly 23° to 40°N, experience seasonal temperature inversions which trap emissions within shallow atmospheric layers. This phenomenon increases exposure levels, with the worst exposures occurring during the season when emissions are the highest (Kumar et al. 2016). The urban heat island (UHI) effect increases the dynamics in built areas. Research by Mohan et al. (2012) established the UHI intensities in Indian cities to be in the range of 2 – 5°C. This study also highlighted the role of the UHI-induced secondary circulations in mixing. This mixing can lead to the reduction of pollution concentrations in certain cases. However, it also gives rise to local convergence zones that enhance the pollutant concentrations downwind the area of strong flux of heat. In Indian monsoon circulation, the change in the wind direction from northerly in winter to south westerly in the monsoon impacts cross-city pollutant transport pathways in specific cities. This is especially true for the geographically proximate Ranchi–Dhanbad–Jamshedpur cluster. Here, industrial emissions from one city can impact the airshed of another city under specific wind regime as suggested by Yadav et al. (2019).

Vehicular Emissions and Traffic-Derived Pollution

The Indian traffic corridors' main source of NO_2, fine particulate matter especially its elemental carbon and organic carbon fractions and carbon monoxide is vehicular exhaust (Pant & Harrison, 2013; Goel & Kumar, 2015). Vehicle fleet in India has been increasing at about 8-12% annually in Tier-2 cities. For instance, two-wheelers have 60-70% share of the fleet mix in the cities such as Ranchi (CPCB 2021). These two-wheelers are mainly older carbureted two-wheelers with poor emission characteristic. Following the implementation of new emission rules BS-VI in April 2020, new vehicles now emit less NOx and particulates per vehicle. However, the vast legacy fleet of pre-BS-VI vehicles continues to be the leader of actual on-road emissions. Anand et al. (2021) estimated that greater than 60% of vehicular $PM_{2.5}$ emissions from Indian Tier-2 cities come from pre-BS-IV cars which form less than 35% of the fleet. Patterns of traffic congestion during the morning and evening. 07:00 – 10:00 hours and 17:00-20:00 hours, respectively, cause episodic concentration events. 24-hour NAAQS limits may be breached in rush hours only. They may comply with the National Ambient Air Quality Standards (NAAQS) standards on a daily or monthly average level.

Pollution through coal mining and thermal power at Dhanbad

Dhanbad occupies a central position in the Jharia coalfield. It has an estimated 3.5 billion tonnes of recoverable coking coal. Moreover, it has more than 100 operational collieries, 9 coal washeries and few coal-based thermal power stations (within 50-km radius) (Central Mine Planning and Design Institute, 2021). The Bokaro Thermal Power Station, Chandrapura Thermal Power Station, and the Tenughat thermal power station located in Dhanbad–Bokaro urban cluster emit thousands of tonnes of SO_2, fly ash every year. The activities of blasting, loading and hauling in open-cast coal mining cause high-intensity fugitive dust events. Such operations can increase PM_{10} concentrations to a level higher than 500 $\mu g/m^3$ in the proximate community of the mine (Patra et al. 2016). For more than a century, underground coal seam fires have been burning in the Jharia coalfield and they represent an essentially uncontrolled source of emission of CO, SO_2 and particulate carbon that is unique thus far in India (Singh et al., 2021). According to NAMP Data of CPCB, Dhanbad has been found to have SO_2 concentrations many times dating back 2012, close to, and exceeding NAAQS limits. Dhanbad, a highly polluted area, shows a sharp contrast with Ranchi and Jamshedpur. The concentrations of SO_2 are compliant with NAAQS in Ranchi and Jamshedpur.

Steel industry and metalurgical pollution in Jamshedpur

Tata Steel's integrated plant in Jamshedpur is one of Asia's biggest and oldest integrated plants with an installed capacity of more than 10 million tonnes per annum. Further, it is an emission complex consisting of sintering, blast furnace, basic oxygen furnace steelmaking, coke ovens, rolling mills and raw material handling. Each process unit has its own signature of pollutants. There are SO2, NOx, and metallic particulates from the sinter plants; CO and fine iron oxide particulates from the blast furnaces; PAHs, benzene, and H2S from the coke ovens; and fugitive iron ore and coking coal dust from raw material handling (Ghosh et al., 2019; Srivastava & Jain, 2020). The water-soluble fraction of air PM2.5 from Jamshedpur shows higher iron and heavy metals (Mn, Cr, Pb) and lower organic carbon to elemental carbon ratios as compared to those from Ranchi and Dhanbad, indicating metallurgical source like steel production. Tata Steel has been at the forefront of environmental management for many decades. Its Meghalaya plant has a well-made use of perchlorate and all other necessary controls. Moreover, such massive investments, as well as the cumulative compliance status (JSPCB, 2022), pollution control keeps Jamshedpur measured NAAQS compliance status better than what its industrial intensity would suggest. Nevertheless, with recent fleet growth, NO_2 conformity reveals a more complex picture.

Health Burden of $PM_{2.5}$ in South Asian Cities

In recent years, a lot of epidemiological evidence has come out linking long-term $PM_{2.5}$ exposure to increased mortality and morbidity in South Asia. According to Balakrishnan et al. (2019), $PM_{2.5}$ exposure was responsible for 980,000 deaths early in India in 2017. The major disease endpoints were chronic obstructive pulmonary disease (COPD) and ischemic heart disease. The World Health Organization (WHO) Comparative Risk Assessment framework indicates that there is a 6–7% rise in all-cause mortality with every 10 μg/m³ increase in long-term $PM_{2.5}$ exposure (WHO, 2021). During the first three years of life, when the lungs are still developing, children develop respiratory diseases as a result of exposure to PM2.5 pollution. If the level of PM2.5 pollutants exceeds 35 μg/m³, research has shown measurable deficits in the development of lung function, which continue to exist through adulthood. (Landrigan et al, 2018) The disease burden attributed to these dose- response relationships for cities in Jharkhand, where annual $PM_{2.5}$ means are in the range of 60–110 μg/m³ or more, is large and unquantified in any city-specific health impact assessment.

Study Area Description

Ranchi — The Rapidly Urbanizing State Capital

The Chota Nagpur Plateau is a tectonically stable crystalline basement. As such, it is a part of the Peninsular Shield of India. It is located in Ranchi (23°N, 85°E; elevation 651 m AMSL). The average elevation of the plateau produces a humid subtropical climate (KöppenCwa) cooler than the neighbouring Gangetic plains. The mean annual temperature of the region is around 24 °C. Annual rainfall is about 1,400–1,500 mm and concentrated in the Southwest Monsoon (June–September). Since its designation as the capital of the newly formed state of Jharkhand in 2000, Ranchi has been witnessing continuous demographic growth from approximately 0.85 million in 2001 to more than 1.4 million in the metropolitan area in 2023. Further it has witnessed unplanned extension of the city, significant infrastructure construction and exponential growth of the vehicular fleet. The focus of industrial activity is in the Tupudana, Namkum and Tatisilwai corridors where foundries, engineering works and small to medium manufacturing units are located. The busy commercial areas of Kantatoli, Albert Ekka Chowk, and Lalpur are the city's most heavily trafficked zones, which experience high-intensity pulses of mobile-source emissions due to congested vehicles as shown in map in Figure 1 below.

Dhanbad — The Coal Capital

Located in eastern Jharkhand at a distance of 130 km northeast of Ranchi is Dhanbad (23.8°N, 86.4°E; elevation 227 m AMSL). Dhanbad, located in Jharkhand, India, is called the coal capital of India. It is situated on the Jharia coalfield which contains the largest deposits of prime coking coal in India. The economy of the city, which has a population of around 1.2 million (Urban Agglomeration), is dominated by coal mining and coal processing, thermal power generation and auxiliary activities. Jharia coalfield has over 100 running collieries operated mainly by Bharat Coking Coal Limited (BCCCL), a Coal India Limited subsidiary with many illegal miners operating in the area Close

proximity to Bokaro Steel City and several thermal power stations (like Chandrapura TPS, Bokaro TPS, Tenughat TPS) has created a multi-source airshed extending much beyond the administrative city limits. Dhanbad's lower elevation as compared to Ranchi and location in a more open terrain results in somewhat less trapping of terrain-driven pollution. Nevertheless, summer temperature inversions do create episodic accumulation events.

Jamshedpur — The Planned Steel City

Jamshedpur (22.8°N, 86.2°E; elevation 135 m AMSL) was established as a planned industrial township by Tata Steel (then Tata Iron and Steel Company) in 1907. It is located about 160 km south of Ranchi. Tata Steel Jamshedpur plant, which sprawls over 3000 acres, is one of the largest integrated steel production centres in Asia producing more than 10 million tonnes of crude steel. The metallurgical industrial complex of the city, comprising of blast furnaces, coke ovens, sinter plants, rolling mills, and extensive raw material (iron ore and coal) handling facilities, generates fugitive dust continuously. In addition to industrial emissions, Jamshedpur's population of about 1.3 million in the urban agglomeration has generated increasing vehicular traffic particularly in commercial areas beyond the controlled Tata Steel township boundary. The industrial environmental management system of Jamshedpur is relatively more sophisticated and provides better continuous emission monitoring data at main point sources as compared to Dhanbad's spread-out mining.

Ranchi Primary Monitoring Site Network

Five monitoring sites were selected in Ranchi using stratified purposive sampling to reflect the entire range of land-use conditions. These were Tupudana Industrial Area (Site 1: 23°15′56″N, 85°18′10″E), Kantatoli Traffic Hub (Site 2: 23°21′52″N, 85°20′43″E), Harmu Residential Zone (Site 3: 23°21′12″N, 85°18′30″E), Kanke Agricultural Area (Site 4: 23°27′19″N, 85°19′19″E) and Birsa Zoological Park Eco-Sensitive Area (Site 5: 23°27′48″N, 85°27′24″E). As this stratification allows for gradient analysis covering urban to rural and industry to green transects, it captures the entire range of emission environments in the city (Table 1).

MATERIALS AND METHODS

Primary Monitoring Methodology — Ranchi

Using calibrated high-volume gravimetric air samplers that operate on USEPA equivalent methods (as per CFR 40 Part 50, Appendix J and L), particulate matter (PM_{10} and $PM_{2.5}$) was measured through 24-hour integrated sampling at each site once every month. Weight of the filter samples was taken twice (before and after the sampling) on an analytical balance (sensitivity ±0.01 mg) in a temperature and humidity controlled environment. SO_2 was determined by West-Gaeke modified pararosaniline colourimetric method (IS: 5182 Part 2) and NO_2 was quantified by modified Jacob-Hochheiser sodium arsenitecolouri metric method (IS: 5182 Part 6), which are methods prescribed by CPCB SOPs. Weather stations, or automatic weather stations (AWS), are used to measure various meteorological parameters. These AWS were installed either at the site or in close proximity (within 10m) of the air quality monitoring stations. The complete period of the study was from January 2022 to December 2023, which generated 12 monthly mean observations from each parameter at each site.

Secondary Data Sources — Dhanbad and Jamshedpur

The secondary air quality data for Dhanbad and Jamshedpur has been compiled from the following published and institutional sources: (i) the annual reports of the NAMP of CPCB for the Jharkhand monitoring stations at Dhanbad and Jamshedpur; (ii) the Annual Environmental Status Reports and Air Quality Monitoring Reports of JSPCB for the years 2019–2023; (iii) the NCAP progress reports of the Jharkhand non-attainment cities; (iv) peer-reviewed studies published in journals from ScienceDirect, Springer and Elsevier containing Dhanbad and Jamshedpur air quality; and (v) satellite-derived PM2.5 datasets from MERRA-2 and GBD environmental pollution datasets. When multiple secondary sources gave overlapping data, which was available for the same year and the same station value, range values were given with the source citation and means were computed if the source value was three and above.

Statistical Methods

The arithmetic mean, standard deviation (SD) and standard error of the mean (SE = SD/square root of n; where n = 12 monthly observations) of all primary Ranchi data was worked out. SD quantifies month-to-month variation for each year, while SE indicates the accuracy of the year's mean estimate. To compare the various pollutants and the meteorological parameters at each site in Ranchi (temperature, rainfall, humidity, wind speed), Pearson correlation coefficients were determined for the individual pollutants. They were statistically assessed at $p < 0.05$ using a two-tailed t-test. Seasonal analysis was conducted on monsoon (June–September) and non-monsoon (October–May) period. The $PM_{2.5}/PM_{10}$ ratios were calculated for each site as a diagnostic of source attribution. Both absolute ($\mu g/m^3$) annual changes and proportional changes were expressed between 2022 and 2023.

Reference Framework for Regulation

All the concentrations which are measured are compared to annual and 24hour average of India's National Ambient Air Quality Standards (NAAQS, 2009) and WHO Global Air Quality Guidelines (2021) annual reference values (Table 2).

Meteorological Characterization of Ranchi

Temperature and Urban Heat Island

Temperature data across Ranchi's five sites shows the four-phase seasonal architecture of the humid subtropical Chota Nagpur Plateau cool dry winter (January–February: 14.5–19.5°C) sharp pre-monsoon heat peak (April–May: 26.5–32°C) thermally moderated monsoon period (June–September: 24–29°C) post-monsoon transition (October–November: 20–25°C). Kantatoli (Site 2) recorded the maximum temperature which reached 31.5 °C in May 2023. This may be due to the effect of urban heat island, high impervious surface fractj and low albedo of road surface along with heat waste from vehicles. Birsa Zoological Park (Site 5) recorded temperatures 3-4 °C lower than those at Kantatoli in summers, indicating the forest canopy incorporates the ability of closed forests to buffer against temperature through evapo transpiration (Table 3). When comparing the months of 2023 with corresponding months of 2022, all sites show a consistent warming signal of 0.2–0.7°C, which is directionally consistent with documented trends of UHI intensification in fast-growing Indian cities.

Rainfall, Humidity, Wind Speed, and Solar Radiation

Rainfall during the monsoon season dominates the annual water cycle at all sites and contributes 75–80% of annual precipitation, i.e., during the months of June to September. In July 2023, rainfall was greater than the rainfall in 2022 universally over Ranchi. Kantatoli got 348 mm of rain (335 mm in 2022, +3.9%), Birsa Zoo 350 mm (340 mm, +2.9%), Harmu 345 mm (330 mm, +4.5%). Annual totals at all sites are higher by 6.5–7.3% from 2022 to 2023. This persistent higher rainfall in 2023 is scientifically important, as it sets up a natural experiment in which a higher wet scavenging efficiency should have produced lower 2023 pollutant concentrations compared to 2022. However, the opposite was observed at the urban sites, isolating emission growth as the controlling factor. The peak relative humidity from July to August was 85-91 %. Wind speed showed a seasonal trend. The wind is more in pre-monsoon months (12–15 km/h in May–June) due to thermal convective gradients. The wind becomes low (05–7 km/h) during calm winter months. Over the months of December to February, the wind direction were mostly from the north. This had changed to south westerly during the monsoon. This change in wind direction is a direct expression of the reversal of the Indian monsoon circulation. The cold winds from the north at winter time have the potential for cross-site pollutant transport from the Tupudana industrial zone northwards towards southern residential areas. Solar radiation was high (240–260 W/m^2) during April–May at urban sites. It was lower (170–250 W/m^2) at Birsa Zoo due to canopy light interception.

Air Quality Results and Analysis — Ranchi

Particulate Matter PM_{10}

The concentration of PM_{10} has become more than the annual NAAQS standard of 60 $\mu g/m^3$ at all the five Ranchi sites in both years. This suggests that the PM pollution is not location-specific but a systemic one. The mean annual values ranged from 97.92 $\mu g/m^3$ (Birsa Zoo, 2020) to 109.62 $\mu g/m^3$ (Tupudana, 2020) which was 163% to 183% of NAAQS

limit and 553% to 631% of WHO limit (Table 4). The small standard deviations (0.98–2.38 μg/m³) imply that the month-to-month concentrations of PM_{10} are relatively stable, which is quite unexpected due to the natural washout effect of the monsoon. Month-to-month data makes it evident that indeed monsoon months do show the lower range of values of PM_{10} (for instance, Tupudana August 2022 PM_{10} 106.5 versus January 2022 PM_{10} 114.2 μg/m³). But the absolute magnitude of reduction is small compared to a high baseline. By construction activities, unpaved roads and dry soil, resuspension of crustal dust is causing a significant contribution to PM_{10} of Ranchi since crustal sources are washed away by wet deposition, which is much less as compared to combustion-generated aerosols.

Fine Particulate Matter $PM_{2.5}$ — The Critical Parameter

The $PM_{2.5}$ readings indicate the most disturbing air quality situation in the data set. In 2022, the annual mean at the Kantatoli Traffic Hub (Site 2) was 111.44 μg/m³, which was 279% of the NAAQS limit and a remarkable 2,229% of the WHO 2021 guideline value of 5 μg/m³. Tupudana Industrial Area (Site 1) recorded 99.34 μg/m³ which is 148% higher than NAAQS. The annual mean at even the cleanest site in the network, Birsa Zoological Park (Site 5), which is also the reference forest ecosystem, was 62.48 μg/m³, i.e., 56% above NAAQS. The findings suggest that regional background $PM_{2.5}$ loading thermal over the Chota Nagpur Plateau itself is too high to be health protective. This elevated loading which reflects the cumulative effect of regional coal burning, long-distance transport from the Pollution pool of the Indo-Gangetic Plain and biomass burning emissions from surrounding rural Hinterland. The relationship between $PM_{2.5}$ and PM_{10} indicates the source. At Sites 1 and 2, the value remained above 0.90 for 2022. This indicates that over 90 % of total particulate mass originates from combustion source fine particles. By international standards, this is exceptionally high (normal urban backgrounds typically range 0.50–0.70). They point to dominance of vehicular exhaust and industrial combustion aerosols. When measurements were taken at Site 5 (Birsa Zoo), the ratio dropped to around 0.64 which is more in line with background conditions. This is the case where a proportional mixture of crustal dust and other source contributions could be present. Seasonally, $PM_{2.5}$ was more variable than PM_{10} at all sites. At Kantatoli, in the month of August which is the monsoon minimum it was 101.5 μg/m³. Moreover, in the month of September it was 116.4 μg/m³. 116.4 μg/m³ is after-monsoon that is maximum due to several reasons including open burning and atmosphere imparting (fast) drying initiation. In 2023, $PM_{2.5}$ at Tupudana was 7–10 μg/m³ higher in non-monsoon months than in 2022. This figure translates to 8-10% yearly worsening.

Sulfur Dioxide (SO_2)

At all Ranchi sites, SO_2 levels remained below the NAAQS annual (50 μg/m³) and 24-hour (80 μg/m³) limits in both years. This is currently the only pollutant in this dataset that is within limits (Table 6). Notable is the inter-annual trend: the year-on-year (YoY) increase of Tupudana was 11.2 per cent (26.76 to 29.76 μg/m³), which was the largest YoY increase of any pollutant-site combination. SO_2 is the most seasonal pollutant we measure. In December 2022, the monthly mean of sulphur dioxide (SO_2) at Tupudana (Site 1) was 34.86 μg/m³ while the monthly minimum was recorded at 11.22 μg/m³ in August. The seasonal range of approximately three times in concentrations is due to three factors operating together S. First, the emissions from various sources in the area get trapped in a shallow boundary layer under thermal inversions during winters. Second, there is an increase in domestic burning of biomass for space heating (November–January). Third, there is the absence of wet scavenging during monsoons which otherwise removes SO_2 from the gas phase efficiently. In all sites, December values were higher than in 2022 in 2023 (Site 1: 36.86 vs. 34.86 μg/m³), as it appears to rise further.

Nitrogen Dioxide (NO_2)

In the dataset (Table 7), NO_2 poses the highest risk of a non-compliance. Kantatoli (Site 2) recorded monthly means of 69.17 μg/m³ in December, 2022 and 73.22 μg/m³ in December, 2023. These concentrations are much above the NAAQS annual standard of 40 μg/m³. The monthly means were approaching the NAAQS 24-hour standard of 80 μg/m³. Because these values are monthly means, instantaneous hourly peak concentrations during morning and evening rush hours in winter will almost certainly exceed the 24-hour limit on individual days. Tupudana (Site 1) showed a similar high value of 63.40 μg/m³ in December 2022, which rose to 67.11 μg/m³ in December 2023. At both sites there was a year on year increase of 5.9% in peak month NO_2. If the vehicle population of Ranchi keeps

increasing at the rate of 8-12% per year, Kantatoli is likely to exceed the NAAQS 24-hour standard as a monthly mean in 3-5 years under business as usual scenario. The seasonal cycle of NO_2 emerges from competing processes across the seasons. Primary emission accumulation occurs in winter when atmospheric mixing is lower and traffic activity is sustained. Photochemical transformation occurs in summer when NO_2 is consumed through the $NO_2 + h\nu \rightarrow NO + O$ reaction that initiates ozone. The strong winter dominance confirms that the effect of primary emissions is stronger than the impact of the photochemical sink during the cold months of Ranchi's. Kantatoli's monsoon minima (24.39 μg/m³ in July 2022) reflect enhanced atmospheric mixing and reduced traffic during heavy rains and wet removal of soluble nitrogen species.

Comparative Air Quality Analysis: Ranchi, Dhanbad, and Jamshedpur

Comparative PM_{10} and $PM_{2.5}$ Profiles

The variation in PM concentration profiles across three cities despite their similar seasonal and regulatory structure (Table 8) controlled by the monsoon. Dhanbad regularly records the highest levels of PM_{10} of the three cities, while CPCB NAMP as per data reports annual means of 130–180 μg/m³ at mining-adjacent stations in recent years exceedances of 217–300% of NAAQS (CPCB NAMP, 2021–2023; Singh et al., 2021). In Dhanbad, the PM loading is dominated by coarser particles. Therefore, the PM2.5/PM10 ratio at the monitoring stations is usually less than 0.55–0.65. This shows that open-cast activities and mine haul roads emit a considerable amount of crustal coal dust. The chemical composition of this dust differs from the fine particles. These fine particles are dominated by combustion which has a much heavier contribution in case of traffic sites at Ranchi. In Jamshedpur, the annual PM_{10} means observed at the CPCB-measured stations range from 90–140 μg/m³, reflecting mixed contributions from steel plant fugitive dust and raw material handling, along with growing vehicular traffic (JSPCB, 2022). The $PM_{2.5}$ and PM_{10} ratios at industrial sites in Jamshedpur are in the intermediate range (0.60–0.75). This indicates the presence of metallic industrial particulates and combustion aerosol in these sites.

SO_2 as the Dhanbad Signature Pollutant

The most significant differentiating pollutant parameter in the three cities is SO_2. The SO_2 burden in Ranchi is moderate and presently NAAQS-compliant. Small foundries, domestic burning of biomass, and limited use of fossil fuels in industries are the reasons responsible for this status. The elevated concentration of SO_2 in Jamshedpur is due to the sinter plant and coke oven operations in the Tata Steel complex. The concentration has nearly reached NAAQS limits during peak production and unfavourable meteorological conditions. The SO_2 profile of Dhanbad is qualitatively different. The burning of coal seam fires continuously at the surface results in uncontrolled emissions of sulfur dioxide which is not a part of any emission inventory and not controlled by any stack based control technology. During winter temperature inversions, the SO_2 from mine fires, thermal power stations, and coal combustion by industry and domestic users can build up at level concentrations that may violate NAAQS mainly by two processes near the mines (Singh et al., 2021). The spatial heterogeneity of SO_2 field at Dhanbad, where SO_2 concentrations are very high near mine fires and decreases to a low value at the central urban monitoring station, implies that the aggregated CPCB NAMP station data under estimates community exposure of populations adjacent to mines.

NO_2 as the Ranchi Signature Pollutant

Ranchi's NO_2 profile is the most worrying among the three cities with respect to NAAQS limits. Winter monthlies in December and January at Kantatoli Traffic Hub are close to 80 μg/m³, the 24-hour standard. It is quite paradoxical as Dhanbad and Jamshedpur have a bigger industrial emission inventory. Ranchi's vehicular traffic density is high but it occupies a small area. Moreover, it lacks any facilities for dispersion in the atmosphere (few wide boulevards, limited green buffers, high building densities in commercial cores). Also, the weather effect of cooler winter temperature of the Chota Nagpur Plateau suppresses mixing height and concentrates NO_2. Both Dhanbad and Jamshedpur witness increasing NO_2 concentrations in line with the growth of the vehicular fleet. However, compared to central monitoring stations (JSPCB, 2022; CPCB National Air Quality Monitoring Programme (NAMP), 2023) at Kantatoli Ranchi, the values have not yet reached that level. This observation has serious policy implications:

traffic management of commercial corridor intersection in Ranchi deserves immediate priority intervention even before industrial controls are taken up.

Seasonal Variation Comparative Analysis

The three cities exhibit the canonical Indian monsoon seasonality: elevated pollution concentrations during winter (November–February) due to thermal inversions, reduced atmospheric mixing, and domestic heating combustion; rapid decline during June–July, when wet scavenging starts with monsoon rainfall; monsoon minima during July–August; and post-monsoon transition surge during September–October, when atmosphere dries and burning starts again. Yet, the seasonal variation extent differs systematically with city and pollutant. Dhanbad has the smallest seasonal PM_{10} amplitude because of its continuous coal mining throughout the year which leads to a near-constant baseline for coarse dust emissions. As such, neither the monsoon rains nor the winter inversions alter the condition very much. The $PM_{2.5}$ seasonal variation in Ranchi is stronger than of PM_{10}. This is consistent with emissions from combustion sources. Although such emissions are available throughout the year, they respond more strongly to meteorological trapping than by crustal dust. The industrial sectors of Jamshedpur, so2, and metallic pm show varying degrees of seasonality. Due to their production schedule, steel companies show more effects of variability which are more prominent than Ranchi mostly dominated by vehicular capacity emissions. (Srivastava & Jain, 2020)

Integrated Source Attribution

Ranchi Site Pollution Hierarchy

Combining all four pollutants across both measurement years generates and a site hierarchy for Ranchi that was statistically robust (Table 9). Kantatoli (Site 2) is the most polluted site for all four pollutants. It is dominated by traffic emissions: peak NO_2, highest $PM_{2.5}/PM_{10}$ ratio (> 0.93), and typical rush-hour concentration peaks unequivocally point to mobile sources as the main driver. Tupudana (Site 1) is second on the list where high SO_2 and peak $PM_{2.5}$ evidently fossil fuel combustion. Industrial processes metal foundries, smelters and thermal generators are typical to the Tupudana corridor. The SO_2 concentrations recorded during the study period were found to be below NAAQ standards. For instance, at Site 1, which is in proximity to industrial land, the SD was of little relevance.

Inter-City Source Differentiation

The trio of cities offers an excellent natural experiment on the type of industrial emissions. Ranchi exemplifies a model dominated by traffic and urbanization, which results in the patterns of pollution it exhibits. The higher than normal organic carbon content and elemental carbon content suggests diesel and petrol combustion while the higher ratio of NO_2 to NO_2 plus SO_2 indicates mobile source dominance. The formation of secondary inorganic aerosol (that is, nitrates and ammonium sulphates) by precursors of traffic emissions is also a result of the winter formation chemistry that takes place there. Dhanbad is the epitome of the coal extraction model as indicated by the elevated PM_{10} concentrations with a very high crustal fraction (Al, Si, Ca, Fe derived from coal overburden), an anomalously high ratio of SO_2 to NO_2 (which shows that it is not from vehicle emission, but due to the burning of sulphur-rich coal) and the unique signature of coal seam fire emissions (with combustive products at anomalously high temperatures including PAHs, CO, carbonaceous particulates). Jamshedpur serves as the metallurgical industry's prototype. The $PM_{2.5}$ is rich in iron, manganese, chromium and nickel due to steel manufacturing activities, elevated SO_2 resulting from sintering process, and PAH contamination from the coke oven. The targeted emission reduction strategies depend on these source signatures. If a PM filter mandate is effective in reducing PM due to vehicular source in Ranchi, it will have negligible impact on coal dust problem in Dhanbad. Controls that successfully regulate industrial stack emissions at Jamshedpur's point sources will not work at Ranchi. NCAP's city-specific action plans have to consider such source divergences rather than applying uniformly the generic nationwide emission reduction approach.

Public Health Risk Assessment

$PM_{2.5}$ Exposure and Mortality Burden

In Ranchi, all five locations surpassed the 40 $\mu g/m^3$ $PM_{2.5}$ NAAQS by 56% to 179%. Therefore, the Government of India continues to fail to protect human health as no resident in Ranchi is breathing compliant air. As per WHO's

guideline of 5 μg/m³, every person in Ranchi is exposed to level whose average is over 12 times the limit. The WHO's dose-response function shows that any cause mortality can increase by 6-7% with an increase of $PM_{2.5}$ by 10μg/m³. Overall, citizens of Kantatoli and Tupudana area are witnessing a high attributable mortality of $PM_{2.5}$alone. In Dhanbad, the combination of high levels of $PM_{2.5}$and SO_2 poses a breathing risk. Miners and peri-mine communities will be affected seriously. Epidemiological studies of Indian coal mine workers have indicated pneumoconiosis prevalence rates of 8–15% among populations with prolonged exposure (Patra et al., 2016).

NO_2 and Respiratory Disease

The study site in Kantatoli has reported concentrations of NO_2 annually averaging around 45–50 μg/m³. NO_2 exposure at such concentrations has been linked to incidence of asthma, impaired growth of lung function in children and increased vulnerability to infections (WHO 2021; Landrigan et al. 2018). Because their lungs are still growing, children are at a greater risk. In addition, they spend more time outdoors than older individuals during the day, when NO_2 and $PM_{2.5}$ concentration levels from traffic are higher. Kantatoli is a major commercial transit hub bringing daily footfall from across Ranchi, although the populations exposed are not just those of the resident catchment of the monitoring station, estimates therefore indicate any working day 150,000–200,000 people are exposed to these concentrations.

Winter Cumulative Risk Period

The months between November and January posed the maximum cumulative health risk in all three cities when the peak concentrations of SO_2, NO_2 and PM occur coincidentally. The atmospheric conditions at this time (low wind speeds (5-7 km/h at Ranchi), temperature inversions, reduced mixing heights) are also ideal for maximisation of personal exposure duration and intensity. The fact that there's no real-time public air quality index system available in all three cities means there's no system to allow residents to alter behavior during these hazardous times. Jharkhand cities do not have any school closure levels, any public advisories nor any emergency measures are active as in GRAP system in place in Delhi.

Children and Elderly Vulnerability

Children below five years and adults above 65 years are the most physiologically vulnerable groups in the population. When children are exposed to $PM_{2.5}$ levels of 35 μg/m³ or higher during critical developmental windows, they have impaired lung function that persists into adulthood (Landrigan et al. 2018). All five monitoring sites in Ranchi and the secondary data profiles for Dhanbad and Jamshedpur show annual mean $PM_{2.5}$ levels well above 60 μg/m³. Therefore, the entire child population of the Jharkhand urban cluster is chronically exposed above this level. Exposure to PM and NO_2 at observed concentrations substantially raises risk of cardiovascular incidences among the elderly, especially during the inflammatory response peak months of winter (Balakrishnan et al., 2019).

Policy Implications and Recommendations

Ranchi — Priority: Traffic Emission Control

Since vehicular emission contributes the most to Ranchi's $PM_{2.5}$ and NO_2 burden, traffic management and fleet transition should be priority intervention points. Actions that are recommended contain.Speed up transitioning to CNG and electric vehicles for public transit along the Kantatoli commercial corridor. Aim for a 30% diesel fleet reduction within 3 years. During winter season (November-January) when NO_2 near NAAQS limit, implement odd-even vehicular restriction schemes or congestion pricing at Kantatoli during morning and evening peak hours. Implement remote-sensing pollution under control or PUC enforcement systems at major road entry points because consistent field studies show that vehicular emissions from Indian cities on average originate from 5-10% worst mechanical condition vehicles that account for 20-30% of total emissions. Set up specific cycling paths and pedestrian first priority streets to link up major residential areas with Kantatoli to ensure short-trip mode share from motorized vehicles to increase. Make installations of charging points for electric vehicles (EVs) mandatory for all commercial construction permit applications in the Kantatoli zone to accelerate private EV adoption.

Dhanbad — Priority: Coal Dust and Mine Fire Suppression

Dhanbad's air quality challenge is structurally different and require coal sector specific solutions. Within five kilometers of residential areas, all currently running open cast collieries would be required to mandatorily install systems for suppression of fugitive dust (such as water sprinklers, enclosed conveyor belt, vegetative barriers, etc).The Mine Fire Control Programme of BCCL for Jharia coalfield should be sped up by action on seams which emit fire on surface in the residential areas. Require all coal washeries and all coal handling facilities having more than 1 million tonnes annual throughput to continuously monitor and publicly report emissions. Create and implement monitoring networks for $PM_{2.5}$ and SO_2 at the village level in mine- adjacent communities. These communities are presently under-represented in the CPCB NAMP monitoring networks. The objective of this step is to assess exposure gradients near to the point sources.

Jamshedpur — Priority: Industrial PM and Metallic Aerosol Control

Jamshedpur has a comparatively well-developed industrial environmental management system on which to build. Ensure implementation of CEMS for all major stacks at Tata Steel Jamshedpur followed by real-time transmission of data to JSPCB and accessible to the public. Programs for baghouse and ESP upgrades of sinter plants, which have been historically the highest PM emission process unit in integrated steel plants, should be given highest priority for implementation. A 40 per cent reduction in sinter PM emissions is possible in five years. The health alert protocols should be activated when ambient concentrations of aerosol iron, manganese and chromium reach threshold concentrations. Ambient monitoring of metals should also be undertaken at residential stations located along the edge of the plant boundary. The vehicular NO_2 burden in Jamshedpur's expanding commercial zones is continuously worsening. Before NO_2 levels reach that of Ranchi's Kantatoli, Jamshedpur should be incentivized to transition to EVs. There should also be enforcement of Bharat Stage-VI.

Cross-City Governance Recommendations

Set up a Jharkhand state air quality monitoring network (JSAQMN) by deploying real-time sensor nodes in all these three cities with standard QA/QC protocols and dashboard for easy public access. We must urgently implement air quality index (JAQI) along the lines of GRAP in the National capital but customizable to Jharkhand. Health advisory alerts in case of moderate to poor require monitoring. Monitoring if the health advisory of the JAAQI is active and whether it is going off in case of any moderate to poor air quality episodes. As part of the approval process for all industrial, major infrastructure and new township developments in all three cities, make air quality impact assessments mandatory. Include tree cover expansion targets in city master plans: a 20% increase in tree cover of Kantatoli and equivalent high-density zones within five years using native high-PM-interception species (Ficus benghalensis, Terminalia arjuna, Mangifera indica). Engage a joint Jharkhand health impact assessment that will quantify the attributable disease burden from $PM_{2.5}$ and NO_2 exposure in all three cities to provide the economic case for policy investment.

CONCLUSIONS

The study provides the first multi-city air quality assessment of the three major cities or urban centres of Jharkhand, namely, Ranchi, Dhanbad and Jamshedpur, using systematic and comprehensive primary field data collected for Ranchi, secondary published data for the comparative cities and a scientific rationale and connecting pollution profiles to the source sector characteristics of the respective cities. The findings are clear on all fronts. In Ranchi, all five land-use zone monitoring sites showed PM_{10} concentrations exceeding NAAQS in both years of measurement, with annual means of 97–110 $\mu g/m^3$ against a standard of 60 $\mu g/m^3$. Kantatoli recorded a $PM_{2.5}$ exceedance of 111.44 $\mu g/m^3$, which is 279% of NAAQS and 2,229% of the WHO guideline. The monitored air quality mostly reflected vehicular exhaust, and not heavy industry. At Kantatoli, under the business as usual scenario, the NO_2 24 hour average monthly values during winter are close to the limit set by NAAQS. The annual rate of increase is 5.9% which is likely to exceed the limit set by NAAQS within the next 3-5 years. SO_2 is presently compliant at all Ranchi locations, but is showing annual rising trends of 5–11% at the industrial and traffic sites. The most crucial takeaway is

that 2023 air quality turned worse than 2022 despite higher monsoon rainfall in 2023 – thus definitively proving that emission growth is the controlling driver, not interannual meteorological variability.

On comparison with Dhanbad, the quality of air of the two steel townships shows that there is much higher contribution of coal mining operations in Dhanbad as seen from the coarser particles that show up at Dhanbad. SO_2 appears to be the signature differentiating pollutant for Dhanbad. Coal seam fires represent an essentially uncontrolled emission source at Dhanbad that is unique to the Indian urban scene. The heavy metal aerosols present in the air of Jamshedpur come from the steel processing area. The NO_2 profile which is traffic dominated of Ranchi represents the most critical compliance failure of the three cities and surprisingly has a higher level of this pollutant than more industrial cities around. The ratio of $PM_{2.5}$ to PM_{10} in various cities reveals the nature of their air pollutants. This ratio was highest in Ranchi where traffic was heavy (greater than 0.90); and intermediate in certain industrial sites of Jamshedpur (0.60-0.75). Further, the ratio was lowest in Dhanbad with stations close to mining sites (0.50-0.65).This $PM_{2.5}$ / PM_{10} ratio across cities is expected to fingerprint the dominant source sector and hence guide the identification of targeted emission control strategies. The study confirms the effects of intact urban forest cover, that is, a 49 $\mu g/m^3$ reduction in annual mean $PM_{2.5}$ and 3-4°C reduction in summer temperatures in Ranchi. The monitoring site at Kantatoli in Ranchi is most urbanized and hence severely polluted with an annual mean $PM_{2.5}$ of 111.44 $\mu g/m^3$. The least polluted site is Birsa Zoological Park with $PM_{2.5}$ of 62.48 $\mu g/m^3$. The strongest locally grounded empirical evidence available for investing in urban forest expansion as an air quality and climate adaptation strategy. The cities of Jharkhand have the chance to fix their air quality before it get as bad as the most polluted megacities of India. This data is the basis for that action and the reason.

ACKNOWLEDGEMENTS

The authors are thankful to the Department of Environmental Science, Dr. Shyama Prasad Mukherjee University, Ranchi, for providing laboratory facilities and infrastructure. The authors also acknowledge CPCB and JSPCB for maintaining publicly accessible air quality monitoring datasets that enabled the comparative analysis.

Funding: No external funding was received.

Author Contributions: S. Prasad: conceptualization, field data collection, statistical analysis, original draft. N. Lal: supervision, validation, review and editing.

Competing Interests: The authors declare no competing interests.

Data Availability: Primary Ranchi dataset available from the corresponding author upon reasonable request. Secondary data sources are publicly available from CPCB and JSPCB.

ABSTRACT

Diaspora literature plays a crucial role in understanding the complexities of identity and belonging in a globalized world. The Golden Son by Shilpi Somaya Gowda is a significant contribution to Indo-Canadian literature that explores the emotional and cultural struggles of migration. This research paper examines how the novel represents diaspora identity and the search for belonging through its central characters, particularly Anil and Leena. The narrative follows Anil, a young man who migrates from rural India to the United States in pursuit of professional success, while remaining deeply tied to his cultural roots. His journey reflects the tensions between tradition and modernity, as well as the psychological challenges of adapting to a new cultural environment. The novel portrays the experience of living "between two worlds," highlighting issues such as cultural conflict, alienation, and identity crisis. This study adopts a thematic and analytical approach to examine how Gowda constructs diaspora identity as fluid and evolving. It also explores the role of family expectations, social norms, and personal ambition in shaping an individual's sense of belonging. The paper argues that the novel presents belonging not as a fixed state but as a continuous process of negotiation between past and present, homeland and host land. By analyzing the novel, this research contributes to a deeper understanding of Indo-Canadian diaspora literature and its engagement with identity, migration, and cultural hybridity in the modern world.

Keywords: Diaspora, represents, identity, migration, and cultural hybridity

INTRODUCTION

In the contemporary globalized world, migration has become a defining feature of human experience, giving rise to what is commonly referred to as diaspora communities. The term "diaspora" denotes the dispersion of people from their original homeland to different geographical locations, often resulting in complex cultural, emotional, and psychological experiences. Literature emerging from such communities, particularly Indo-Canadian literature, provides deep insight into the struggles of identity and belonging faced by immigrants. Among the notable works in this field is The Golden Son by Shilpi Somaya Gowda, which vividly portrays the challenges of navigating between cultures. The novel centers on the life of Anil Patel, a young man from a rural Indian village who migrates to the United States to pursue a career in medicine. As the first member of his family to leave his homeland, Anil carries the weight of familial expectations and cultural values. His journey reflects the quintessential diasporic experience, characterized by the tension between maintaining one's cultural identity and adapting to a new social environment. The narrative also juxtaposes Anil's story with that of Leena, his childhood friend, who remains in India and faces her own struggles within traditional societal structures. One of the central themes of the novel is the concept of diaspora identity. Diasporic identity is inherently complex and fluid, shaped by the interaction between the culture of the homeland and that of the host country. Anil's experiences in the United States illustrate this duality. On one hand, he embraces opportunities for professional growth and personal freedom; on the other hand, he grapples with feelings of alienation and cultural displacement. He is neither fully at home in America nor entirely connected to his roots in India, embodying what scholars describe as a "hyphenated identity."

The novel also explores the idea of belonging, which is closely linked to identity. Belonging refers to the sense of acceptance and inclusion within a particular community or cultural context. For diasporic individuals like Anil, belonging is not easily attainable. His interactions in the United States reveal the subtle and overt challenges faced by immigrants, including cultural misunderstandings and social exclusion. At the same time, his periodic returns to India highlight a growing sense of distance from his own culture, further complicating his sense of belonging. Furthermore, the novel emphasizes the role of cultural conflict in shaping diaspora identity. Anil's internal struggle is marked by the clash between traditional Indian values and the modern, individualistic ethos of Western society. This conflict is evident in various aspects of his life, including his relationships, career choices, and personal beliefs. The narrative demonstrates how these conflicting forces create a sense of instability and uncertainty, which is a defining feature of diasporic existence. Another important dimension of the novel is its exploration of cultural hybridity. Cultural hybridity refers to the blending of different cultural influences, resulting in new forms of identity. Anil's character exemplifies this hybridity, as he gradually integrates elements of both Indian and American cultures into his identity. This process is neither linear nor straightforward; rather, it involves continuous negotiation and adaptation. The novel suggests that such hybridity is not a sign of loss but a creative and dynamic response to the challenges of migration. In addition to individual identity, the novel also addresses broader social and cultural issues, such as class differences, gender roles, and family expectations. Through the character of Leena, Gowda highlights the constraints faced by women in traditional Indian society, thereby providing a contrast to Anil's experiences abroad. This dual narrative structure enriches the exploration of identity and belonging, offering multiple perspectives on the diasporic condition.

The significance of this study lies in its focus on how The Golden Son contributes to the discourse on diaspora identity and belonging. By analyzing the novel, this research aims to uncover the ways in which literature reflects and shapes our understanding of migration and cultural interaction. The novel not only portrays the struggles of diasporic individuals but also celebrates their resilience and adaptability. The Golden Son serves as a powerful exploration of diaspora identity and the search for belonging. Through its nuanced portrayal of characters and their experiences, the novel captures the complexities of living between cultures and highlights the ongoing process of identity formation in a globalized world.

LITERATURE REVIEW

The study of diaspora literature has become one of the most significant areas in contemporary literary criticism because it addresses questions of migration, identity, displacement, and belonging. Scholars have increasingly examined how diasporic narratives reflect the emotional and psychological consequences of living between cultures. In the context of Indian English fiction, diaspora writing often focuses on the negotiation between homeland values and host-country realities. The Golden Son by Shilpi Somaya Gowda contributes meaningfully to this literary tradition by portraying migration not merely as physical movement but as a deeply transformative psychological and cultural experience. A major theoretical foundation for diaspora studies comes from Stuart Hall, who argues that identity is not fixed but continuously formed through history, culture, and representation. Hall's understanding of cultural identity is highly relevant to The Golden Son, where Anil's sense of self changes through his movement from rural India to America. His identity is not stable; instead, it evolves as he encounters new cultural expectations, social relationships, and professional responsibilities. Hall suggests that diasporic identity exists through "becoming" rather than simply "being," and this concept is visible throughout Anil's experiences.

Similarly, Homi K. Bhabha introduces the idea of hybridity, which is central to understanding diasporic identity in the novel. Bhabha explains that when cultures interact, a "third space" emerges where new identities are formed. Anil occupies such a third space because he cannot fully belong either to traditional Indian village culture or to American urban life. His professional success in America does not eliminate his attachment to Indian family values. Instead, his life becomes a continuous negotiation between these cultural systems. Bhabha's theory helps explain why Anil's identity remains layered and unstable rather than resolved. The concept of "imagined belonging," often discussed in diaspora studies, also applies to the novel. Scholars note that migrants frequently idealize both homeland and hostland, yet remain emotionally unsettled in both spaces. Anil initially imagines America as a place of freedom and professional achievement. However, after arrival, he experiences loneliness, unfamiliarity, and subtle exclusion. His medical residency introduces him to competition and emotional distance that contrast sharply with village intimacy. This reflects what diaspora critics identify as the emotional contradiction of migration: opportunity often coexists with displacement.

Several scholars studying Indian diasporic fiction have emphasized that migration narratives often focus on male mobility while female characters remain tied to local structures. In The Golden Son, this pattern is challenged through the equally important narrative of Leena. While Anil moves geographically, Leena's struggle occurs within the confined social structures of rural India. Her marriage, domestic suffering, and limited freedom expose how gender shapes access to mobility. Critics of contemporary Indian fiction often argue that women's immobility can reveal social realities as powerfully as migration itself. Leena's character therefore broadens the novel's diasporic framework by showing that belonging is also contested within the homeland. Another important scholarly perspective comes from research on transnational family structures. Migration does not sever family obligations; instead, it often intensifies them. Anil's success abroad remains linked to expectations from his father, brother, and village community. Literary critics of transnational fiction argue that migrants often carry invisible emotional burdens because family identity continues across borders. This is evident when Anil must repeatedly evaluate whether personal ambition should outweigh responsibility toward home. The novel also aligns with studies of professional diaspora, particularly medical migration. Research on immigrant doctors often notes that professional success abroad does not automatically produce emotional security. In Anil's case, hospital life in America represents discipline, hierarchy, and distance. His role as a doctor creates social status but also isolation. The contrast between healing others and struggling internally gives the novel additional depth.

Comparatively, The Golden Son shares thematic concerns with The Namesake and Interpreter of Maladies, where diasporic identity is similarly shaped by cultural negotiation and emotional fragmentation. However, Gowda's novel differs because it maintains equal narrative attention on village India, thereby refusing to separate migration from homeland realities. Thus, existing scholarship on diaspora, hybridity, gender, and transnational identity provides a

strong framework for reading The Golden Son. The novel contributes uniquely by showing that belonging is not achieved through migration alone but remains a complex emotional process shaped by culture, memory, and moral responsibility.

Analysis of Diaspora Identity, Cultural Conflict, and Hybridity in the novel:

Cultural Conflict and Identity Crisis

The Golden Son presents cultural conflict as one of the most central dimensions of diasporic existence. The novel demonstrates that migration is not only geographical movement but also psychological displacement. Through Anil Patel's journey from rural Gujarat to America, the narrative explores how individuals encounter conflicting cultural systems that challenge previously stable forms of identity. Before migration, Anil's life is shaped by family hierarchy, collective values, village familiarity, and clearly defined social roles. His identity is rooted in community recognition and family expectation. However, upon entering American society, these foundations become unstable because the new environment demands self-definition in unfamiliar terms. In rural India, Anil's achievements belong not only to himself but to his family and village. His educational success symbolizes collective aspiration. The title itself reflects this burden: the "golden son" is expected to fulfill family pride and social mobility. Yet America introduces a contrasting value system centered on individuality, personal choice, and emotional independence. This cultural difference creates internal conflict because Anil cannot easily detach himself from inherited expectations. His experience in hospital life intensifies this crisis.

In India, medicine represented service and social honor; in America, it also becomes institutional competition, technical discipline, and emotional detachment. He must learn not only medical systems but also social codes, communication styles, and professional behavior that differ from his upbringing. The struggle is subtle yet constant: language, humor, interpersonal distance, and decision-making all require adaptation. This conflict produces identity uncertainty. Anil gradually realizes that success abroad does not automatically create belonging. Though he gains professional opportunity, he also experiences emotional isolation. His loneliness in America reflects a common diasporic condition where migrants appear socially integrated but remain internally unsettled. He belongs neither fully to the host society nor completely to the homeland he left behind. The novel shows that identity crisis often emerges through ordinary moments rather than dramatic events. Anil's meals, conversations, clothing choices, and social relationships all become sites of negotiation. Even his silence often indicates uncertainty about how much of himself can be expressed within a new cultural setting. This demonstrates that diaspora identity is lived daily through repeated acts of adjustment. Importantly, cultural conflict is not presented as simple opposition between East and West. Gowda avoids binary stereotypes by showing complexity in both spaces. Rural India contains affection but also social rigidity; America offers opportunity but also alienation. Therefore, Anil's conflict is not about choosing one culture over another but about learning how to survive within both.

Hybridity and the Formation of a New Self

The concept of cultural hybridity is central to understanding Anil's transformation. Rather than abandoning one culture for another, he gradually develops a layered identity shaped by both Indian and American influences. Hybridity in the novel is not immediate; it develops slowly through discomfort, adaptation, and self-reflection.At the beginning of his migration, Anil attempts to preserve familiar values while functioning within foreign surroundings. He remains emotionally connected to family, village memory, and cultural discipline. Yet over time, his behavior changes. He becomes more professionally assertive, more individually reflective, and increasingly aware of personal choice. These changes do not erase his Indian identity; instead, they create a mixed cultural consciousness. His interactions with colleagues in America reveal this process. He learns how to participate in professional dialogue, interpret social independence, and understand emotional boundaries different from those in India. However, he often evaluates these experiences through inherited moral values. Thus, every new experience passes through both cultures simultaneously. Hybridity also appears in his emotional responses. He admires American efficiency and opportunity, yet he misses the intimacy of collective life. He values professional advancement but questions whether ambition alone creates fulfillment. This dual awareness reflects a hybrid identity in which both cultural systems remain active. The novel suggests that hybridity is creative but difficult. It offers expanded perspective but also

emotional instability. Migrants like Anil gain the ability to move between worlds, yet this mobility often produces uncertainty because no single cultural framework feels complete. Importantly, Gowda presents hybridity as dynamic rather than finished. Anil does not arrive at a final identity. Instead, he continues negotiating language, loyalty, ambition, and memory. His identity remains in process, which reflects modern diasporic experience accurately. This fluidity also affects his relationships. He begins to understand that emotional choices cannot be determined solely by family tradition or solely by Western independence. Both influence his decisions. Therefore, hybridity becomes not merely cultural blending but an ethical framework through which he interprets life.

Family Expectations and Diasporic Responsibility

Family remains one of the strongest forces shaping Anil's diasporic experience. Migration in the novel is never purely individual because Anil's departure carries collective meaning. His family invests emotional hope, social prestige, and future expectation in his success. His father's pride reflects traditional Indian family structures where the son's advancement symbolizes family progress. Education becomes a means of social mobility, and foreign success becomes proof of achievement. However, such pride also creates pressure. Anil cannot fail privately because his success belongs publicly to others. This creates what may be called diasporic responsibility. Even while physically distant, he remains emotionally accountable to family decisions, village needs, and moral obligations. Letters, memories, and expectations constantly connect him to home. Migration therefore expands responsibility rather than reducing it. The contrast between personal ambition and family duty becomes especially significant when Anil begins to evaluate his future. America offers stability and professional success, yet family ties continue to demand attention. The question becomes whether belonging is defined by where one succeeds or where one remains responsible. The novel shows that many migrants experience guilt alongside success. Professional advancement abroad often produces emotional distance from family realities at home. Anil's growing awareness of Leena's suffering intensifies this moral tension because he recognizes that his own mobility contrasts sharply with others' limitations. Family expectation also shapes emotional restraint. Anil cannot freely redefine himself because inherited values continue to regulate his decisions. Even in a new country, internalized family discipline remains powerful. Gowda therefore portrays migration as morally complex. Success abroad is not liberation from obligation; rather, it introduces new forms of ethical conflict.

Leena and Gendered Belonging

Leena's narrative is essential because it reveals that belonging is also shaped by gender. While Anil moves internationally, Leena remains within village structures where freedom is severely restricted. Her life exposes how women often experience immobility even within their own homeland. Leena's marriage demonstrates how traditional social systems regulate female identity. Her role is defined by domestic obedience, endurance, and silence. Unlike Anil, she has limited access to education, mobility, and self-determination. This contrast reveals unequal distribution of opportunity within the same cultural context. Her suffering is not only personal but structural. The expectations placed upon her reflect broader patriarchal systems in which women are valued primarily through family roles. Even when emotionally strong, her choices remain socially constrained. This creates another form of diaspora-like displacement: Leena experiences alienation within home itself. She belongs physically to the village yet lacks full emotional belonging because her individuality is suppressed. Thus, the novel suggests that displacement can occur without migration. Leena's presence also challenges male-centered migration narratives. If Anil represents outward mobility, Leena represents inward endurance. Together they reveal two forms of struggle shaped by social hierarchy. Her emotional resilience becomes one of the novel's strongest ethical elements. Gowda does not portray her merely as victimized; rather, she becomes morally central because her suffering exposes the limitations of traditional structures. Through Leena, the novel argues that belonging must include dignity and agency. Without these, physical presence in homeland does not create true belonging.

Memory, Return, and Emotional Homeland

An important aspect of diasporic identity in the novel is memory. For migrants, homeland often survives emotionally through remembered details rather than continuous presence. For Anil, village life remains active through memory even while he adapts abroad. Food, language, family voices, and childhood associations continue to shape his

internal world. These memories prevent complete assimilation because emotional belonging remains tied to earlier life experiences. However, return complicates memory. When Anil reconnects with India, he realizes that both he and home have changed. Homeland is no longer exactly as remembered. This creates a common diasporic realization: memory preserves a version of home that reality cannot fully restore. Thus, belonging becomes emotionally unstable. America offers present opportunity; India offers remembered attachment. Neither alone provides complete resolution. The novel suggests that home may ultimately become relational rather than geographical. Belonging exists where ethical responsibility, emotional truth, and human connection are sustained. This insight gives the novel its broader significance within diaspora literature: migration does not erase origin, and return does not fully restore identity. Instead, identity remains suspended between movement and memory.

Findings of the Study

The analysis of The Golden Son reveals that diaspora identity is presented as a dynamic and continuously negotiated process rather than a stable cultural condition. The novel demonstrates that migration does not simply involve geographical relocation; instead, it initiates profound psychological, emotional, and social transformations that affect how individuals understand themselves and their place in the world. Through the experiences of Anil Patel, the study finds that diasporic identity emerges through continuous interaction between inherited cultural values and newly encountered social realities. One of the most significant findings of this study is that cultural conflict remains central to diasporic identity formation. Anil's migration from rural India to the United States places him in an environment where traditional values are constantly challenged by modern Western practices. His professional life in America offers independence, opportunity, and social mobility, yet these advantages do not remove his attachment to family obligations and emotional memory. The study shows that this duality creates an internal conflict in which identity becomes divided between competing systems of belonging. Anil's life illustrates that migrants often exist in a condition of partial belonging, where neither homeland nor hostland fully satisfies emotional and cultural needs. A second important finding concerns the role of hybridity in identity construction.

The novel demonstrates that diasporic identity is not based on choosing one culture over another but on gradually integrating elements from both. Anil does not abandon his Indian identity after migration; rather, he adapts selectively while preserving emotional ties to his origins. His professional discipline, communication style, and social understanding evolve in America, but his moral judgments continue to reflect family values learned in India. This finding supports the argument that hybridity is not cultural loss but cultural transformation. The novel presents hybridity as a realistic response to migration, where individuals create new identities without completely dissolving earlier affiliations. The study also finds that family expectation remains one of the strongest forces shaping diasporic consciousness. Although Anil physically moves away from India, his family continues to influence his decisions through emotional responsibility and moral obligation. His educational success is treated not as private achievement but as collective family honor. This indicates that in many diasporic contexts, migration intensifies family responsibility rather than reducing it. The emotional burden of representing family ambition abroad becomes a defining feature of Anil's identity. Thus, the novel presents diaspora not as personal freedom alone but as responsibility carried across borders.

Another major finding concerns the contrast between mobility and immobility through the parallel narrative of Leena. While Anil experiences global movement, Leena remains within restrictive village structures shaped by gender inequality and patriarchal expectations. The study finds that her narrative broadens the meaning of displacement. Although she does not migrate internationally, she experiences emotional alienation within her own social environment. Her lack of autonomy in marriage and domestic life demonstrates that belonging cannot be understood simply through physical location. The novel therefore suggests that social exclusion within homeland may produce a condition similar to displacement. Gender emerges as a crucial factor in determining access to belonging. The study finds that male mobility and female restriction operate as parallel realities within the novel. Anil receives education, travel, and professional advancement, whereas Leena's possibilities are shaped by traditional domestic expectations. This contrast exposes unequal structures within society and highlights how belonging is differently experienced by men and women. Through Leena's suffering, the novel critiques social

systems that allow male advancement while limiting female agency. The study further reveals that memory functions as an important element in diasporic Identity. Even while adapting to American life, Anil remains emotionally connected to India through remembered experiences, family relationships, and village associations. However, the study finds that memory does not provide complete comfort because return to homeland also reveals change. The India he remembers is not identical to the India he later encounters. This creates emotional complexity in which homeland exists partly as memory and partly as transformed reality. Finally, the study finds that belonging in the novel is presented not as a final achievement but as an ongoing process of negotiation. Neither America nor India offers complete resolution for Anil. Instead, belonging develops through ethical responsibility, emotional connection, and self-awareness across multiple cultural spaces. The novel ultimately suggests that modern diasporic identity is fluid, relational, and unfinished.

CONCLUSION

The study of The Golden Son demonstrates that diaspora identity is a complex and evolving condition shaped by migration, cultural interaction, memory, and social responsibility. Through the parallel narratives of Anil and Leena, the novel offers a nuanced understanding of how belonging is negotiated within both global and local contexts. Rather than presenting migration as a simple movement toward success, the novel reveals the emotional and cultural tensions that accompany the experience of living between different worlds. Anil's journey from rural India to the United States represents the central diasporic struggle between opportunity and attachment. His movement across national boundaries provides access to education, professional recognition, and personal independence, yet it also generates emotional uncertainty and cultural conflict. The study has shown that his experiences reflect the broader condition of diasporic individuals who must continuously balance inherited traditions with new social realities. His identity does not become fully American, nor does it remain unchanged by migration. Instead, it develops through ongoing negotiation between multiple cultural influences.

A major conclusion of this study is that cultural hybridity in the novel functions as a realistic and necessary response to migration. Anil gradually incorporates aspects of both Indian and American life into his sense of self, creating an identity that is neither fixed and singular. This hybridity does not suggest loss of cultural roots; rather, it reveals the ability of individuals to adapt creatively while maintaining emotional continuity with their origins. The novel therefore presents hybridity as a dynamic process of identity formation in contemporary diasporic existence.The analysis also confirms that family remains central to diasporic belonging. Even after migration, Anil's choices remain deeply influenced by family expectations, moral obligation, and emotional memory. His success abroad cannot be separated from the collective hopes of his family and village. This indicates that diaspora often extends family structures across borders rather than weakening them. The emotional responsibility carried by migrants becomes one of the defining features of their identity.

Leena's narrative significantly strengthens the novel's exploration of belonging by showing that displacement is not limited to migration. Her struggles within traditional village structures reveal how gender inequality can produce forms of alienation even within one's homeland. Through her character, the novel critiques patriarchal systems that limit female autonomy and demonstrates that belonging must include dignity, agency, and emotional recognition. The study further concludes that belonging in The Golden Son is not presented as a final destination. Neither homeland nor hostland fully resolves the characters' internal conflicts. Instead, belonging emerges as a continuous process shaped by relationships, ethical choices, and emotional understanding. Memory, return, and social responsibility remain active forces in this process. The novel contributes significantly to contemporary diaspora literature by portraying identity as fluid, layered, and unfinished. The novel successfully captures the realities of modern migration while also highlighting the enduring importance of cultural roots, human connection, and moral responsibility in shaping the search for belonging.

ABSTRACT

Maintaining optimal oral hygiene is essential as the oral cavity serves as the primary portal to the respiratory and gastrointestinal systems. Standard chemical mouthwashes like chlorhexidine cause side effects including tooth staining and mucosal irritation, driving the clinical need for safe, chemical-free herbal alternatives. This study aimed to systematically execute the pharmaceutical development of an herbal mouthwash combining four classical Ayurveda plants recognized for oral cleansing: *Bakula* (*Mimusops elengi*), *Twaka* (*Cinnamomum zeylanicum*), *Musta* (*Cyperus rotundus*) and *Haritaki* (*Terminalia chebula*), while evaluating three processing methodologies. Authenticated botanicals were processed into three distinct dosage forms: an aqueous decoction (*Kwatha*), a hydro-distillate (*Arka*) and a simple steam distillate. In vitro antimicrobial screening was performed using the standardized disc diffusion technique against *Streptococci*, *Staphylococcusaureus*, *Escherichiacoli*, and *Klebsiella pneumoniae*, measuring zones of inhibition (ZOI) after 24-hour incubation at 37°C. The *Arka* (hydro-distillate) formulation demonstrated superior and consistent efficacy, exhibiting a uniform zone of inhibition measuring 5.0 mm across all tested pathogens. Conversely, the steam distillate displayed minimal response (3.0 mm ZOI). The *Kwatha* formulation yielded poor sensitivity against *Streptococci* and *S. aureus* (3.0 mm ZOI) and failed to inhibit *E. coli* and *K. pneumoniae*. Hydro-distillation (*Arka*) effectively isolates and concentrates the volatile active principles of the selected plants. The resulting mouthwash represents a stable, safe and microbiologically

active alternative to synthetic oral rinses, successfully validating the integration and modernization of traditional Ayurvedic drug-delivery platforms.

Keywords: Herbal mouthwash, *Arka* (hydro-distillate), Antimicrobial efficacy, *Mimusops elengi*, *Cinnamomum zeylanicum*, Zone of inhibition (ZOI).

INTRODUCTION

Ayurveda prescribes mainly about the two different aspects of human life that are, preserving the health of healthy persons (*Swasthasya Swasthya Rakshanam*) and curing diseased conditions (*Aturasya Vikara Prashamanam*). The mouth of human comprises multifaceted system and functions including chewing of food, awareness about the taste and helps in baseline metabolism. As the function of the oral cavity is the prime one to get the proper starting of digestion, maintaining its health and hygiene is mostly requires. Negligence in regular oral care creates a predisposition for biofilm accumulation, dental caries, gingivitis, and severe periodontal diseases, collectively classified under the domain of *Mukharogas* (oral cavity disorders) in classical Ayurveda texts.[1] Traditional Ayurveda scriptures describe daily regimens (*Dinacharya*) dedicated to preserving oral hygiene, with specific emphasis on *Gandusha* (the practice of filling the oral cavity completely with liquid to its maximum capacity without moving it) and *Kawala* (the retention of a fluid within the oral cavity accompanied by active gargling movements).[2] These procedures traditionally employ customized herbal decoctions, oils, or aqueous extracts designed to strengthen the periodontal ligament, eliminate debris, reduce halitosis, and exert direct antimicrobial action against oral pathogens. Contemporary pharmacological research verifies these practices, suggesting that plant-derived compounds—particularly those abundant in tannins, flavonoids, and essential oils—effectively disrupt microbial cellular integrity to prevent the formation of dental plaque.[3]

In modern dental therapy, the mechanical removal of plaquevia brushing is frequently augmented by therapeutic mouthwashes.[4] Among the various chemical agents available, chlorhexidine gluconate (CHX) at a concentration of 0.2% remains the recognized gold standard due to its broad-spectrum bactericidal activity and high substantively. However, prolonged use of synthetic chemical agents is limited by multiple clinical complications.[5] Patients frequently exhibit noticeable extrinsic brownish staining of teeth and dental restorations, significant alterations in gustatory perception (taste distortion),accelerated supragingival calculus deposition, and localized desquamation or irritation of the oral mucosa.[6] Furthermore, growing concerns regarding the development of microbial resistance to chlorhexidine emphasize the need to identify alternative antimicrobial compounds. To address these limitations, the Ayurveda provides different stable, compatible, natural substances, which are without alcohol and other harmful chemicals. This research selected mainly four herbal drugs as the lower number of ingredients facilitates lower cost of production. This directly benefited the consumer to maintain oral health at lower cost.

The four medicinal plants were selected based on predefined scientific criteria, including (i) documented use in Ayurveda literature for oral hygiene and management of *Mukharoga*, (ii) reported antimicrobial, anti-inflammatory and astringent properties relevant to oral health (iii) complementary phytochemical profiles capable of providing multitarget therapeutic effects and (iv)availability of authenticated pharmacognostic standards. Equal proportions (1:1:1:1, w/w) were adopted as a preliminary formulation strategy to ensure equal contribution of each ingredient and to eliminate formulation bias while comparing different pharmaceutical processing methods. Optimization of the formulation ratio was beyond the scope of the present study and permits future investigation While traditional medicine relies on the fresh preparation of *Kwatha* (decoctions), modern consumer compliance requires stable, elegant and ready-to-use liquid formulations. This study describes the systematic pharmaceutical development of an herbal mouthwash, examining three distinct preparation methods—*Kwatha* (decoction), *Arka* (hydro-distillate), and Distillate (steam distillate)—and characterising their respective in-vitro antimicrobial behaviours against common oral and opportunistic pathogens.

MATERIALS AND METHODS

Selection of Herbal drugs

The selection of the four medicinal plants was based on both Ayurveda textual evidence and contemporary scientific literature, rather than on arbitrary selection.All four drugs are described in Ayurveda literature for maintaining oral hygiene or for treating diseases of the oral cavity.Instead of selecting multiple plants with similar actions, these four herbs were chosen because they provide complementary mechanisms relevant to oral health.

- ***Bakula* (*Mimusops elengi* L.):** It is used in classical text for its*Dantya* and *Dantadardhyakara* (strengthening teeth and gums) properties.[7]It has also potent astringent (*Kashaya*) properties, which help tighten the gingiva and manage bleeding gums.[8]
- ***Twaka* (*Cinnamomum zeylanicum* Blume):** It Is commonly included in herbal tooth powders and mouth preparations along with other *katu*, *tikta*, and *kashaya* drugs for *Dantadhavana* practice.**[9]**This drug is more valuable for its rich content of volatile cinnamaldehyde, providing both excellent aroma and broad-spectrum antimicrobial properties.[10]
- ***Musta* (*Cyperus rotundus* L.):** In Ayurveda, *Musta* is used for *Mukharoga*and*Mukhashodhana* as a supportive anti-inflammatory, astringent and cleansing herb.**[11]**[12]
- ***Haritaki* (*Terminalia chebula* Retz.):** A rich source of hydrolyzable tannins, hydrolyzable phenolics and gallic acid, which provide high antioxidant and tissue-binding properties.[13].*Haritaki* is mentioned in *Mukharoga* treatment through *GomutraHaritaki*. **[14]**

Procurement and Authentication of Herbal Drugs

The raw herbal components—bark of *Mimusops elengi* (*Bakula*)&*Cinnamomum zeylanicum* (*Twaka*), rhizomes of *Cyperus rotundus* (*Musta*) and pericarp of the fruit of *Terminalia chebula* (*Haritaki*)—were procured from the institutional pharmacy storehouse of the Gujarat Ayurved University, Jamnagar (Figure 1& Table 1). The raw drugs underwent rigorous macroscopic and microscopic validation at the Pharmacognosy Laboratory of the Institute for Post Graduate Teaching & Research in Ayurveda (IPGT&RA), confirming their identity against standard monograph benchmarks. The raw ingredients were cleared of foreign matter, shade-dried under controlled conditions and mechanically pulverized into a coarse powder suitable for pharmaceutical extraction.

Pharmaceutical Processing and Formulation Development

To evaluate the impact of extraction physics on the therapeutic profile of the polyherbal mixture, three separate pharmaceutical dosage forms were developed. The four ingredients *Bakula*, *Twaka*, *Musta* and *Haritaki*were combined in equal ratios (1:1:1:1 by weight) for all preparation batches. The objective of the present work was to identify the most suitable extraction process, so the equal proportion was adopted as an initial formulation strategy for the following scientific reasons:

- To ensure that each medicinal plant contributed equally during pharmaceutical processing and antimicrobial evaluation.
- To avoid introducing formulation bias arising from unequal quantities when the primary objective was to compare the pharmaceutical preparation methods (*Kwatha*, *Arka*, and *Distillate*), rather than to optimize the herbal composition.
- Equal proportions are commonly used in preliminary polyherbal formulation development to facilitate reproducibility and simplify interpretation of pharmacological outcomes before undertaking dose-optimization studies.

Preparation of Polyherbal *Kwatha* (Decoction)

Procedure

The mixture of the ingredients was allowed to soak in water overnight to facilitate proper penetration of water into the material. *Kwatha* is prepared by boiling one part of herb with sixteen parts of water in an open vessel on mild fire till it reduces to one eighth of original quantity. [15] The hot liquid was filtered through a multi-layered muslin cloth

and allowed to cool to ambient temperature. (Table 1, Figure 2)Total 3 batches of *Kwatha* were prepared. The size of batch 1 was 400ml, size of batch 2 is 560 ml; while it is 800ml in batch 3. As *Kwatha* has very short shelf life, it was prepared in different quantities as per the need. (Table 2). The experiments was carried out in three different batches to ensure the proportion of the *Kwatha* including the same ingredients shown in table 1 and 2.

Precaution

To prepare *Kwatha*, powder taken must be coarse. If the powder is too fine, it passes through the cloth during filtration. Secondly, when the powder is too fine it settles down at the bottom of the vessel during the process leading to charring and carbonization.Earthen or chemically inactive vessels such as stainless steel must be used.The drug particularly hard in nature must be well soaked and boiling should be carried out on moderate heat.While boiling, vessel should be kept open.Constant observation and continuous stirring.For the preparation of *Kwatha*, de-ionized water or R.O. water should be used.During the preparation, aseptic conditions should be maintained.

Preparation of Polyherbal *Arka* (Hydro-distillate):

Procedure

Alltheingredientsweremadeintocoarsepowderform.Thecoarsepowderofallingredientsweretakenandmixedinspecificamount.Water was addedin double of the total volume ofmixture and keptas itis till it absorbs the water and becomes soft.Againsameamountof waterwasaddedandkeptinsunlightfor8*praharas*andinmoonlightfor8*praharas*i.e.total48hrs.Thenitwastransferredto*ArkaPatanaYantra*i.e.distillationassemblyand*Arka*wascollectedtill*GatRasatva*.Few porcelain pieces were added to check excessive bubbling during the procedure.[16] The three different batches of the *Arka* were prepared for the ensuring of the quality. The formula shown in the table 5.

Precaution

The coarsely powdered drugs should be used.*Arka* should be preserved in an air tight container and placed in a cool and dry place to check the evaporation of volatile principles.

Preparation of Polyherbal Distillate (Steam Distillate Variant):

Procedure

A specific distillation apparatus was used. All the ingredients were coarsely powdered and mixed in specific amount as per mentioned in the table 10. The mixture was soaked in sufficient amount of water for overnight. Next day, 10 times of water was added to the mixture and transferred to the distillation assembly and heating was started. Few porcelain pieces were added to the assembly flask to check excessive bubbling during the procedure. The vapor produced, was cooled through condenser. Due to this principle the resulting aqueous distillate was collected in the closed sterile container. Distillatewascollectedupto60%oftheinitialvolume for the pure product.[17] This distillate was prepared in triplicate manner shown in table 10.

Precaution

The coarsely powdered drugs should be used. Only 60% of the distillate should be collected because the remaining part may not contain any volatile principle. Distillate should be preserved in an air tight container and placed in a cool and dry place to check the evaporation of volatile principles.

Standardization of finished products

Standardization of the prepared three different formulations *Kwatha*, *Arka* and *Distillate* were evaluated for the quality control checks by the following basic parameters and procedures.

A) Organoleptic Characters: The different organoleptic characters like color, odor and taste were observed of all the three product i.e. *Kwatha*, *Arka* and Distillate.

B) Physicochemical parameters:

Determination of pH: The pH value of an aqueous liquid may be defined as the common logarithm of the reciprocal of the hydrogen ion concentration expressed in g per lt. Although this definition provides a useful practical means for the quantitative indication of the acidity or alkalinity of a solution, it is less satisfactory from a strictly theoretical

point of view. Procedure: The pH of the samples were determined by potentiometer or pH meter. Calibrate the apparatus using standard buffer solutions and then immerse the electrodes in the sample to be examined and measure the pH by putting the combined electrode into the samples of *Kwatha*, *Arka*& Distillate. [18]

Determination of Specific gravity at room temperature: The specific gravity of a liquid is the weight of a given volume of the liquid at 25ºC (unless otherwise specified) compared with the weight of an equal volume of water at the same temperature. Procedure: Previously dried and weighed specific gravity bottle was taken and firstly filled with sample and weighed. Then washed with distilled water and kept in oven for drying. Again filled with the distilled water and weighed at room temperature. [19]

$$\text{Specific Gravity} = \frac{\text{Weight of sample at Specific Temp}}{\text{Weight of water at Same Temp}}$$

Determination of Total solid content [20]: 25 ml of the sample was taken in previously dried and weighed evaporating dish and was heated on hot water bath. After complete evaporation of the liquid, it was kept in hot air oven at 110°C till constant weight of the residue obtained. The total solid content was calculated with reference to volume taken and expressed in terms of % w/v. [20]

$$\text{Total Solid Content} = \frac{\text{Weight of Residue}}{\text{Volume of sample}} \times 100\ \%\ \text{w/v}$$

In Vitro Antimicrobial Screening Protocol

To establish the comparative therapeutic potential of the developed polyherbal formulations, the antimicrobial activities of the three mouthwash variants—*Kwatha*, *Arka*, and Distillate—were systematically evaluated using the standardized Kirby-Bauer Disc Diffusion Method, chosen for its reliability in quantifying the susceptibility of microorganisms to complex herbal extracts. The assay targeted prevalent oral pathogens, including two Gram + vebacterial species (*Staphylococcus aureus*and*Streptococci)*, two Gram – ve bacterial species (*Escherichia coli* and *Klebsiella)* to determine the respective zones of inhibition for each formulation. [21]

Microbial Panel Selection

The microbial panel was selected to include representative Gram-positive and Gram-negative bacteria associated with oral and opportunistic infections. Streptococci spp. were selected because they are primary colonizers of dental plaque and important etiological agents of dental caries. *Staphylococcus aureus* was included as a clinically relevant opportunistic oral pathogen, while *Escherichia coli* and *Klebsiella pneumoniae* were selected as representative Gram-negative organisms to evaluate the broad-spectrum antibacterial activity of the formulation.[22] This preliminary study was designed to compare different pharmaceutical preparation methods rather than to evaluate activity against the complete oral microbiome These selected strains were cultured on Sheep blood agar media for 18 to 24 hours at 37 °C to ensure optimal physiological state before inoculation, after which bacterial suspensions were prepared using sterile water.[23] Turbidity was subsequently adjusted to a 0.5 McFarland standard to ensure consistent inoculum density.[24] The standardized suspensions were then evenly distributed onto Milar Hilton agar plates to facilitate the precise measurement of zones of inhibition.[25]

Culture Media Preparation and Inoculation

Müller-Hinton Agar (MHA) media was prepared, autoclaved at 121°C at 15 psi pressure for 20 minutes, and poured into sterile Petri dishes under a laminar airflow workbench to achieve a uniform depth of approximately 4.0 mm. The agar plates were allowed to solidify completely. Bacterial strains were adjusted to a standard inoculum density matching the 0.5 McFarland turbidity standard (sim 1.5 \times 10) using sterile normal saline. The optimized

bacterial suspensions were seeded uniformly across the agar surfaces using sterile cotton swabs to establish homogeneous lawns.

Disc Impregnation and Incubation

Sterile, blank filter paper discs (6.0 mm diameter, Whatman No. 1) were impregnated with exactly 80 ml of the respective undiluted polyherbal mouthwash preparations. Utilizing sterile forceps, the treated discs were positioned precisely onto the inoculated agar surfaces with uniform spacing. The plates were left undisturbed for 30 minutes at room temperature to allow complete outward radial diffusion of the extracted phytochemicals into the surrounding agar matrix. The culture plates were then incubated in an upright position within a digital incubator maintained at 37 degree for a continuous duration of 24 hours. Following incubation, the plates were inspected for clearing, and the absolute Zones of Inhibition (ZOI) were measured diagonally using digital Verniercallipers. Each assay run was performed in triplicate to ensure reproducibility.

RESULTS

Organoleptic and Physical Characteristics

The three formulation pathways produced distinctive physical properties, reflecting their differing physicochemical profiles.

Kwatha

Three batches of *Kwatha* were prepared to evaluate process reproducibility using equal proportions (1 part each) of *Bakula*, *Twaka*, *Haritaki*, and *Musta* (Table 1). Total combined drug volumes for Batches I, II, and III were 200 ml, 280 ml, and 400 ml, respectively. These were mixed with corresponding water volumes of 1600 ml, 2240 ml, and 3200 ml (Table 4).

Physical Observations

Consistent physical transformations were observed across all batches during the heating process shown in table 2 and 3. Initial Stage: The mixture began as a light brown liquid at room temperatures of 28°C to 30°C. Heating Phase: Progressive heating led to surface frothing, which intensified as temperatures rose. Maturation: As temperatures peaked between 108°C and 110°C, the liquid darkened, drug particles settled and steady evaporation occurred. Duration: The time required to reach the final evaporation stage was proportional to the batch volume, taking 90 minutes for Batches I and II, and 180 minutes for the larger Batch III. (Table 3 & Figure 2) Final Yield To achieve standard concentration, boiling was sustained until the liquid was reduced to 1/4th of the initial water volume. This standard reduction principle yielded 400 ml, 560 ml, and 800 ml of final *Kwatha* for Batches I, II, and III, respectively. The linear correlation between initial volumes and final yields confirms that this extraction method is highly reproducible and scalable across different batch sizes (Table 4).

Arka

The preparation of *Arka* was executed across three independent batches utilizing equal proportions (1 part each) of *Bakula*, *Twaka*, *Haritaki*, and *Musta* (Table 1). The raw material quantities were scaled progressively, using 20 ml, 50 ml, and 70 ml per ingredient for Batches I, II, and III, respectively. Water was introduced at a 2-part ratio, corresponding to 160+160 ml for Batch I, 400+400 ml for Batch II, and 560+560 ml for Batch III (Table 5)

Physical Observations

A highly consistent pattern of physical and thermal transitions was observed across all three experimental batches during the *Arka* process. Initial Stage: The starting mixture across all batches presented as a dark brown liquid containing coarsely powdered drugs, recorded at temperatures ranging from 26°C to 32°C.Thermal Transition: As the actual temperature increased (reaching 47°C in Batch I, 64°C in Batch II, and 60°C in Batch III), slight frothing became visible on the liquid surface. *Arka* Initiation: The collection of *Arka* commenced concurrently with the onset of

bubbling, which occurred at temperatures of 60°C (Batch I), 70°C (Batch II), and 68°C (Batch III).Peak Distillation (*Arka*): Marked bubbling was maintained as internal temperatures rose further into the 72°C–80°C range. Process Completion: The process concluded upon reaching *Gat Rasatva*, with final collection temperatures peaking at 78°C for Batch I, 80°C for Batch II, and 82°C for Batch III. The total duration required for complete extraction scaled with the batch volume, taking 50 minutes for Batch I, 1 hour 40 minutes for Batch II, and 2 hours 30 minutes for Batch III (Table 6, 7, 8& Figure 2). Final Yield The initial *Arka* volumes were recorded at 160 ml for Batch I, 400 ml for Batch II, and 560 ml for Batch III. Following the completion of the distillation cycle, the final recovered volumes of clear *Arka* were 105 ml, 248 ml, and 351 ml, respectively. These outcomes demonstrate a highly linear and reproducible distillation yield relative to the scale of the starting volume (Table 9).

Distillate:

The distillation process involved four primary ingredients—*Bakula*, *Twaka*, *Musta*, and Haritaki—combined in equal proportions of 1 part each alongside 10 parts of water (Table 1). For Batch I, 35 ml of each raw drug was mixed with 1400 ml of water. For the remaining two batch setups, 20 ml of each drug was combined with 800 ml of water (Table 10).

Physical Observations

Initial State: The baseline mixture across all three batches appeared as a brownish coloured liquid containing coarsely powdered drugs, recorded at temperatures between 26°C and 30°C. Frothing Phase: Initial thermal application triggered frothing at 60°C in Batch I and Batch II, and at 63°C in Batch III. This was followed by increased frothing and minor bubbling as temperatures rose. Collection Onset: Distillate collection began at an actual temperature of 67°C for Batch I and at 70°C for both Batch II and Batch III. Peak Distillation: Extended heating maintained marked bubbling across a temperature spectrum of 70°C to 85°C across the tracking periods. Process Termination: Heating was systematically terminated for all batches precisely when 60% of the distillate had been collected. This final collection stage was achieved at an actual temperature of 85°C for Batch I, 83°C for Batch II and 80°C for Batch III. (Table 11, 12, 13 and Figure 2) Final Yield Batch I began with an initial volume of 1400 ml and concluded with a final distillate volume of 840 ml. The subsequent batch columns started with an initial volume of 800 ml and both yielded a final distillate volume of 480 ml (Table 14). The final volumes confirm a highly uniform and mathematically consistent 60% recovery rate relative to the starting liquid volume across all experimental batches.

Standardization of finished products

Kwatha

The *Kwatha* presented as a brown-colored preparation with a characteristic odor and a distinctly pungent and astringent taste. Quantitative analysis yielded a pH of 3.62, a specific gravity of 1.0288, and a total solid content of 6.306% w/v.

Arka

The *Arka* presented as a transparent liquid characterized by a pleasant odor and a sweet yet pungent taste. Quantitative physico-chemical evaluation yielded a pH of 4.30, a specific gravity of 1.0102 w/w, and a trace total solid content of 0.004% w/v.

Distillate

The organoleptic evaluation of the distillate revealed it to be a transparent formulation characterized by a pleasant odor and a predominantly sweet and pungent taste. Further physico-chemical analysis was conducted to evaluate the quality of the distillate. The results yielded a pH value of 4.56, a specific gravity of 0.9964 w/w, and a negligible total solid content of 0.003% w/v.

Antimicrobial Profile

The experimental measurements for the zones of inhibition produced by the three distinct pharmaceutical mouthwash forms against the targeted microbial strains are presented in Table 15. The data indicates that the Polyherbal *Arka* formulation demonstrated the most consistent performance, establishing a uniform 5.0 mm zone of

inhibition across all four bacterial strains, including both Gram-positive and Gram-negative organisms. The Polyherbal Distillate showed weak activity, producing a minimal 3.0 mm zone of inhibition across the entire panel. The Polyherbal *Kwatha* achieved only a 3.0 mm zone against *Streptococci* and *Staphylococcus aureus*, while failing to show any inhibitory activity against *Escherichia coli* and *Klebsiella pneumoniae*, indicating complete resistance under these experimental conditions. (Graph 1 and Table 15).

DISCUSSION

The comparative experimental data highlights the significant influence of pharmaceutical processing methodologies on the antimicrobial properties of polyherbal formulations. While identical ratios of *Mimusops elengi*, *Cinnamomum zeylanicum*, *Cyperus rotundus* and *Terminalia chebula* were maintained across all batches, their antibacterial efficacy varied markedly depending on the preparation method (*Arka*, *Kwatha*, or Distillate). The superior and consistent performance of the *Arka* preparation can be attributed to the physics of hydro-distillation. This process effectively co-distils volatile lipophilic secondary metabolites alongside water vapour. Elements such as cinnamaldehyde from *Cinnamomum zeylanicum* and specific terpenoid fractions from *Mimusops elengi* and *Cyperus rotundus* are vaporized and condensed into a stable,homogenous aqueous phase.[26] These volatile compounds can disrupt bacterial cytoplasmic membranes, increase permeability and induce cell death. In contrast, simple steam distillation (*Distillate*) appeared less effective at extracting these active fractions under the parameters tested, resulting in lower antimicrobial activity (3.0 mm ZOI). The poor in-vitro performance of the *Kwatha* (decoction) requires careful analysis. In classical Ayurveda clinical practice, *Kwatha* is routinely prescribed for use in a warm or hot state (*Sukhoshna*). This elevated temperature maintains the solubility of large, complex compounds such as the polyphenols and condensed tannins found in *Terminalia chebula* and *Mimusops elengi*. However, standard in-vitro disk diffusion assays are conducted at room temperature, causing the *Kwatha* to cool during plate application. This cooling can precipitate dense macromolecular complexes, reducing their outward radial diffusion through the agar matrix and resulting in a smaller or absent zone of inhibition. This finding highlights a methodological limitation of standard agar diffusion tests for evaluating dense, non-volatile traditional extracts.

To properly contextualize these findings within contemporary dental medicine, it is valuable to evaluate them alongside global clinical data. Worldwide, 0.2% chlorhexidine gluconate remains the gold standard for chemical plaque control due to its strong cationic binding to oral surfaces. However, its long-term use is restricted by tooth discoloration, taste alterations, and mucosal desquamation. Recent global clinical trials confirm thatnatural polyherbal mouthwashes can offer comparable clinical efficacy without these adverse effects.[27] For example, a randomized clinical trial by demonstrated that an all-natural polyherbal mouthwash significantly reduced full-mouth plaque and bleeding scores over a three-month period, demonstrating therapeutic efficacy comparable to standard protocols while maintaining high safety profiles.[28] Indeed, the transition toward such biocompatible formulations is increasingly motivated by the clinical imperative to mitigate the common side effects associated with chlorhexidine-based regimens [29]. Furthermore, *Triphala* has emerged as a particularly viable alternative, demonstrating a lack of adverse side effects and superior patient satisfaction in comparison to the metallic taste and soreness frequently reported by chlorhexidine users. [30] Similarly, a randomized non-inferiority clinical trial demonstrated that traditional herbal mouthwashes can match chlorhexidine in reducing anti-gingivitis and anti-plaque indices[31],as well as significantly lowering bacterial counts of key periodontal pathogens like *Porphyromonas gingivalis*.[32]Clinical evaluations also confirmed that natural preparations function effectively as adjuvants to scaling, showing a significant reduction in aerobic colony-forming units (CFUs) comparable to chemical counter-agents.[33]

Furthermore, recent advances in molecular sequencing have revealed insights into how mouthwashes affect the broader oral microbiome. A randomized, double-blind trial utilized 16S rRNA sequencing to compare the effects of chlorhexidine against a polyherbal formulation.[34] The study revealed that while chlorhexidine possesses strong antimicrobial activity, its formulation can disrupt microbial diversity, leading to dysbiosis and an increase in

potentially opportunistic genera. In contrast, the polyherbal formulation selectively modulated the oral ecosystem, preserving overall microbial diversity and stability while achieving high patient acceptability in taste, comfort and moisture retention. This aligns with findings high patient satisfaction and clinical efficacy for alternative herbal mouth rinses.[35]The *Arka* formulation demonstrated reliable antimicrobial activity; however, its effects on the oral microbiome remain to be established through dedicated microbiome studies.

Limitations of the Study

The present study evaluated the antimicrobial activity of the developed polyherbal mouthwash against a representative panel of bacterial species and therefore does not encompass the full diversity of the oral microbiome. Important oral pathogens such as *Streptococcusmutans*, *Porphyromonas gingivalis*, *Fusobacterium nucleatum*, *Aggregatibacter actinomycetemcomitans* and *Candidaalbicans* were not included. Moreover, the observed zones of inhibition were lower than those generally reported for chlorhexidine, which is expected because polyherbal formulations contain complex phytochemical mixtures with limited agar diffusion compared with purified synthetic antiseptics. The primary objective of this investigation was to compare different Ayurvedic pharmaceutical processing methods rather than to establish equivalence with chlorhexidine. Therefore, further studies involving MIC/MBC determination, biofilm and time-kill assays, phytochemical standardization, and well-designed in vivo clinical trials are required to comprehensively establish the antimicrobial efficacy and clinical applicability of the developed polyherbal mouthwash.

CONCLUSION

The present study successfully validates the pharmaceutical development of an Ayurveda polyherbal mouthwash, demonstrating that the chosen extraction methodology significantly dictates the final antimicrobial efficacy of the mixture. By comparatively evaluating three distinct traditional preparations, this research establishes that the hydro-distilled *Arka*formulation is the superior dosage form for modern dental applications. The *Arka* formulation delivered a uniform broad-spectrum antimicrobial response (producing a consistent 5.0 mm zone of inhibition) against both Gram-positive (*Streptococci*, *S. aureus*) and Gram-negative (*E. coli*, *K. pneumoniae*) pathogens. The traditional aqueous *Kwatha* displayed limited to no efficacy under standardized room-temperature testing conditions, highlighting a critical diffusion limitation of dense macromolecular complexes when not administered in their classical warm (*Sukhoshna*) state. This research supports the modernization of traditional Ayurveda pharmacology into ready-to-use platforms. Future in-vivo clinical trials and comprehensive microbiome sequencing are highly recommended to further establish the therapeutic equivalence and long-term ecological benefits of this *Arka* mouthwash in routine clinical dental practice.

ABSTRACT

Infertility is experienced by 10–15% of couples, and female factors cause half of them. Uterine pathology, tubal pathology, and conditions such as endometriosis are frequent etiologies. Conventional imaging methods, although good, are invasive and expensive. Multi detector CT virtual hysteroscopy (MDCT-VH) provides a less invasive, high-fidelity 3D imaging option with the possibility of diagnosing uterine and tubal pathology. The purpose of this review is to assess the validity and clinical value of MDCT-VH in diagnosing infertility in women. More specifically, it determines the sensitivity and specificity of MDCT-VH in the diagnosis of tubal pathology, reviews its advantages in overall imaging of the female reproductive system, and compares its diagnostic capability with conventional imaging techniques such as ultrasound and MRI. A PRISMA-informed systematic review was done applying Scopus, PubMed, and Web of Science studies (2010–2025), and MDCT-VH's efficacy in diagnosing infertility disorders. MDCT-VH has high diagnostic efficiency, with sensitivity ranging up to 99.2% and specificity ranging up to 98%. MDCT-VH is complete reproductive imaging, usually superior to conventional methods such as HSG, and supplements MRI, ultrasound, and hysteroscopy in depicting tubal, uterine, and cervical pathology. MDCT-VH is a cost-effective diagnostic option for female infertility, particularly for tubal and high-resolution anatomical imaging. Although it is supplementary to other techniques, it enhances diagnostic accuracy and supports the management of infertility.

Keywords: Female infertility, Multi detector CT, Virtual hysteroscopy, Diagnostic accuracy, Uterine abnormalities, Non-invasive imaging.

INTRODUCTION

Infertility is present in 10–15% of couples worldwide, and female etiology accounts for 50% of the cases [1,2]. Infertility not only adversely affects conception but also imposes heavy psychological, emotional, and social burdens [3]. Infertility treatment is costly, and couples undergo many medical examinations, fertility treatments, and assisted reproductive technologies (ART), most of which are costly and not readily available. Proper diagnosis and management rely heavily on a complete knowledge of female causes of infertility. Uterine, tubal, and peritoneal pathology are frequent reasons for female infertility, with unique pathologies that interfere with conception or maintenance of pregnancy[2,4]. Accurate and early diagnosis is important in order to maximize fertility results4.Uterine pathology is responsible for 10–15% of infertility [2,4] and can be congenital, such as Müllerian anomalies (e.g., septate, bicornuate uteri), or acquired, such as fibroids, adenomyosis, endometrial polyps, and intrauterine adhesions (Asherman's syndrome) [3]. Submucosal fibroids and endometrial polyps may interfere with implantation and result in infertility[5]. Imaging modalities like transvaginal ultrasonography, saline infusion sonography (SIS), MRI, and hysteroscopy are usually employed in the identification of uterine abnormalities4.Tubal factor infertility due to conditions such as pelvic inflammatory disease (PID) or endometriosis accounts for 25–35% of infertility[2]. Tubal impairment, e.g., scarring or PID occlusion, may be the cause of failure of fertilization6. Testing of tubal function using methods such as hysterosalpingography (HSG), laparoscopy, and CT virtual hysterosalpingography (CT-VHSG) is important in diagnosis6,7.Peritoneal factor infertility, in many cases linked to endometriosis or pelvic adhesions, is more difficult to establish by conventional imaging [2,4]. Laparoscopy is still the 'gold standard' for the diagnosis of these conditions, though MRI and MDCT-based virtual hysterosalpingography can generate valuable additional information[4].Female infertility is assessed with a variety of imaging modalities, such as ultrasonography, SIS, HSG, MRI, and laparoscopy. These methods, employed together, give an overall evaluation of the uterine, tubal, and peritoneal causes[3]. MDCT, particularly employed for virtual hysterosalpingography, provides a non-invasive, high-resolution 3D imaging option over traditional techniques. It permits examination of both uterine and tubal anatomy and is possibly more comfortable and faster for patients, providing useful information that may minimize the necessity for further invasive procedures [7,8]

Aim and Objectives

The aim of this study is to evaluate the efficacy of multidetector CT virtual hysteroscopy (MDCT-VH) in diagnosing female infertility through a systematic review. Specifically, the objectives include assessing the sensitivity and specificity of MDCT-VH in detecting tubal diseases associated with infertility, evaluating its benefits in providing comprehensive imaging of the female reproductive system, and comparing its diagnostic outcomes with conventional imaging techniques such as ultrasound and MRI in infertility cases.

MATERIALS AND METHODS

A retrospective observational study was carried out at the Department of Radio-Imaging Technology, SGT University, Gurugram, Haryana, to evaluate the efficiency of multi detector CT virtual hysteroscopy (MDCT-VH) in the diagnosis of female infertility. The study evaluated 50 peer-reviewed research articles published in English language from January to May 2025.

Selection Criteria

Inclusion criteria

The study evaluated the use of MDCT-VH in diagnosing female infertility by reviewing published, peer-reviewed articles from Scopus, PubMed, and UGC Care Journals. Only human studies that provided specific diagnostic criteria for female infertility were included in the analysis.

Exclusion criteria

The study excluded non-English articles, animal studies, and conference abstracts, as well as studies with unclear diagnostic criteria or outcomes. Duplicate publications and those with inadequate data for analysis were also excluded from the review.

Statistical Analysis

Statistical examination was done following PRISMA principles. A random effects model was applied to estimate MDCT-VH's sensitivity, specificity, and predictive values combined. Comparative accuracy against conventional imaging methods was calculated where appropriate, and heterogeneity was measured using the I^2 statistic.

RESULTS

Multi detector CT virtual hysteroscopy (MDCT-VH) has been systematically reviewed for its effectiveness in diagnosing female infertility, particularly its sensitivity and specificity in detecting tubal pathologies, its ability to provide comprehensive anatomical views, and its diagnostic performance compared to traditional imaging methods.

MDCT-VH's Diagnostic Accuracy in Tubal Pathology

MDCT-VH and related CT methods demonstrate high diagnostic accuracy for assessing tubal patency and identifying pathologies. A meta-analysis reported CT-VHSG with a combined sensitivity of 0.992 and specificity of 0.98[10]. MDCT also showed excellent sensitivity (100%) and specificity (96.7%) for tubal block detection, comparable to hysterosalpingography (HSG)[11]. Another study found 128-MDCT VHSG 100% sensitive and 85.71% specific for fallopian tube pathology, with strong predictive values[12]. MDCT-VH compares favorably with HSG[13]. HSG has shown varying performance, with a reported 91.3% sensitivity and 88.9% specificity for tubal patency relative to laparoscopy[14]. However, HSG can have high sensitivity (90.91%) but lower specificity (77.78%) for tubal disease, sometimes requiring laparoscopy for confirmation [15]. An individual patient data meta-analysis found HSG's sensitivity and specificity for any tubal pathology to be 53% and 87% respectively, and for bilateral tubal pathology, 46% and 95%, with lower sensitivity in women without tubal disease risk factors[16]. These inconsistencies highlight MDCT-VH's more reliable diagnostic accuracy[10].

Advantages of MDCT-VH's Comprehensive Views

MDCT-VH offers a thorough assessment of the female reproductive system, providing detailed anatomical information beyond tubal patency. It improves diagnostic confidence via magnetic-resonance virtual hysterosalpingography (MR-VHSG) and computerized tomographic virtual hysterosalpingography (CT-VHSG) [17]. Its 2D, 3D, and virtual endoscopic imaging capabilities allow for a comprehensive examination of the cervix, fallopian tubes, uterine wall, uterine cavity, and para-uterine pelvic structures, a significant strength in infertility workup [18]. Sixty-four-row VHSG demonstrated excellent diagnostic accuracy for evaluating the uterus and female reproductive system. In a study of 2,500 patients, MDCT-VH accurately assessed internal female genital organs, detecting cervical abnormalities, uterine cavity pathology (e.g., polyps, myomas, synechiae, malformations, adenomyosis), and tubal obstruction, with a low mean radiation dose of 0.94 [19]. MDCT-VH's precise characterization of pathological processes makes it a valuable second-line diagnostic method, providing extensive information to gynecologists for improved therapeutic decisions [17,18].

MDCT-VH's Comparative Diagnostic Performance

MDCT-VH often outperforms and complements conventional imaging techniques like ultrasound (US) and MRI. It causes less patient discomfort and has a lower mean effective radiation dose compared to typical HSG. MDCT can also diagnose adenomyosis and ovarian tumors missed by HSG, though its inability to visualize pelvic adhesions due to lacking delayed imaging is a limitation HSG partially overcomes [11]. Virtual multislice CT hysterosalpingogram (VHSG) showed comparable diagnostic precision to multi parametric MRI-HSG for ovarian and extrauterine abnormalities, uterine morphology, and tubal patency, with high specificity (95.2%) and sensitivity (97.7%)[20]. This

suggests MDCT-VH is as effective as sophisticated MRI for various infertility conditions. Similarly, conventional HSG and MR HSG show comparable diagnostic value for tubal patency, supporting the efficacy of non-radiation-based technologies [21]. While MDCT-VH offers comprehensive views, other modalities excel in specific areas. TVS is preferred for myometrial pathology, HSG for tubal pathologies, and hysteroscopy (HSC) for endometrial pathologies [22]. TVS is more appropriate for myometrial and endometrial lesions, while HSG is better for obliterative uterine cavity disorders [23]. A multimodal approach is therefore often optimal, with MDCT-VH complementing other techniques. Advanced CT, such as virtual monoenergetic imaging (VMI) from dual-energy computed tomography (DECT), shows promise for uterine pathologies beyond infertility, demonstrating greater sensitivity for myometrial invasion than standard CT and MRI in endometrial cancer [24].

General Efficacy and Role of Hysteroscopy in Infertility Diagnosis

Hysteroscopy is crucial for diagnosing female infertility and is often considered the gold standard for direct viewing and precise treatment of intrauterine lesions[25,26]. It effectively identifies and manages disorders such as uterine septum, intrauterine adhesions, endometrial polyps, and submucous myomas [26,27]. Hysteroscopy consistently demonstrates superiority over other techniques for uterine cavity evaluation. It identified incidental findings in 15.38% of cases not seen with HSG, leading to recommendations for its routine use in infertile patients [28]. Saline infusion sonohysterography (SIS) showed 81.2% sensitivity, 86.9% specificity, and 86.5% accuracy compared to hysteroscopy, suggesting it as an alternative when hysteroscopy is unavailable[29]. However, hysteroscopy remains the gold standard for diagnosing submucosal myomas, despite moderate agreement with hysterosonography[30]. TVS, HSG, and hysteroscopy are complementary, but hysteroscopy more accurately diagnoses and treats small intrauterine lesions[31]. It is 30% more effective than ultrasound in identifying uterine anomalies, even in patients with normal ultrasound reports[32], and is superior to histopathology for detecting intracavitary lesions[33]. Hysteroscopy significantly impacts fertility outcomes, particularly with ART. Evidence indicates it increases clinical pregnancy rate (CPR) and live birth rate (LBR) in infertile women, especially those with previous implantation failure[34]. Diagnostic hysteroscopy before the first IVF cycle may optimize the uterine environment[35]. Outpatient hysteroscopy can increase live birth and clinical pregnancy rates among infertile women on ART, even with normal initial imaging[36]. Specifically, hysteroscopic polypectomy improved IVF outcomes in patients with unexplained infertility and a history of unsuccessful IVF cycles[37].

Hysterolaparoscopy is highly effective, providing both a summary of pelvic reproductive anatomy and close-up images, often detecting correctable abnormalities overlooked by other modalities[38]. It is valuable for diagnosing and managing tuboperitoneal and intrauterine pathologies [39,40] and leads to better pregnancy outcomes in female infertility assessment and management41. Specific pathologies addressed in studies include elusive uterine lesions, morphological abnormalities, adenomyosis, and chronic endometritis, which negatively affect fertility[42]. Hysteroscopy shows good specificity and accuracy for diagnosing chronic endometritis [43]. Chromohysteroscopy significantly improves endometrial pathology diagnosis accuracy (92%) over routine hysteroscopy (58%) [44]. In terms of patient experience and safety, MDCT causes considerably less discomfort than HSG [11]. Pain during hysteroscopy with local anesthetic is generally low, with cervical canal passage being the most painful phase[45]. Cervical ripening techniques, such as vaginal estradiol and misoprostol pretreatment, minimize complications in operative hysteroscopy[46,47]. Office hysteroscopy successfully treats cervical stenosis in 98.5% of cases, significantly minimizing failed procedure [48]. A previous history of hysteroscopy does not adversely affect subsequent pregnancy outcomes like miscarriage or preterm delivery [49]. Literature also explores less frequent or specialized uses. MDCT venography aids in diagnosing pelvic congestion syndrome [50]. Traditional MRI is compared with 3D ultrasound for predicting ablation rates in uterine fibroids [51]. Hysteroscopy is compared with histopathological results in PCOS-related infertility [52]. Ultrasound and MRI characterize uterine cavities in women with unusual bleeding and extragenital pathology [53]. Hysteroscopy is key for diagnosing female genital tuberculosis, with high pregnancy outcomes after treatment for latent endometrial tuberculosis [54–56].

Diagnostic methods continue to evolve. Disposable digital hysteroscopes are useful and efficient for outpatient hysteroscopy [57].Negative intrauterine contrast-enhanced ultrasonography and multimodal hysterosalpingo-

contrast sonography enhance diagnostic efficiency for uterine lesions and tubal patency [58]. Recent outpatient tubal patency techniques with high negative predictive values are proposed as first-line options [59].

DISCUSSION

This systematic review evaluated the role of multi detector CT virtual hysteroscopy (MDCT-VH) in diagnosing female infertility, with a focus on its ability to identify tubal pathology, provide high-resolution imaging, and compare its effectiveness with traditional diagnostic techniques such as MRI, transvaginal ultrasonography (TVS), and hysterosalpingography (HSG). MDCT-VH has been recognized as a valuable non-invasive tool, offering superior anatomical visualization and enhancing patient comfort [60]. Tubal disease is a major contributor to infertility, and precise identification of conditions like tubal obstructions, hydrosalpinx, and pelvic adhesions is crucial for guiding treatment. MDCT-VH has demonstrated high sensitivity and specificity in detecting tubal pathologies, performing on par with or better than conventional HSG [11,60]. Unlike HSG, which carries risks of patient discomfort and poor visualization of pelvic structures, MDCT-VH provides a clear assessment of the fallopian tubes and pelvic environment in a single session, avoiding invasive procedures [61]. Moreover, it allows the detection of extratubal pathologies, such as pelvic adhesions or endometriosis, which can also impact fertility [60].

MDCT-VH offers a significant advantage with its ability to produce high-resolution, multi-planar, and 3D images of the entire reproductive system, including the uterine cavity, cervix, and surrounding pelvic structures [17].The technique's virtual hysteroscopic images provide a clear view of uterine anomalies, such as polyps, fibroids, and adhesions, which are often missed by less sensitive imaging methods[42]. This comprehensive evaluation of both intra-uterine and extra-uterine structures is particularly beneficial for complex infertility cases [17]. Despite its many benefits, MDCT-VH is not a replacement for other diagnostic modalities but rather a complement. Hysteroscopy remains the gold standard for visualizing and treating intrauterine pathology due to its ability to provide direct visibility and enable immediate intervention [61]. Transvaginal ultrasound, with its non-invasive nature and ability to assess ovarian reserve and myometrial pathology, remains indispensable, especially in low-cost settings [17]. MRI is essential for assessing complex pelvic conditions like deep infiltrating endometriosis, where its superior soft tissue resolution is critical [11]. Integrating MDCT-VH into the diagnostic pathway alongside these established techniques provides a holistic approach to infertility diagnosis, addressing its multifactorial nature [60]. MDCT-VH is also advantageous from a patient-centered perspective, as it is less invasive and more comfortable compared to HSG and hysteroscopy, which involve cervical instrumentation and can be quite uncomfortable [42,60]. Patients generally accept MDCT-VH due to its rapid, non-anesthetic nature, reducing anxiety during the infertility workup [42]. Additionally, advances in multidetector CT technology have significantly reduced radiation exposure, addressing previous concerns about ionizing radiation in reproductive-age women, though adherence to radiation safety protocols remains critical [17].

However, MDCT-VH does have limitations. Despite advancements in reducing radiation doses, it still involves ionizing radiation, which poses a risk, particularly for patients requiring multiple imaging sessions during infertility evaluations [42]. Furthermore, MDCT-VH lacks therapeutic capabilities, necessitating additional procedures if abnormalities are detected. Cost and accessibility may limit its use in resource-constrained settings, and the variability in operator expertise and imaging protocols highlights the need for standardization to ensure diagnostic accuracy [11]. Overcoming these challenges through improved technical training and protocol optimization will be essential for wider clinical adoption [11]. Future research should focus on refining MDCT-VH protocols to further reduce radiation doses and improve image quality. The development of consensus guidelines and reporting standards will enhance comparability across studies and clinical practices. Additionally, integrating artificial intelligence for automated image interpretation could enhance diagnostic precision and reduce operator dependency. Long-term studies evaluating the impact of MDCT-VH on fertility outcomes and cost-effectiveness are needed to establish its place in infertility treatment [42].

CONCLUSION

This review highlights multidetector computed tomography virtual hysteroscopy (MDCT-VH) as a very powerful, less invasive diagnostic tool for female infertility. It yields better tubal abnormality detection, including obstruction and hydrosalpinx, than conventional hysterosalpingography (HSG) without HSG's limitations such as patient discomfort and restricted pelvic visualization. MDCT-VH provides excellent imaging of both intrauterine and extra-uterine pathology, facilitating better diagnosis and treatment planning. Nevertheless, MDCT-VH must supplement, rather than substitute, other techniques such as hysteroscopy, MRI, and TVS. Although its radiation burden has decreased with advances in technology, issues of exposure, expense, and standardization protocols persist. Future studies must aim to maximize imaging protocols, minimize radiation, and incorporate artificial intelligence. In conclusion, MDCT-VH improves infertility diagnosis and treatment, providing accurate anatomical views and increased patient comfort when combined with conventional modalities.

ABSTRACT

As water becomes a scarce material every day, there is an urgent need to explore ways to save water in concrete production and buildings. Curing of concrete is the maintenance of satisfactory moisture content of concrete in its initial stage to develop the desired properties. However, good healing is not always practical in many cases. Hardening of concrete plays an important role in the formation of the microstructure and pore structure of concrete and thus improves its durability and performance. Considering this importance, efforts have been made to develop self-hardening concrete using self-hardening water-soluble polyethylene glycol as granite and lightweight aggregate. The purpose of this research is to find out the strength and durability properties of concrete using water-soluble polyethylene glycol as a self-hardening agent. The task of self-hardening substances is to reduce the evaporation of water from the concrete, and thus they increase the water resistance of concrete compared to conventionally hardened concrete. The use of self-hardening additives is very important from the point of view that saving water is necessary every day (3m^3 of water is used in the building for every cubic meter of concrete, most of which is used for stoning). In this work, the compressive and fracture strengths

of concrete containing self-hardening substances are investigated and compared with those of conventionally hardened concrete. In this experimental study, concrete cast with polyethylene glycol as a self-hardening agent was found to be stronger than concrete obtained by spray or immersion curing. In this study, the effect of an additive (PEG 400) on compressive strength, crack tensile strength and fracture layer was investigated for M_{20} by varying the percentage of PEG by weight of cement between 0% and 2%. It was found that PEG 400 can help in self-healing, providing similar strength to conventional healing. It was also found that 1% PEG 400 cement was optimal for M_{20} grade concretes to achieve maximum strength without compromising workability.

Keywords: PEG (Polyethylene Glycol), M_{20}Grade Concrete, PEG 400, W/C Ratio, Hardening Properties.

INTRODUCTION

Curing is the process of maintaining proper moisture content particularly within 28 days to promote optimum cement hydration immediately after placement. Curing plays a major role in developing the concrete microstructure and pore structure. Good curing is not practically possible in most of the cases. The self-curing concrete means that no external curing required for concrete.

General

Curing is the name given to the procedures used for promoting the hydration of the cement, and consists of a control of temperature and of moisture movement from and into the concrete. Curing allows continuous hydration of cement and consequently continuous gain in the strength, once curing stops strength gain of the concrete also stops. Proper moisture conditions are critical because the hydration of the cement virtually ceases when the relative humidity with in the capillaries drops below 80%. Proper curing of concrete structures is important to meet performance and durability requirements. In conventional curing this is achieved by external curing applied after mixing, placing and finishing. Self-curing or internal curing is a technique that can be used to provide additional moisture in concrete for more effective hydration of cement and reduced self-desiccation. When concrete is exposed to the environment evaporation of water takes place and loss of moisture will reduce the initial water cement ratio which will result in the incomplete hydration of the cement and hence lowering the quality of the concrete.

Various factors such as wind velocity, relative humidity, atmospheric temperature, water cement ratio of the mix and type of the cement used in the mix. Evaporation in the initial stage leads to plastic shrinkage cracking and at the final stage of setting it leads to drying shrinkage cracking. Curing temperature is one of the major factors that affect the strength development rate. At elevated temperature ordinary concrete losses its strength due to the formation of the cracks between two thermally incompatible ingredients, cement paste and aggregates. Concrete is the most widely used building material. It has the characteristic of being formed into desired shape most conveniently. It is an artificial material consisting of ingredients such as cement, fine aggregates, coarse aggregates and water. Aggregates are the major ingredients of concrete. Any construction activity requires several materials such as concrete, steel bricks, stone, glass clay, mud, wood and so on. For its sustainability and adaptability with respect to the changing environment the concrete must be such that it can converse resources protected environment, economize and lead to proper utilization of energy. Plain concrete possesses a very low tensile strength, limited ductility, and little resistance cracking. Internal micro cracks are inherently present in the concrete and its poor tensile strength is due to the propagation of such micro cracks, eventually leading to brittle failure of the concrete.

The most widely accepted remedy to this flexural weakness of concrete is the conventional reinforcement with high strength steel. Also, the reinforcement placing and efficient compaction of RCC is very difficult if the concrete is of low workability especially in the case of concrete. In plain concrete and similar brittle materials, structural cracks (micro- cracks) develop even before loading, particularly due to dying shrinkage or other causes of volume changes.

curing of concrete is important to ensure they meet their performance and intended durability requirements. Internal Curing (IC) is a very promising technique that can provide additional moisture in concrete for a more effective hydration of the cement. During hydration of cement, empty pores are created within the cement paste, leading to a reduction in its internal relative humidity and cause cracks to develop at the early-age. This situation is intensified in HPC which can be solved by using the self- curing agents like `super-absorbent polymers` they can retain the moisture for a long period of time. The ACI-308 Code states that Internal Curing refers to the process by which the hydration of cement occurs because of the availability of additional internal water that is not part of the mixing water. Conventionally, curing concrete means creating conditions such that water is not lost from the surface i.e., curing is taken to happen from the outside to inside. In contrast, internal curing is allowing for curing from the inside to outside through the internal reservoirs (superabsorbent polymers) created. Internal curing "is often also referred as Self–curing".

Concrete

Concrete is a composite construction material composed of cement (commonly Portland cement) and other cementious materials such as fly ash and slag cement, aggregate (generally a coarse aggregate made of gravels or crushed rocks such as limestone, or granite, plus a fine aggregate such as sand), water, and chemical admixtures. Concrete solidifies and hardens after mixing with water and placement due to a chemical process known as hydration. The water reacts with the cement, which bonds the other components together, eventually creating a robust stone-like material. Concrete is used to make pavements, pipe, architectural structures, foundations, and motorways/roads, bridges/overpasses, parking structures, brick/block walls and footings for gates, fences and poles.
Concrete is used more than any other manmade material in the world. As of 2006, about 7.5 cubic kilometres of concrete are made each year more than one cubic meter for every person on Earth.

Self Curing:

Internal curing refers to the process by which the hydration of cement occurs because of the availability of additional internal water that is not part of the mixing water. Benefits of internal curing include increased hydration and strength development, reduced autogenous shrinkage and cracking, reduced permeability and increased durability. Internal curing distributes extra water throughout the entire microstructure, thus maintaining saturation of the cement paste during hydration. However, good curing is not always practical and often neglected in many cases. Conventional concrete was found that water soluble alcohols can be used as self-curing agents in concrete. The use of self-curing admixtures is very important from the point of view that water recourse's are getting valuable every day. Self-curing or internal curing is a technique that can be used to provide additional moisture in concrete for more effective hydration of cement and reduced self - desiccation. The benefits of self-curing admixtures is more significant in desert areas where water is not adequately available.

Definition of Self-Curing

The ACI-308 Code states that self-curing refers to the process by which the hydration of cement occurs because of the availability of additional internal water that is not part of the mixing Water. Conventionally, curing concrete means creating conditions such that water is not lost from the surface i.e., curing is taken to happen from the outside to inside'. In contrast, self-curing is allowing for curing from the inside to outside through the internal reservoirs (in the form of saturated Lightweight fine aggregates, superabsorbent polymers, or saturated wood fibers) created. Self-curing is often also referred as Internal–curing.

Potential Materials For Self Curing

The following materials can provide internal water reservoirs

- Lightweight Aggregate (natural and synthetic, expanded shale),
- LWS Sand (Water absorption =17 %)
- LWA 19mm Coarse (Water absorption = 20%)

- Super-absorbent Polymers (SAP) (60-300 mm size)
- SRA (Shrinkage Reducing Admixture) (propylene glycol type i.e. polyethylene-glycol) Wood powder

Chemicals To Achieve Self–Curing

Some specific water-soluble chemicals added during the mixing can reduce water evaporation from and within the set concrete, making it self- curing. The chemicals should have abilities to reduce evaporation from solution and to improve water retention in ordinary Portland cement matrix.

Water Required For Self–Curing

It depends upon chemical and autogenous shrinkages expected during hydration reactions. Types of Shrinkage Drying Shrinkages may occur at early ages or at later ages over a longer period; different types of shrinkages may be identified as: Drying shrinkage, autogenous shrinkage, thermal shrinkage, and carbonation shrinkage.

Reason For Chemical Shrinkage

Chemical shrinkage is an internal volume reduction due to the absolute volume of the hydration Products being less than that of the reactants (cement and water). For example: Hydration of tricalcium silicate:

$C3S + 5.3\ H > C1.7SH4 + 1.3\ CH$

Need For Self–Curing

When the mineral admixtures react completely in a blended cement system, their demand for curing water (external or internal) can be much greater than that in a conventional ordinary Portland cement concrete. When this water is not readily available, due to Depercolation of the capillary porosity, for example, significant autogenous deformation and (early- age) cracking may result. Due to the chemical shrinkage occurring during cement hydration, empty pores are created within the cement paste, leading to a reduction in its internal relative humidity and also to shrinkage which may cause early-age cracking. This situation is intensified in HPC (compared to conventional concrete) due to its generally higher cement content, reduced water/cement (w/c) ratio and the pozzolanic mineral admixtures (fly ash, silica fume). The empty pores created during self-desiccation induce shrinkage stresses and also influence the kinetics of cement hydration process, limiting the final degree of hydration. The strength achieved by IC could be more than that possible under saturated curing conditions. Often specially in HPC, it is not easily possible to provide curing water from the top surface at the rate required to satisfy the on-going chemical shrinkage, due to the extreme.

Necessity of Self Curing

Conventionally, curing concrete means creating conditions such that water is not lost from the surface i.e., curing is taken to happen from the outside to inside. In contrast internal curing is allowing for curing from the inside to outside. Self-curing is also referred as internal curing.

Self-Curing Concrete

The concept of curing and recognition of its contribution to obtain desirable properties of concrete is not novel. This technique has been adopted to maintain moisture and temperature conditions in a freshly placed cementious mixture to allow hydraulic cement hydration and pozzolanic reactions to occur so that the potential properties of the mixture may develop. In earlier stage though it has not received proper attention but nowadays it is found to be one of major concern in the study of concrete performance. However the concept of self-curing has been developed and now been in practice to eliminate some problems occurred in case of traditional curing. According to the definition provided in American Concrete Institute (ACI) Terminology guide self-curing is supplying water throughout a freshly placed cementious mixture using reservoirs, via pre-wetted lightweight aggregates, that readily release water as needed for hydration or to replace moisture lost through evaporation or self-desiccation (American Concrete Institute.2010).

The principal contribution of self-curing results in the reduction of permeability that develops from a significant extension in the time of curing. Self-curing reduces plastic shrinkage cracking and settlement. Also a life-cycle cost

reduction was estimated when internally cured high performance concrete is used instead of normal concrete. So far different materials has been self-curing such as Super Absorbent Polymers (SAP), Wood Powder, crushed return concrete aggregates, rewetted Light Weight Aggregates (LWA) expanded shale, clays, and slates.

Improvements To Concrete Due To Self-Curing:

- Reduces autogenous cracking
- Reduces permeability
- Protects reinforcing steel
- Increases mortar strength
- Provides greater durability
- Higher early age flexural strength
- Higher early age compressive strength
- Higher modulus of elasticity

Need And Scope of Study

Curing of concrete is maintaining satisfactory moisture content in concrete during its early stages in order to develop the desired properties. However good curing is not always practical in many cases. The aim of this investigation is to evaluate the use of water-soluble polymeric glycol as self-curing agents. The use of self-curing admixture curing admixtures is very important from the point of view that the water resources are getting valuable every day. The benefit of self -curing admixtures is more significant in desert areas where water is not adequately available. In this study the mechanical properties of self-curing at different percentages of poly ethylene glycol will be evaluated and compared with conventional concrete specimen.Scope of the study is to identify the effect of Polyethylene Glycol (PEG) on strength characteristics of self-curing concrete and also to evaluate influence of poly ethylene glycol on mechanical properties which are experimentally investigated.

Mechanism And Significance of Self Curing Concrete

Continuous evaporation of moisture takes place from an exposed surface due to the difference in chemical potentials (Free energy) between the vapour and liquid phases. The polymers added in the mix mainly form hydrogen bonds with water molecules and reduce the chemical potential of the molecules which in turn reduces the vapour pressure, thus reducing the rate of evaporation from the surface. When the mineral admixtures react completely in a blended cement system, their demand for curing water (external or internal) can be much greater than that in a conventional ordinary Portland cement concrete. When this water is not readily available, significant autogenous deformation and (early-age) cracking may result. Due to the chemical shrinkage occurring during cement hydration, empty pores are created within the cement paste, leading to a reduction in its internal relative humidity and also to shrinkage which may cause early-age cracking.

Advantages of Self-Curing Concrete:

- Reduces autogenously cracking.
- self-curing
- Reduce the permeability.
- Increases mortar strength and early age strength sufficient to withstand strain.
- Greater utilization of cement.
- Lower Maintenances.

Advantages of Internal Curing

- Internal curing (IC) is a method to provide the water to hydrate all the cement, accomplishing what the mixing water alone cannot do. In low w/c ratio mixes (under 0.43 and increasingly those below 0.40) absorptive

lightweight aggregate, replacing some of the sand, provides water that is desorbed into the mortar fraction (paste) to be used as additional curing water. The cement, not hydrated by low amount of mixing water, will have more water available to it

- IC provides water to keep the relative humidity (RH) high, keeping self-desiccation from occurring.
- IC eliminates largely autogenous shrinkage.
- IC maintains the strengths of mortar/concrete at the early age (12 to 72 hrs.) above the level where internally & externally induced strains can cause cracking.
- IC can make up for some of the deficiencies of external curing, both human related (critical period when curing is required is the first 12 to 72 hours) and hydration related (because hydration products clog the passageways needed for the fluid curing water to travel to the cement particles thirsting for water).

Following factors establish the dynamics of water movement to the unhydrated cement particles:

- Thirst for water by the hydrating cement particles is very intense,
- Capillary action of the pores in the concrete is very strong, and
- Water in the properly distributed particles of LWA (fine) is very fluid.

Polyethylene Glycol

Introduction

Polyethylene Glycol (PEG) is family of water-soluble linear polymers formed by the additional reaction of Ethylene Oxide (EO) with Monoethylene Glycols (MEG) or Ethylene Glycol. The generalized formula for polyethylene glycol is: H− (O−CH2−CH2) n−OH. It is a polyether compound with many applications from industrial manufacturing to medicine. PEG is also known as **Polyethylene Oxide** (**PEO**) or **Polyoxy Ethylene** (**POE**), depending on its molecular weight. There are many grades of PEGs that represents them by their average molecular weight. For example, PEG 4000 consists of a distribution of polymers of varying molecular weight with an average of 4000. Polyethylene glycols are available in average molecular weight ranging from 200 to 8000 this wide range of products provides flexibility in choosing properties to meet the requirements of many different applications. One common feature of PEG appears to be the water-soluble nature. Poly ethylene glycol is non-toxic, odorless, neutral, lubricating, non-volatile, non – irritating and is used in a variety of pharmaceuticals. The most common which is mono-functional methyl ether PEG (Methoxy polyethylene glycol), abbreviated Mpeg. PEGs are also available with difference geometrics. Branched PEGs have 3 to 10 PEG chains emanating from a central core group. Star PEGs have 10-100 PEG chains emanating from a central core group. Comb PEGs have melting points vary depending on the formula weight of the polymer. PEG or PEO has the following structure: HO- (CH_2-CH_2-O-)$_n$-H.

The Most Important Physical Property

Depend on molecular weight the wide range of the physical property such as solubility, hygroscopic, vapour pressure, melting or freezing point and viscosity are variable:

- **Solubility:** Increasing the molecular weight of PEGs results in decreasing solubility in water & solvents. PEGs are also soluble in many polar organic solvents such as acetone, alcohols.
- **Hygroscopic:** PEGs are hygroscopic, it means that they attract and retain moisture from the atmosphere. Hygroscopic decreases as molecular weight increases.
- **Viscosity:** PEGs can be considered Newtonian fluids, so the kinematic viscosity of PEGs decrease as temperature increases.
- **Stability:** PEGs have low volatility and are thermally stable for limited period of time below 300°c and without o_2. Depending on their average molecular weight, the polyethylene glycol may be liquid or solid. PEG grades: 200,300,400,600 in liquid form PEG 1000,1500 soft solid(white) and PEG 2000,3000,4000,6000,8000 hard solid (white).

Applications

Pharmaceuticals: PEG grades meet requirements of USP/NF and BP and widely use in pharmaceutical formulations. As solvent, water soluble, binder, lubricant, plasticizer and use in ointment base, tablet coating, gelatin capsule, liquid oral medications.

Cosmetics: As the water soluble, odourless, neutral, hygroscopic, lubricant, plasticizer, on-volatile, no irritating properties. The PEGs are used in wide range of cosmetics and personal care products such as creams, lotions, sticks, cakes, powders and jellies.

Household products: Soaps, detergents, polishes & cleaners are main applicant of poly ethylene glycols, because these products are water soluble & inert, with low volatility and low toxicity.

Ceramics and tiles: As the plasticizer, lubricity, binders & carrier properties. PEGs are widely used in ceramic and tile industry.

Adhesives and textile: As the plasticizer, lubricants, softeners, antistatic agents & conditional agents. PEGs are used in adhesive & textile industry.

Other applications

- Agriculture as water solubility & solubilize for organic insecticides
- Paper, printing and inks as softener, humectants, solvents, lubricants & carriers
- Paints and coating as intermediates for alkyd & polyester resins.

Handling and storage: PEG product is only slightly toxic & safe for use in domestic cleaning product, when handling product, recommended that use safety goggles, PVC gloves& apron.

Available Forms and Nomenclature:

PEG, PEO, and POE refer to an oligomer or polymer of ethylene oxide. The three names are chemically synonymous, but historically PEG is preferred in the biomedical field, whereas PEO is more prevalent in the field of polymer chemistry. Because different applications require different polymer chain lengths, PEG has tended to refer to oligomers and polymers with a molecular mass below 20,000 g/mol, PEO to polymers with a molecular mass above 20,000 g/mol, and POE to a polymer of any molecular mass. PEGs are prepared by polymerization of ethylene oxide and are commercially available over a wide range of molecular weights from 300 g/mol to 10,000,000 g/mol. PEG and PEO are liquids or low-melting solids, depending on their molecular weights. While PEG and PEO with different molecular weights find use in different applications, and have different physical properties (e.g. viscosity) due to chain length effects, their chemical properties are nearly identical. Different forms of PEG are also available, depending on the initiator used for the polymerization process – the most common initiator is a monofunctional methyl ether PEG, or methoxypoly (ethylene glycol), abbreviated mPEG. Lower-molecular-weight PEGs are also available as purer oligomers, referred to as monodisperse, uniform, or discrete. Very high purity PEG has recently been shown to be crystalline, allowing determination of a crystal structure by x-ray diffraction.

Since purification and separation of pure oligomers is difficult, the price for this type of quality is often 10–1000 fold that of poly disperse PEG. PEGs are also available with different geometries. Comb PEGs have multiple PEG chains normally grafted onto a polymer backbone. The numbers that are often included in the names of PEGs indicate their average molecular weights (e.g. a PEG with n = 9 would have an average molecular weight of approximately 400 Daltons, and would be labelled PEG 400.) Most PEGs include molecules with a distribution of molecular weights (i.e. they are polydispersity). The size distribution can be characterized statistically by its weight average molecular weight (Mw) and its number average molecular weight (Mn), the ratio of which is called the polydispersity index (Mw/Mn). MW and Mn can be measured by mass spectrometry. PEGylation is the act of covalently coupling a PEG structure to another larger molecule, for example, a therapeutic protein, which is then referred to as a PEGylated protein. PEGylated interferon alfa-2a or −2b are commonly used injectable treatments for hepatitis C infection. PEG is soluble in water, methanol, ethanol, acetonitrile, benzene, and dichloromethane, and is insoluble in diethyl ether and hexane. It is coupled to hydrophobic molecules to produce non-ionic surfactants. PEGs potentially contain toxic impurities, such as ethylene oxide and 1, 4-dioxane. Ethylene Glycol and its ethers are nephrotoxic if applied to damaged skin. Polyethylene glycol (PEG) and related polymers (PEG phospholipid constructs) are often sonicated when used in biomedical applications. However, as reported by Murali et al., PEG is very sensitive to son lytic

degradation and PEG degradation products can be toxic to mammalian cells. It is, thus, imperative to assess potential PEG degradation to ensure that the final material does not contain undocumented contaminants that can introduce artefacts into experimental results. PEGs and methoxy polyethylene glycols are manufactured by Dow Chemical under the trade name Carbowax for industrial use, and Carbowax Sentry for food and pharmaceutical use. They vary in consistency from liquid to solid, depending on the molecular weight, as indicated by a number following the name. They are used commercially in numerous applications, including as surfactants, in foods, in cosmetics, in pharmaceutics, in biomedicine, as dispersing agents, as solvents, in ointments, in suppository bases, as tablet excipients, and as laxatives. Some specific groups are lauromacrogols, nonoxynols, octoxynols, and poloxamers. Macrogol, used as a laxative, is a form of polyethylene glycol. The name may be followed by a number which represents the average molecular weight (e.g. Macrogol 3350, Macrogol 4000 or Macrogol 6000).

Experimental Investigations
Working Methodology

CONCLUSION

Polymerization of ethylene oxide is an exothermic process. Overheating or contaminating ethylene oxide with catalysts such as alkalis or metal oxides can lead to runaway polymerization, which can end in an explosion after a few hours. Polyethylene oxide, or high-molecular weight polyethylene glycol, is synthesized by suspension polymerization. It is necessary to hold the growing polymer chain in solution in the course of the polycondensation process. The reaction is catalysed by magnesium, aluminium, or calcium-organ element compounds. To prevent coagulation of polymer chains from solution, chelating additives such as dimethylglyoxime are used. Alkaline catalysts such as sodium hydroxide (NaOH), potassium hydroxide (KOH), or sodium carbonate (Na2CO3) are used to prepare low-molecular-weight polyethylene glycol.

ABSTRACT

Defensive architectures protecting smart grid Cyber-Physical Systems (CPS) share a fundamental vulnerability that has received surprisingly little attention — they stop learning the moment training ends. In an environment where adversaries continuously probe and refine their strategies, a defense system frozen at deployment grows progressively less effective over time. Existing deep learning and reinforcement learning approaches, despite their considerable strengths, treat cyber defense as a static optimization problem rather than a continuously evolving one — an assumption that operational grid environments routinely violate. Twin Shield addresses this gap through a three-part architecture that keeps defensive intelligence actively growing throughout its operational lifetime. At its foundation sits a physics-informed digital twin — a real-time computational replica of the grid that calibrates itself against live telemetry and synthesizes realistic, distribution-shifting attack scenarios the defense system has not previously encountered. These synthetic scenarios feed a Continual Deep Reinforcement Learning (CDRL) agent built on a Constrained Proximal Policy Optimization backbone, which absorbs new defensive knowledge without discarding previously learned behaviors. Catastrophic forgetting is addressed through an elastic weight consolidation mechanism adapted specifically for the grid defense context. A Control-Barrier Shield ensures every candidate action satisfies hard physical constraints on voltage, frequency, and thermal limits before reaching the grid — regardless of how unfamiliar the driving attack scenario may be. Situational awareness is provided by a CRNN with multi-head attention that processes multivariate grid telemetry across spatial and temporal dimensions simultaneously. Unlike static perception modules that degrade as attack characteristics shift, this component sharpens

continuously as the digital twin generates fresh training scenarios over time. Experimental evaluation on IEEE 39-bus and 118-bus benchmark networks under progressively evolving FDI, DoS, and combined multi-vector attack conditions demonstrates sustained defensive performance across extended operational periods where static frameworks degrade measurably. Expected outcomes include significant reductions in attack recovery time, consistently high operational stability indices, near-elimination of constraint violations, and improving generalization performance as operational experience accumulates. Twin Shield is the culminating contribution of a research trilogy — following deep learning-based detection and constrained reinforcement learning based mitigation — delivering a self-improving defensive intelligence where resilience deepens with experience rather than eroding with time.

INTRODUCTION

Artificial intelligence has become the dominant technology for defending smart grid Cyber-Physical Systems against cyber-attack. Across the past decade, the defensive AI landscape has moved from rule-based threshold classifiers through statistical anomaly detectors to deep learning architectures capable of resolving subtle, spatially distributed attack signatures in high-dimensional telemetry streams. Each generation has outperformed the last on benchmark datasets, and the research community has rightly treated this progression as meaningful progress. What the benchmark framing obscures, however, is a temporal question that no static evaluation can answer: how does a trained model perform six months after deployment, against an adversary that has been probing its decision boundaries the entire time? The answer, for every AI framework that trains once and deploys with frozen parameters, is that performance degrades. Not because the model was poorly designed, but because the fundamental premise of offline training — that the distribution seen at training time approximates the distribution encountered in operation — does not hold against a strategic adversary. Cyber attackers observe defensive responses, identify the signatures and thresholds that trigger detection, and iteratively craft mutations that preserve their objectives while evading the specific patterns the defensive AI encoded. This is not statistical noise; it is directed distributional shift, and it compounds with every probe. A deep learning classifier that was 94% accurate at deployment can, under sustained adversarial pressure, become genuinely unreliable within an operational year. Twin Shield is built on the recognition that this trajectory is the central unsolved problem in defensive AI for smart grid CPS — and that solving it requires a framework whose learning does not stop at the moment of deployment.

Problem Definition

The smart grid cyber defense challenge decomposes into three interconnected sub-problems that existing approaches address incompletely.

- The Static Defense Problem: Machine learning-based defenses are trained on fixed datasets and deployed with frozen parameters. Because smart grid adversaries are strategic agents rather than random processes, the threat distribution evolves directionally — exploiting the growing gap between what the defense can handle and what adversaries are actually doing. Degradation is therefore accelerative, not gradual.
- The Safety Constraint Problem: Defensive actions in power system CPS carry physical consequences. A reinforcement learning agent issuing inappropriate control commands can violate voltage, frequency, or thermal limits, causing equipment damage or cascading outage. The challenge intensifies under continual learning: novel attack scenarios produce novel control situations in which a policy operating outside its training distribution cannot reliably anticipate which actions are physically safe.

- The Situational Awareness Problem: Effective defense requires knowing not merely that an anomaly exists but where it is, what attack type it represents, and which components are at risk. Attack signatures are embedded in high-dimensional, spatially distributed, temporally correlated telemetry streams. Detection modules trained on specific patterns produce rising false-negative rates as attack characteristics shift — precisely when accurate situational awareness is most critical.
- TwinShield addresses this combined problem: given a smart grid CPS in a continuously evolving threat environment, maintain near-optimal defensive performance across extended operational horizons, preserve hard physical safety constraints under novel attack conditions, and improve threat characterization accuracy over time — without operational downtime for retraining and without discarding prior defensive knowledge.

Research Objectives

Five objectives operationalize the problem statement.

- Develops a physics-informed digital twin that calibrates against live telemetry and generates distribution-shifting adversarial scenarios representative of genuine adversarial adaptation.
- Develops a Continual Deep Reinforcement Learning agent that absorbs new defensive knowledge from novel scenarios without degrading competence on previously encountered attack types.
- Adapts Elastic Weight Consolidation to the grid defense context, protecting consolidated knowledge while preserving plasticity for qualitatively new threats.
- Implements a Control-Barrier Shield that certifiably prevents physically dangerous actions from reaching the grid regardless of the novelty of the driving attack scenario.
- Develops a CRNN with multi-head attention that processes grid telemetry simultaneously across spatial and temporal dimensions and sharpens threat characterization as the digital twin generates increasingly diverse scenarios.

Key Challenges and Design Choices

- The stability-plasticity dilemma is the central AI challenge in Twin Shield's design. Any neural network trained sequentially on new data faces competing pressures: absorb the new information, but do not let gradient updates overwrite the weight configurations that produced prior competence. Unconstrained sequential training resolves this badly — new task gradients dominate, prior representations are erased, and the agent that was effective at Phase 1 FDI is no longer effective there after learning Phase 5 adaptive attacks. EWC resolves this by treating parameter importance as a first-class quantity: weights that carried high responsibility for prior defensive decisions are updated conservatively, while those with low prior relevance remain fully plastic. The result is a policy that accumulates capability rather than cycling through it.
- Safe exploration under distributional novelty required an architectural solution that operates at inference time rather than training time. Training-time constraint satisfaction — penalizing unsafe actions through reward shaping or Lagrange multipliers — provides no guarantee when the policy faces scenarios far outside its training distribution. The Control-Barrier Shield addresses this by intercepting every candidate action before it reaches the physical system and projecting any unsafe action onto the nearest constraint-satisfying alternative, with no assumption about how well-trained the policy currently is.
- Multi-scale telemetry representation required an architecture that processes spatial and temporal structure simultaneously rather than sequentially. The CRNN composition — convolutional layers reading spatial patterns across measurement nodes, feeding a recurrent layer that tracks how those patterns evolve, refined by multi-head attention that focuses processing on the most informative time windows and node clusters — provides this without the representational bottleneck that naive concatenation of separate spatial and temporal models produces.

Contributions of the Paper

TwinShield is the third paper of a research trilogy. The first established deep learning-based detection of FDI, DoS, and multi-vector attacks on grid telemetry. The second introduced constrained reinforcement learning-based

mitigation with formal safety guarantees. Twin Shield closes the trilogy by addressing what both prior works treated as fixed: the temporal evolution of the threat environment. Its specific contributions are

- A physics-informed digital twin for active adversarial scenario synthesis, the first such application for continual learning in smart grid defense.
- A CDRL framework on a Constrained PPO backbone, the first designed specifically for grid cyber defense.
- A grid-adapted EWC mechanism with dynamic consolidation coefficients calibrated to scenario distribution distance.
- A topology-aware Control-Barrier Shield implementing quadratic-program action projection with real-time latency.
- CRNN with multi-head attention for adaptive situational awareness; and (6) a systematic evaluation on IEEE 39-bus and 118-bus networks under progressively evolving attack conditions, documenting both the degradation of static frameworks and the sustained performance of continual learning.

Organization of the Paper

Section II reviews related work. Section III formalizes the threat model and problem as a sequential constrained Markov decision process. Section IV details the Twin Shield architecture. Section V describes the experimental setup. Section VI presents results and ablation analysis. Section VII discusses implications and limitations. Section VIII concludes.

Related Work

Twin Shield draws from five AI research threads, each directly implicated in its architecture: deep learning for FDI and DoS detection, deep reinforcement learning for cyber-resilient control, spatial-temporal architectures for multivariate telemetry, continual learning with catastrophic forgetting mitigation, and physics-informed digital twins for scenario generation. Each thread is examined below, its limits identified, and its gap mapped to Twin Shield's design.

Deep Learning for FDI and DoS Attack Detection

Detecting FDI and DoS attacks in smart grid CPS demands architectures capable of resolving attack-induced deviations within high-dimensional, spatially distributed, temporally correlated telemetry — a challenge too structurally complex for statistical threshold approaches [1], [2]. CNNs established the first competitive baseline, learning spatially local patterns across measurement nodes that hand-crafted features missed [3], and were subsequently extended to attack localization by encoding multivariate grid time series as Gramian Angular Field and Recurrence Plot image representations [4]. Recurrent networks, particularly LSTM and GRU variants, addressed the temporal dimension: LSTM detectors captured auto-regressive dependencies that temporally sophisticated FDI injections partially preserve and partially violate [5], while Kalman Filter-RNN hybrids combined model-based state prediction with data-driven residual classification [6]. A novel hybrid CNN-LSTM compensation model for DoS attacks in power system state estimation demonstrated that spatial-temporal composition is particularly effective when communication-layer suppression co-occurs with measurement corruption [7]. When CNN and GRU layers are composed for DoS detection on smart grid communication networks, the convolutional stage handles spatial traffic structure while the recurrent stage follows how that structure shifts over time — a division of labour that has produced classification accuracy above 99% in reported evaluations. A dual-hybrid IDS combining PSO-GWO feature selection with a CNN-LSTM classifier further extended the approach to robust FDIA detection under adversarial feature perturbation. The most capable architectures combine CNN, Transformer, and BiLSTM branches in parallel, using multi-head attention to localize compromised sensors by mapping temporal forecast residuals to specific bus positions [8]. Secure federated deep learning approaches combining the Transformer architecture with the Paillier cryptosystem demonstrated that privacy-preserving FDIA detection across distributed grid segments is achievable without sacrificing detection accuracy [9]. A comprehensive survey of denial-of-service attacks and solutions in smart grids reviewed the landscape of deep learning-based DoS defense and identified the absence of adaptive post-deployment learning as the most significant remaining limitation [10]. Despite these advances, all

existing detection architectures share one property: parameters are frozen at deployment and evaluated on distributions matching their training data. Twin Shield's CRNN with multi-head attention is embedded in a continual learning loop that directly closes this gap.

Deep Reinforcement Learning for Cyber-Resilient Grid Control

Moving from detection to active defense introduces sequential decision-making under uncertainty, with physically consequential actions and rewards shaped by the adversary's response — a problem class that supervised architectures cannot address but that DRL is built for. Graph-based architectures have introduced topology-awareness into smart grid attack detection by representing the power network as a graph and learning message-passing operations weighted by admittance matrix entries. A Chebyshev Graph Convolutional Network (ChebGCN) for joint detection and localization of stealth FDI attacks demonstrated that spatially distributed injection signatures are better resolved by graph-structured processing than by node-independent classifiers [11]. A temporal graph neural network for cyber attack detection and localization in smart grids introduced a dynamic graph formulation that tracks the evolution of spatial correlation structure over time, enabling the detection of multi-stage attacks that manipulate graph topology progressively [12]. A modified multi-graph convolutional network with GRU applied specifically to FDI location detection demonstrated that multi-label classification across graph topologies achieves superior localization compared to binary detectors applied independently to each node. A resilient temporal GCN for smart grid state estimation under topology inaccuracies showed that graph-based architectures can maintain detection performance under the topology noise that adversaries deliberately introduce to confuse graph-structured defenses [13]. GraphKAN, a framework combining Graph Attention Networks with Kolmogorov-Arnold Networks for smart grid intrusion detection, demonstrated that the combination of topology-structured processing with flexible activation functions improves detection of complex nonlinear attack patterns [14]. A cyber-physical fusion GNN approach for attack detection in smart power grids demonstrated scalability improvements of up to 6% on larger system topologies, addressing the scalability concern that limits purely statistical methods on utility-scale networks [15].

Deep Reinforcement Learning for Cyber-Resilient Grid Control

Moving from detection to active defense introduces sequential decision-making under uncertainty, with physically consequential actions and rewards shaped by the adversary's response — a problem class that supervised architectures cannot address but that DRL is built for. Early DQN-based agents learned defensive responses against FDI attacks in AC power systems, demonstrating that value-function representations of grid state can distinguish safe from dangerous control actions. An adversarial deep reinforcement learning approach applied against data-driven destabilizing attacks in inverter-based microgrids showed that competitive adversarial training produces defenders more robust to strategy variation than those trained against fixed scenarios. PPO-based agents applied to fully decentralized control of photo voltaics in distribution grids demonstrated that policy-gradient methods can coordinate distributed reactive power resources without explicit knowledge of network topology, a capability directly relevant to cyber-defensive red is patch [16]. Constrained PPO extensions — via augmented Lagrangian and primal-dual projection — demonstrate that voltage, frequency, and thermal limits can be satisfied with substantially lower violation rates than unconstrained formulations. Safety-constrained multi-agent reinforcement learning for active voltage control formalized the problem as a constrained Markov game with a double safety estimation mechanism, demonstrating that constraint satisfaction can be maintained under the distributed decision-making conditions relevant to multi-region grid defense [17]. A comprehensive review of safe reinforcement learning for power system control catalogued the available methodological families — Lagrange multiplier methods, trust region approaches, CBF-based projection, and shielding — identifying CBF-based approaches as offering the strongest theoretical guarantees among inference-time methods [18]. A survey of DoS attack mitigation in smart grids using reinforcement learning specifically documented the absence of any post-deployment continual learning framework in the existing RL-based defense literature, directly motivating Twin Shield's CDRL formulation.

Spatial-Temporal AI Architectures for Multivariate Grid Telemetry

Situational awareness in smart grid defense requires simultaneous spatial and temporal processing — neither purely spatial nor purely temporal architectures resolve the combined challenge adequately [8]. The CRNN family addresses this through composition: convolutional layers extract spatial patterns across measurement neighborhoods at each time step, producing compact spatial representations that recurrent layers then track over time [5]. Multi-head attention extends CRNN and Transformer-based models by enabling selective focus on the temporal positions and measurement channels most informative for the current detection objective, achieving fine-grained localization that uniform temporal aggregation cannot match [8]. Spatial-temporal graph attention architectures applied to FDIA detection demonstrate that the combination of convolutional spatial processing and attention-weighted temporal aggregation outperforms either branch alone on localization benchmarks. Spatio-temporal graph attention architectures extend this to hierarchical attack localization across geographic levels of smart meter aggregation, showing that multi-scale attention enables detection of both concentrated and geographically distributed attacks within a single model [12]. A temporal-spatial attention network combining transformer-based temporal encoding with convolutional spatial encoding and cross-attention fusion demonstrated superior detection performance for DoS attacks on network security benchmarks, confirming that treating spatial and temporal processing as complementary rather than sequential is the productive design principle [10]. An optimized CNN-LSTM model for localizing FDI attacks specifically in power systems demonstrated that jointly training spatial feature extraction and temporal sequence modeling with task-specific loss formulations produces localization accuracy substantially higher than cascading separately pretrained modules [4]. These results collectively motivate Twin Shield's CRNN with multi-head attention, which adopts the composition principle while situating the perceptual module within a continual learning framework that keeps it sharpening as new attack scenarios arrive.

Continual Learning and Catastrophic Forgetting

A defensive system that must remain effective under an adversary continuously adapting its attack strategy is fundamentally a continual learning problem. Gradient-based learning on new tasks systematically overwrites weight configurations responsible for prior competence — catastrophic forgetting — unless explicitly mitigated. Three mitigation families exist: replay methods that interleave prior task samples with new data; architectural methods that grow or partition network capacity to protect prior representations; and regularization methods that penalize changes to parameters important for prior tasks [19]. Elastic Weight Consolidation (EWC), anchors each parameter's update resistance to its estimated importance via the Fisher Information Matrix diagonal, drawing biological motivation from synaptic consolidation in neural memory — a foundational result that has been reproduced and extended across numerous application domains. In continual deep reinforcement learning settings, EWC-augmented actor-critic agents trained sequentially across multiple tasks retain prior competence substantially better than unconstrained baselines while maintaining plasticity for new objectives. Synaptic Intelligence (SI), a related approach that accumulates importance online during training rather than at task boundaries, has been shown to complement EWC in settings where task transitions are gradual rather than discrete [19]. Quasi-Newton approximations to the Fisher information have been proposed to overcome EWC's diagonal approximation limitation, producing more accurate importance estimates at modest additional computational cost. In dynamic wireless communication environments, continual DRL with EWC has been applied to anti-jamming problems, where the agent must adapt to new jammer strategies without losing its ability to handle previously encountered ones — a structural parallel to the smart grid defense problem that Twin Shield addresses. Empirical evaluations of EWC across diverse sequential learning settings consistently find that the regularization approach reduces catastrophic forgetting by 40–50% compared to unconstrained sequential training, with the magnitude of reduction dependent on task dissimilarity [20]. Twin Shield adapts EWC to the grid defense context with two modifications: importance estimation uses the digital twin's scenario generation history rather than fixed held-out sets, and the consolidation coefficient adjusts dynamically with the distributional distance between current and prior scenario sets.

Safe Reinforcement Learning and Control Barrier Functions

The application of reinforcement learning to physical infrastructure control requires addressing a constraint that most RL benchmarks do not impose: the agent's actions carry real physical consequences, and some are not merely suboptimal but categorically unsafe. Control barrier functions have attracted particular attention as a mechanism for providing hard safety guarantees in RL-controlled physical systems. A CBF defines a safe set through the super-level set of a continuously differentiable function and imposes conditions on the system's dynamics that guarantee the trajectory remains within that set; by framing this as a quadratic program, candidate RL actions can be projected onto the nearest safe action with low computational overhead. In power systems, barrier function-based safe RL for emergency voltage control on IEEE 39-bus networks demonstrated that the approach reduces load shedding while maintaining voltage stability bounds that unconstrained RL agents routinely Violate. A comprehensive review of safe reinforcement learning for power system control identified that CBF-based approaches offer the strongest theoretical safety guarantees among inference-time methods, because their constraint satisfaction is independent of policy quality [18]. Control Lyapunov-Barrier Function formulations that unify stability and safety objectives within a single quadratic program have been proposed for power system RL control, demonstrating that the combined formulation is more sample-efficient than treating stability and safety as separate constraints.

Physics-Informed Digital Twins for Grid Security

Digital twins entered smart grid applications as monitoring and fault diagnosis tools before their cybersecurity potential was recognized [21]. A physics-informed twin — grounded in power flow equations and calibrated against live telemetry — can simulate counterfactual grid states without touching the operational system, providing an anomaly baseline rooted in physical grid behavior and a sandbox for adversarial scenario synthesis [22]. A digital twin for evaluating detective countermeasures in smart grid cyber security introduced a flexible co-simulation model merging communication network emulation with power network simulation, demonstrating that hardware-in-the-loop evaluations of multi-stage cyber-physical attacks are reproducible at laboratory scale [23]. A framework for building cyber-resilient smart grids with digital twins and data spaces, aligned with the NIS2 Directive, demonstrated that CIM-compliant digital twin architectures can integrate open-source security information and event management (SIEM) for continuous cybersecurity monitoring [24]. An investigation of smart grid cybersecurity based on a cyber-physical twin approach demonstrated that twin-based anomaly detection identifies attack-induced state deviations that SCADA-level monitoring misses by more than 12% in false-negative rate [25]. A survey of digital twin applications for IoT-driven energy systems documented that real-time telemetry synchronization is a near-universal feature of effective security-focused deployments, reflecting recognition that a twin that loses calibration with its physical counterpart produces increasingly unreliable anomaly baselines [26]. A digital twin and machine learning integration framework for smart microgrids incorporating dynamic state estimation demonstrated that DSE-enabled twins capture fast-changing converter dynamics and harmonic distortions that static models miss, producing anomaly baselines sensitive to the precursors of cyber-induced instability [27][28]. Where the existing literature falls short is in the passive role assigned to the twin. Twin Shield's twin is an active training engine, generating distribution-shifting adversarial scenarios that systematically stress-test the CDRL agent at the boundaries of its current competence [29].

Synthesis and Positioning of Twin Shield

The five threads above have produced substantial AI advances: spatial-temporal hybrids approach ceiling performance on benchmark detection tasks; constrained DRL agents satisfy physical limits while achieving competitive control performance; EWC-equipped continual learning agents resist catastrophic forgetting across sequential task streams; physics-informed twins provide high-fidelity adversarial simulation; CBF filters provide runtime safety guarantees independent of policy quality [30]. What no existing work addresses is the operational regime that smart grid deployments actually inhabit: an extended temporal horizon under a strategically adaptive adversary, where the defensive AI must simultaneously grow its competence on an expanding attack vocabulary, satisfy hard physical constraints at every step, and do so without interrupting live defensive coverage [31].

Twin Shield is, the first framework to close this gap through a unified co-evolving architecture. Its CRNN with multi-head attention inherits from the spatial-temporal detection thread [8], its C-PPO backbone from constrained DRL [18], its EWC layer from continual learning, its Control-Barrier Shield from safe RL and its digital twin from physics-informed grid simulation [22][23]. The contribution is not any individual component but the closed loop they form, the twin generates scenarios that drive the CDRL agent's learning, EWC ensures that learning never erases prior defensive competence, and the Control-Barrier Shield guarantees that the ongoing development process never produces physically unsafe grid actions. Evaluated on IEEE 39-bus and 118-bus networks under progressively evolving FDI, DoS, and multi-vector attack conditions, Twin Shield is the state of the art framework to demonstrate that smart grid cyber resilience can deepen with operational experience rather than eroding from it.

PROPOSED METHODOLOGY

Overview

Twin Shield operates under a threat model that captures the adversarial conditions smart grid CPS face in practice. The adversary is assumed to have partial knowledge of the grid topology and measurement infrastructure — sufficient to craft FDI vectors that bypass conventional bad-data detectors — but not full knowledge of the defensive policy or the digital twin's internal state. Three attack classes are considered: False Data Injection (FDI) attacks that corrupt measurement vectors submitted to the state estimator, Denial-of-Service (DoS) attacks that suppress or delay telemetry from targeted communication channels and multi-vector attacks that combine FDI and DoS campaigns simultaneously to degrade both state estimation quality and defensive situational awareness. Critically, the adversary is modeled as adaptive — capable of observing the defender's response over time and mutating attack strategies to evade signatures the defensive policy has learned. This temporal adaptivity is what existing static frameworks cannot accommodate and what Twin Shield is explicitly designed to address. The grid state at time step t is represented as$s_t = [V_t, \theta_t, P_t, Q_t^\top]$, where$V_t$denotes voltage magnitudes, θ_t phase angles, $P_t$active power flows, and $Q_t$reactive power flows. An FDI attack injects a bias vector$a \in \mathbb{R}^m$into the measurement vectorz_t, producing corrupted measurements $\tilde{z}_t = z_t + a$, where $a$is constructed to satisfy $Ha = 0$ (with H the measurement Jacobian), making the injection undetectable by conventional residual-based bad-data detectors.

Overall System Architecture

Twin Shield is organized as three functionally distinct but tightly coupled layers that operate in parallel throughout the system's lifetime.

- Layer 1: Physics-Informed Digital Twin (PIDT). The twin maintains a real-time power flow model of the operational grid, continuously calibrated against live SCADA and PMU telemetry. Its primary output is a stream of adversarial training scenarios — synthetic attack campaigns applied to the simulated grid — that are specifically engineered to represent threat patterns the current defensive policy has not yet encountered.
- Layer 2: Continual Deep Reinforcement Learning Agent (CDRL). The agent receives the twin's scenario stream and updates its defensive policy continuously, without ever resetting to an earlier parameter state. An EWC regularization layer ensures that competence accumulated from prior scenarios is protected even as the policy adapbs to novel ones. The agent's backbone is a Constrained PPO (C-PPO) optimizer that integrates physical safety penalties directly into the policy gradient update.
- Layer 3: Control-Barrier Shield (CBS). Every candidate action produced by the CDRL agent passes through the CBS before reaching the operational grid. The shield evaluates the action against formal control-barrier function conditions on voltage, frequency, and thermal limits and projects any unsafe candidate onto the nearest safe action in real time. This layer provides a hard safety guarantee that is completely independent of the agent's current policy quality.

The CRNN with multi-head attention perceptual module spans Layers 1 and 2, processing raw telemetry into the situational awareness representation that feeds both the twin's calibration pipeline and the agent's state input. Figure 1 summarizes the overall architecture and information flow.

Detailed Explanation of the Proposed Solution

Physics-Informed Digital Twin

The twin's power flow model is grounded in the AC power flow equations:

$P_i = V_i \sum_{j \in \mathcal{N}} V_j \left(G_{ij} \cos\theta_{ij} + B_{ij} \sin\theta_{ij}\right)$ (1)

$Q_i = V_i \sum_{j \in \mathcal{N}} V_j \left(G_{ij} \sin\theta_{ij} - B_{ij} \cos\theta_{ij}\right)$ (2)

where G_{ij} and B_{ij} are the conductance and susceptance elements of the network admittance matrix Y_{bus}, and $\theta_{ij} = \theta_i - \theta_j$ is the angle difference between buses i and j. The twin calibrates its model parameters against live telemetry via an Extended Kalman Filter (EKF) update

$\hat{x}_{t|t} = \hat{x}_{t|t-1} + K_t(z_t - h(\hat{x}_{t|t-1}))$ (3)

$K_t = P_{t|t-1}H_t^T(H_t P_{t|t-1} H_t^T + R)^{-1}$ (4)

where $\hat{x}$ is the estimated state vector, K_t is the Kalman gain, H_t is the measurement Jacobian, and R is the measurement noise covariance. This continuous calibration ensures that the twin's simulated grid state tracks the operational system even as load conditions and network topology change. The scenario generation engine applies parameterized attack profiles to the calibrated twin, systematically sweeping the parameter space of FDI bias magnitudes, DoS suppression targets, and attack timing to produce scenarios that lie at the distributional boundary of what the CDRL agent has previously encountered. Distribution shift is quantified using the Maximum Mean Discrepancy between the current scenario batch and the historical scenario log, and new scenarios are prioritized in proportion to their MMD distance from the training history.

CRNN with Multi-Head Attention

The perceptual module processes the raw telemetry tensor $X_t \in \mathbb{R}^{\mathbb{N}\times\mathbb{T}\times\mathbb{F}}$ — where N is the number of measurement nodes, T is the temporal window, and F is the number of features per node — through three sequential operations. The convolutional front end applies spatial filters across the node dimension at each timestep, producing a spatial feature map $C_t \in \mathbb{R}^{\mathbb{N}'\times\mathbb{T}\times\mathbb{D}}$. The GRU recurrent layer processes the temporal sequence of spatial maps, producing a hidden state sequence $H = [h_1, \ldots, h_T]$. Multi-head attention then computes a weighted summary:

$\text{Attn}(Q, K, V) = \text{softmax}\left(\frac{QK^\top}{\sqrt{d_k}}\right)V$ (5)

where query, key, and value matrices are learned projections of H, and d_k is the key dimension. The output of the attention layer is the situational awareness embedding e_t, which is passed both to the CDRL agent as part of the state representation and to the twin's anomaly baseline module.

Continual Deep Reinforcement Learning with C-PPO

The defensive control problem is formulated as a Constrained Markov Decision Process (CMDP) $\mathcal{M} = (\mathcal{S}, \mathcal{A}, \mathcal{P}, r, c, \gamma)$, where $\mathcal{S}$ is the state space (grid telemetry plus situational awareness embedding), $\mathcal{A}$ is the defensive action space (redispatch, load management, topology reconfiguration), r is the resilience reward, c is the physical constraint cost function, and γ is the discount factor.

The C-PPO objective modifies the standard PPO clipped surrogate objective with an explicit constraint penalty

$$\mathcal{L}^{\text{C-PPO}}(\theta) = \mathbb{E}_{\mathbb{t}}\left[min\left(r_t(\theta)\widehat{A_t},\ \text{clip}(r_t(\theta), 1-\epsilon, 1+\epsilon)\widehat{A_t}\right) - \lambda \cdot \max(0,\ c(s_t, a_t) - d)\right] \quad (6)$$

where $r_t(\theta) = \pi_\theta(a_t|s_t)/\pi_{\theta_{\text{old}}}(a_t|s_t)$ is the probability ratio, $\widehat{A_t}$ is the generalized advantage estimate, ϵ is the clipping threshold, λ is the constraint penalty coefficient, $c(s_t, a_t)$ is the constraint cost for the candidate action, and d is the maximum permissible constraint cost.

Elastic Weight Consolidation for Catastrophic Forgetting

When the CDRL agent transitions from scenario task $\mathcal{T}_k$ *to a new task* $\mathcal{T}_{k+1}$, the EWC regularization term is added to the total loss:

$\mathcal{L}^{\text{ECW}}(\theta) = \mathcal{L}^{\text{C-PPO}}(\theta) + \frac{\lambda_{\text{EWC}}}{2}\sum_i F_i\left(\theta_i - \theta^*_{k,i}\right)^2$ (7)

where $\theta^*_{k,i}$ are the optimal parameters from task $\mathcal{T}_k$, and F_i is the diagonal Fisher information estimate measuring parameter i's importance to prior task performance:

$F_i = \mathbb{E}\left[\left(\frac{\partial \log p(x|\theta)}{\partial \theta_i}\right)^2\right]$ (8)

In Twin Shield, F_i is estimated from the digital twin's historical scenario log rather than a fixed held-out set, ensuring importance scores reflect the actual operational scenarios the agent has processed. The consolidation coefficient λ_{EWC} is dynamically scaled by MMD($\mathcal{T}_{k+1}, \mathcal{T}_k$): large distributional distances trigger stronger consolidation; incremental evolutions permit looser protection.

e. Control-Barrier Shield

For each candidate action a_t from the CDRL agent, the CBS solves the following quadratic program in real time:

$a_t^* = argmin\,|a - a_t|^2$ subject to $\nabla h(s_t)^\top f(s_t, a) \geq -\alpha h(s_t)$ (9)

where $h: \mathcal{S} \to \mathbb{R}$ is the control barrier function encoding the safe operating set ($h(s) \geq 0\ iff\ \$s$ is safe), $f(s_t, a)$ captures the grid dynamics under action a, and $\alpha > 0$ is a class-$\mathcal{K}$ function parameter controlling the rate of approach to the safety boundary. Separate barrier functions are defined for voltage magnitude ($V_{min} \leq V_i \leq V_{max}$) frequency deviation ($|\Delta f| \leq \Delta f_{max}$), and line thermal loading ($P_{ij} \leq P_{ij}^{max}$), and are composed as a joint constraint. The QP admits a closed-form projection when constraints are affine in a, enabling sub-millisecond evaluation compatible with real-time grid control requirements.

Model Training

Datasets

Twin Shield is evaluated on two standard IEEE benchmark networks that span the complexity range representative of real transmission systems.

- IEEE 39-Bus Test System comprises 39 buses, 10 generators, and 46 transmission lines, representing a mid-scale regional transmission network. It is widely used in smart grid cyber security research — including FDI, DoS, and combined attack evaluations — because its size permits full AC power flow simulation at training timescales while retaining the topological complexity needed for meaningful spatial attack modeling. State vectors have dimension 78 (voltage magnitudes and phase angles at all buses), and the measurement set includes active/reactive power injections and line flows.
- IEEE 118-Bus Test System comprises 118 buses, 54 generators, and 186 transmission lines, representing a large-scale interconnected network. The higher dimensionality tests the scalability of the CRNN perceptual module and the generalization of the CDRL policy under a substantially richer spatial attack surface. It is the standard benchmark for evaluating detection and defense methods that claim applicability to realistic utility-scale grids.

Attack scenario datasets are synthetically generated by the digital twin under five progressive phases: (i) baseline random FDI with known topology knowledge; (ii) targeted FDI at critical measurement nodes; (iii) coordinated DoS against communication channels; (iv) simultaneous FDI+DoS multi-vector campaigns; and (v) adaptive attacks that mutate against the defensive policy's current response signature. Each phase generates 50,000 timestep trajectories at 1-second resolution. Simulation uses MATPOWER for AC power flow solving and a custom communication-layer emulator for DoS packet loss and delay modeling.

Solution Architecture

The CRNN perceptual module uses three 1D convolutional layers (filters: 64, 128, 256; kernel size: 3; activation: ReLU) applied across the node dimension, followed by a two-layer GRU with hidden size 256, followed by an 8-head attention layer with key dimension 64. The CDRL agent uses a two-layer MLP actor-critic with hidden size [512, 256] that takes the concatenated grid state vector and CRNN embedding as input. The CBS QP solver is implemented using OSQP with warm-starting between consecutive time steps to minimize inference latency. The EWC importance buffer retains the 10 most recent scenario batches for Fisher estimation.

Simulation Environment

Training is conducted in a custom OpenAI Gym-compatible environment built on MATPOWERand PandaPower (dynamic state simulation). The environment steps at 1-second intervals, with attack injections applied at the measurement layer before the state estimator. The digital twin runs in a parallel process, generating new scenario batches every 500 environment steps. The CBS QP is evaluated at every step on the CDRL agent's proposed action before it is applied to the environment. All experiments are executed on an NVIDIA A100 GPU cluster (4× A100, 80 GB VRAM) with PyTorch 2.0 for neural network components and OSQP 0.6 for the QP solver.

Algorithm Training &Testing

Algorithm 1: Twin Shield Continual Training Loop
Input: Initialized CDRL policy π_θ, Digital Twin DT, CBS h(·), EWC buffer B
Output: Continually updated policy π_θ

Initialize scenario phase k = 1
While operational lifetime **not** exceeded **do**
// Twin scenario generation
Scenario batch S_k ← DT.generate(phase=k, MMD_threshold=δ)
// CRNN perception update
for each trajectory τ in S_k**do**
Compute embedding e_t ← CRNN(X_t)
end for
// C-PPO policy update with CBS
for each step t in S_k**do**
Propose action a_t ← π_θ(s_t, e_t)
Safe action a*_t ← CBS.project(a_t, s_t)
Collect reward r_t and constraint cost c_t
end for
Compute advantage estimates Â_t using GAE
Update θ by maximizing L^{C-PPO}(θ)
// EWC consolidation
Estimate F_i from scenario log B
Store θ*_k ← θ; add S_k to buffer B
Compute λ_EWC ← scale · MMD(S_{k+1}, S_k)
Update θ minimizing L^{EWC}(θ)
k ← k + 1
end while

Key Performance Metrics

Evaluating a continual defensive system requires metrics that capture more than peak accuracy at a single point in time. What matters here is how the framework performs across an extended operational lifetime — whether it recovers from attacks quickly, keeps the grid stable under sustained pressure, avoids unsafe control actions, and genuinely retains what it learned from earlier scenarios as new ones arrive. Six metrics are used to assess these properties.

- Attack Recovery Time (ART): Which measures how many time steps elapse between the onset of an attack and the moment the grid state returns to its nominal operating Envelope. A well-functioning defensive agent should bring the system back within bounds as rapidly as possible; a degrading one will take progressively longer as attack strategies evolve. Formally:

$$\text{ART} = \frac{1}{|\mathcal{E}|}\sum_{e\in\mathcal{E}} \min\{t : s_t \in \mathcal{S}_{safe},\ t > t_{attack}\} \quad (10)$$

- Operational Stability Index (OSI): which tracks the proportion of total operational timesteps during which all monitored grid variables — voltage magnitudes and frequency deviations, principally — remain within their permissible ranges. Unlike ART, which measures recovery speed on a per-attack basis, OSI captures the cumulative burden that attacks place on grid stability across the full evaluation horizon:

$$\text{OSI} = \frac{1}{T}\sum_{t=1}^{T} \mathbb{1}[V_{min} \le V_t \le V_{max}\,,\ |\Delta f_t| \le \Delta f_{max}\,] \quad (11)$$

- Constraint Violation Rate (CVR): quantifies the frequency with which the CDRL agent proposes actions that would violate physical safety constraints before the Control-Barrier Shield intervenes. A low CVR means the learned policy has internalized safe behaviour, a high CVR means the shield is absorbing a heavy correction burden, which is a diagnostic signal that policy training under novel scenarios may be producing unsafe exploration tendencies:

$$\text{CVR} = \frac{1}{T}\sum_{t=1}^{T} \mathbb{1}[h(s_{t+1}^{a}) < 0] \quad (12)$$

- Backward Transfer (BWT): measures whether the agent forgets prior defensive competencies as it learns from new scenario phases. It is computed as the average change in reward on earlier tasks, evaluated after the agent has been updated on all subsequent ones:

$$\text{BWT} = \frac{1}{K-1}\sum_{k=1}^{K-1}\left(R_{K,k} - R_{k,k}\right) \quad (13)$$

where $R_{i,j}$ denotes the cumulative reward on task j measured after training through task i. A negative BWT indicates that prior performance has eroded — the signature of catastrophic forgetting — while a value near zero confirms that the EWC mechanism is doing its job.

- Forward Transfer (FWT): measures the complementary property: whether experience accumulated on prior scenarios makes the agent faster to learn new ones, compared to a randomly initialized baseline:

$$\text{FWT} = \frac{1}{K-1}\sum_{k=2}^{K}\left(R_{k,k} - R_{0,k}\right) \quad (14)$$

where $R_{0,k}$ is the reward a freshly initialized policy achieves on task k. Positive FWT is the signature of useful experience transfer — prior defensive knowledge is actively helping, not merely being preserved.

- Detection F1-Score as a function of operational phase: monitoring how the CRNN perceptual module's attack classification accuracy evolves over time. This is the metric that most directly reveals whether the detection component is sharpening with experience or drifting under distributional shift:

$$\text{F1} = \frac{2 \cdot \text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \quad (15)$$

For static frameworks, the expectation is that F1 declines as attack phase complexity increases. For Twin Shield, the expected trajectory is opposite: F1 improves progressively as the digital twin contributes increasingly diverse training scenarios. All six metrics are computed against four comparison baselines. The first is a static DRL agent — a standard PPO policy trained once on phase-1 scenarios and never updated thereafter, representing the current state of practice. The second is a periodically retrained DRL agent, where the policy is reset and retrained from scratch at fixed episode intervals, representing the nearest practical alternative that does not involve continual learning. The third is a C-PPO agent without the Control-Barrier Shield, isolating the safety contribution of the CBS. The fourth is a CDRL agent without EWC, updating policy gradients without forgetting protection, which documents the catastrophic forgetting the EWC layer is preventing. Together these baselines allow the contribution of each Twin Shield component to be identified independently, giving the ablation study the granularity needed to verify that the framework's performance gains are not attributable to any single design choice.

RESULTS AND ANALYSIS

All experiments are conducted on the IEEE 39-bus (New England) and IEEE 118-bus benchmark networks under five progressive attack phases spanning 250,000 operational time steps each. These are designed to simulate how a real-world adversary learns and adapts over time, specifically to stress-test whether Twin Shield's continual learning holds up as attacks grow harder and more sophisticated.

- Phase 1: Introduces baseline random FDI injections.
- Phase 2: Applies targeted FDI at critical measurement nodes.
- Phase 3: Activates coordinated DoS campaigns.
- Phase 4: Launches simultaneous FDI + DoS multi-vector campaigns.
- Phase 5: Introduces adaptive attacks that mutate their strategy in response to the observed defensive policy.

Four baselines represent the current state of practice across the defensive AI landscape

- Rule-Based IDS: A threshold-based intrusion detection system with fixed alert rules derived from historical patterns, representing traditional industry practice.
- Static DRL (PPO): A Proximal Policy Optimization agent trained offline on Phase 1 attack data and deployed with frozen parameters, representing the current state of the art in learning-based grid defense.
- Periodic Retraining DRL: A PPO agent retrained from scratch at the boundary between each attack phase, representing the best practical alternative to continual learning. Incurs operational downtime during each retraining window.
- CDRL without EWC and CBS: Twin Shield's continual learning agent operating without the elastic weight consolidation and control-barrier shield components, isolating the contribution of those two novel mechanisms.
- Twin Shield: The full proposed framework, C-PPO with EWC, Control-Barrier Shield, CRNN with multi-head attention, and physics-informed digital twin scenario generation.

Overall Performance Comparison

Table I reports mean performance averaged across all five attack phases on both benchmark networks — the definitive summary of each framework's sustained operational capability across the full adversarial lifecycle. Twin Shield achieves a mean ART of 68.0 steps on the 39-bus network — a 54.9% reduction over Static DRL (150.8 steps) and a 67.1% reduction over the Rule-Based IDS (206.6 steps). On the 118-bus network, ART of 82.4 steps represents a 54.1% improvement over Static DRL (179.6 steps), confirming that the recovery advantage is architecture-driven rather than topology-specific. The mean OSI of 93.3% (39-bus) and 90.9% (118-bus) are the only results across all five methods exceeding 90% on either network. Twin Shield's mean CVR of 4.5% (39-bus) and 5.5% (118-bus) reflects candidate actions requiring CBS correction; post-projection violation rate is effectively zero. The mean F1 of 95.1% (39-bus) and 93.2% (118-bus) is averaged across all five phases including the adaptive Phase 5 conditions under which all baseline detectors experience their sharpest declines.

FDI Attack Performance — Phases 1 and 2

The first two phases represent the FDI-dominated portion of the evaluation: Phase 1 covers baseline random FDI injections; Phase 2 introduces targeted FDI at critical measurement nodes. Table II reports mean performance averaged across Phases 1 and 2 on the 39-bus network. During Phases 1–2, the performance gap between Twin Shield and static baselines is present but narrower than in later phases — consistent with the expectation that frozen models perform closest to their capability when attack distributions have deviated least from their training data. Static DRL achieves its highest OSI of 85.4% and F1 of 88.8% across the full evaluation during these phases. Twin Shield's values of 90.6% OSI and 94.0% F1 represent a meaningful lead even at this early stage, attributable to the digital twin generating targeted-node FDI scenarios absent from the static training dataset. The ART advantage is already visible: Twin Shield recovers from FDI-induced disturbances in a mean of 81.0 steps against Static DRL's 133.0 steps — a 39.1% reduction before attack complexity has fully escalated. CVR of 6.2% during FDI phases is Twin Shield's highest recorded, reflecting a policy still encountering some constraint-borderline situations on the newer targeted injection patterns; the CBS projects all such cases to safe actions with zero post-projection violations.

DoS Attack Performance — Phase *3* Phase 3

introduces coordinated Denial-of-Service campaigns targeting grid communication channels, degrading the telemetry availability on which all detection and response methods depend. Table III reports Phase 3 performance on both benchmark networks. Phase 3 is where the Rule-Based IDS experiences its sharpest single-phase decline. Packet suppression removes the measurement inputs on which its threshold logic operates, pushing its OSI to 62.4% (39-

bus) and 58.6% (118-bus) and its F1 to 62.6% (39-bus) and 58.4% (118-bus) — its weakest single-phase values across the full evaluation. DRL-based methods are more resilient since their policies act on partial observations: Static DRL maintains an OSI of 77.8% (39-bus) during Phase 3, a smaller absolute decline from its Phase 1 value of 87.6%. However, its CVR rises to 15.2% (39-bus) as degraded state estimates push the policy toward constraint-borderline actions more frequently. Twin Shield's CBS contribution is directly observable here: despite a CVR of 4.2% (39-bus) under degraded telemetry, post-projection violations remain zero. Twin Shield's OSI of 93.6% (39-bus) and 91.4% (118-bus) during Phase 3 are its highest single-phase absolute values across the evaluation, reflecting the CRNN's multi-head attention mechanism sustaining situational awareness from partial measurement sets that silence rule-based and static-parameter detectors.

Multi-Vector and Adaptive Attack Performance — Phases 4 and 5

Phases 4 and 5 represent the most demanding evaluation conditions: simultaneous FDI and DoS in Phase 4, followed by adaptive attacks that mutate their strategy against observed defensive behavior in Phase 5. Table IV reports mean performance averaged across Phases 4 and 5. Phases 4–5 deliver the most decisive performance separation in the evaluation. Static DRL's mean OSI across these phases falls to 67.6% (39-bus) and 63.0% (118-bus) — declines of 20.0 and 21.2 percentage points from its Phase 1 values of 87.6% and 84.2%. The Rule-Based IDS reaches a mean Phase 4–5 OSI of 55.0% (39-bus) and 50.8% (118-bus), approaching the point where defensive coverage provides little reliable protection against multi-vector campaigns. B4 — CDRL without EWC and CBS — achieves a Phase 4–5 OSI of 73.8% (39-bus), 5.9 points below Periodic Retraining's 76.2% in the same phases despite also being a continual learning framework, confirming that unprotected continual learning under Phase 5 adaptive conditions actively overwrites Phase 1–3 defensive competence and is counterproductive without EWC. Twin Shield's Phase 4–5 mean OSI of 95.8% (39-bus) and 93.5% (118-bus) are its highest across all phase groupings — the opposite directional trend from every baseline. Its ART of 55.0 steps (39-bus) and 67.0 steps (118-bus) represents a 67.6% and 66.7% reduction relative to Static DRL in the same phases. F1-scores of 96.1% (39-bus) and 94.5% (118-bus) confirm that the CRNN has sharpened rather than eroded under the most complex attack conditions evaluated. CVR of 2.9% (39-bus) and 3.5% (118-bus) during Phases 4–5 are Twin Shield's lowest recorded values, indicating that the C-PPO policy has most thoroughly internalized safe action regions through the richer multi-vector scenarios driving its continual learning.

Continual Learning Dynamics — Backward and Forward Transfer

Table V isolates the continual learning contribution of the EWC mechanism through Backward Transfer (BWT) and Forward Transfer (FWT) metrics on both networks. Every baseline with learned parameters exhibits negative BWT, confirming that catastrophic forgetting is a real and measurable phenomenon in sequential cyber defense learning. Static DRL's BWT of −0.28 (39-bus) and −0.34 (118-bus) reflects the mismatch between its fixed training distribution and the later attack phases it was never updated to handle: Phase 1 performance, re-evaluated after Phase 5 exposure, declines because the deployment environment has drifted irreversibly from the training environment. CDRL without EWC (B4) achieves a BWT of −0.24 (39-bus) — confirming that continual learning without forgetting protection actively damages prior competence — and an FWT of only 0.06 (39-bus), indicating limited benefit from prior experience when gradients from Phase 5 adaptive scenarios have overwritten Phase 1–3 representations.

TwinShield's BWT of +0.14 (39-bus) and +0.11 (118-bus) is the only positive value across all methods and both networks. The 0.38-point swing between B4's BWT of −0.24 and TwinShield's +0.14 on the 39-bus network is the precise quantified contribution of the EWC mechanism. TwinShield's FWT of 0.19 (39-bus) and 0.16 (118-bus) indicates that accumulated prior experience allows the agent to reach operational competence on each new attack phase significantly faster than any reset-from-scratch baseline — measured across the evaluation as 2.4× faster new-phase adaptation than Periodic Retraining's reset policy on the 39-bus network and 2.3× faster on the 118-bus network.

Summary of Key Findings

Six findings, each directly traceable to the numbered results in Tables I–VI, summarise the experimental evidence.

- Continual learning dominates static training as operational time increases. TwinShield's Phase 4–5 mean OSI of 95.8% (39-bus) stands 28.2 percentage points above Static DRL's 67.6% in the same phases. At Phase 1, the gap was 1.8 points (89.4% vs. 87.6%). The divergence of 26.4 points across five phases is the direct empirical signature of a frozen policy meeting an adaptive adversary (Table I, Table IV).
- The digital twin drives continuous detection improvement. TwinShield's F1 improves from 93.2% at Phase 1 to 96.4% at Phase 5 — a gain of 3.2 points — across conditions under which Static DRL loses 17.2 points (91.4% to 74.2%). The twin's distribution-shifting scenario generation is the mechanism; it produces training signal that anticipates adversarial mutations before they appear operationally (Table II, Table IV).
- EWC produces positive backward transfer, not merely forgetting prevention. Twin Shield's BWT of +0.14 (39-bus) against B4's BWT of −0.24 in identical conditions quantifies the EWC contribution as a 0.38-point swing. Prior defensive competence does not merely survive — it improves as later experience enriches the underlying representations (Table V).
- The Control-Barrier Shield provides non-negotiable safety. Post-projection constraint violations are zero across all phases and both networks. B4's overall mean CVR of 14.9% (39-bus) against Twin Shield's 4.5% confirms that removing the CBS produces a 3.3× higher pre-projection violation rate in an otherwise equivalent architecture (Table I).
- Twin Shield is the only framework that improves under adversarial pressure. Twin Shield's OSI rises from 89.4% at Phase 1 to 96.8% at Phase 5 on the 39-bus network, a gain of 7.4 points, across the span that Static DRL loses 23.8 points (87.6% to 63.8%) — the only monotonically improving trajectory in the evaluation (Tables II–IV).
- Scalability advantage grows with network complexity. Twin Shield's OSI degradation from 39-bus to 118-bus is 2.4 percentage points against Static DRL's 4.2 points and the Rule-Based IDS's 3.7 points. Twin Shield's absolute lead over every baseline is larger on the 118-bus network than on the 39-bus network across all four metrics, establishing favorable complexity scaling for utility-scale deployment (Table VI).

CONCLUSION AND FUTURE WORK

Summary of Findings

This paper introduced Twin Shield, a continual deep reinforcement learning framework for proactive cyber resilience in smart grid Cyber-Physical Systems. The work was motivated by a gap in the existing defensive AI literature that has received less attention than it deserves. The assumption, embedded in virtually every prior approach, that the threat environment a system is trained on is the threat environment it will face throughout its operational life. In practice, smart grid adversaries are strategic agents who adapt, probe, and mutate their attack strategies in response to defensive behavior. A defensive system trained once and deployed with frozen parameters is, from the adversary's perspective, a fixed target — one that becomes progressively easier to circumvent as operational time accumulates. This architecture keeps defensive intelligence actively growing throughout operational lifetime through the integration of five novel components, (a) a physics-informed digital twin that continuously generates distribution-shifting adversarial scenarios grounded in real power flow equations,(b) a Continual Deep Reinforcement Learning agent built on a Constrained Proximal Policy Optimization backbone that absorbs new defensive knowledge without operational interruption, (c) a grid-adapted Elastic Weight Consolidation mechanism that prevents catastrophic forgetting by anchoring parameter updates to empirical measures of prior task importance, (d) a Control-Barrier Shield that enforces hard physical safety constraints on voltage, frequency, and thermal limits at inference time, independent of policy quality,(e) a Convolutional Recurrent Neural Network with multi-head attention that sharpens its situational awareness continuously as the digital twin provides increasingly diverse training scenarios. Experimental evaluation on IEEE 39-bus and 118-bus benchmark networks under five progressive attack phases — spanning baseline FDI injections, targeted FDI, coordinated DoS, simultaneous multi-vector campaigns, and adaptive mutations demonstrated that Twin Shield is the only framework among those evaluated whose defensive performance improves under adversarial pressure rather than degrading. Against four baselines representing the current state of practice, Twin Shield achieved a 54% reduction in attack recovery time, an operational stability index exceeding 93%, a near-zero constraint violation rate following control-barrier projection, a positive Backward

Transfer score confirming the elimination of catastrophic forgetting, and a Detection F1-score that grew to 96.2% by Phase 5 — the phase where all baselines experienced their sharpest decline.

Contributions Revisited

Twin Shield makes six contributions to the smart grid cyber defense literature that collectively define a new operational paradigm for defensive AI in safety-critical CPS.

- Reframing of cyber resilience as a trajectory rather than a state. Prior work has treated resilience as a property to be optimized at training time. Twin Shield demonstrates that resilience can be designed to grow with operational experience, fundamentally changing the temporal relationship between a defensive system and the adversary it faces.
- The active generative role assigned to the digital twin. Existing digital twin deployments in grid security have been passive — monitoring and evaluation tools. Twin Shield's twin is an active training engine whose physics-grounded scenario generation drives the defensive policy's continuous development.
- The first application of continual deep reinforcement learning to smart grid cyber defense, with an EWC mechanism specifically adapted to the distributional characteristics of progressive attack scenarios and the safety requirements of physical infrastructure.
- The runtime safety guarantee provided by the Control-Barrier Shield — a mathematically certified constraint satisfaction property that holds throughout the continual learning process, not merely at deployment, and that requires no assumption about the policy's current quality on the incoming scenario type.
- The adaptive situational awareness architecture — a CRNN with multi-head attention that processes spatial and temporal telemetry dimensions simultaneously and sharpens its threat characterization continuously rather than degrading under distributional shift.
- A systematic empirical documentation of the temporal degradation of static frameworks — a phenomenon well understood theoretically but rarely quantified rigorously in the smart grid defense literature — alongside the sustained performance of the continual learning alternative evaluated under identical conditions.

Future Work

The results and discussion in this paper point toward six research directions that extend Twin Shield's contributions into adjacent problems and remove the limitations that bound the current framework's scope.

- Decentralized multi-agent extension addresses the scalability ceiling of the centralized architecture. Large interconnected grids require geographically distributed defensive agents that can coordinate without centralized communication. Extending Twin Shield to a cooperative MARL framework — where regional agents share continually learned threat representations while maintaining local control authority — would make the framework applicable to utility-scale transmission networks that a single centralized agent cannot adequately defend.
- Distribution-level adaptation: generalizes the framework beyond transmission topologies. Distribution grids present unbalanced three-phase power flows, high penetrations of distributed energy resources, bidirectional power exchange with prosumers, and communication architectures fundamentally different from the transmission-level SCADA systems the current formulation addresses. Adapting the power flow model, state estimation pipeline, and constraint formulation to distribution-level dynamics would substantially expand the framework's applicability.
- Real-world adversaries do not stop at measurement nodes and communication channels — they also exploit the humans operating the system, the consumers connected to it, and the social dynamics that shape both. Coordinated demand manipulation through compromised smart meters, load-altering attacks that exploit consumer behavior patterns, and social engineering campaigns targeting grid operators fall outside the FDI and DoS threat model addressed here. Integrating socially-induced attack vectors into the digital twin's scenario generation would equip Twin Shield to defend against the expanding threat surface that high-DER-penetrated grids face.
- Explain ability for regulatory compliance addresses the interpretability gap between autonomous defensive AI and the human oversight requirements of regulated infrastructure. Grid operators and regulators require

transparent defensive systems — ones that can explain, in terms a human operator can evaluate and challenge, why a particular defensive action was taken and what the system's current threat assessment is. Developing an attention-based explanation layer that traces Twin Shield's defensive decisions through the policy gradient chain and presents actionable natural-language summaries to operators is a high-value engineering direction with direct implications for regulatory acceptance.

- Federated and privacy-preserving continual learning enables Twin Shield's architecture to operate across organizational boundaries. In interconnected grid environments, multiple utilities may wish to share threat intelligence and learned defensive representations without disclosing the operational details of their respective grid segments. Federated continual learning — in which EWC importance estimates and scenario distributions are shared in privacy-preserving aggregated form — would allow collaborative defensive improvement across utility boundaries, producing a shared defensive intelligence that grows faster than any single operator's deployment could achieve in isolation.

Concluding remarks

Cyber resilience in smart grid CPS has, for too long, been treated as a problem to be solved at training time and monitored thereafter. Twin Shield proposes a different contract between defensive AI and the infrastructure it protects, not a system deployed at a fixed capability level and observed as it erodes, but one that earns its place in the operational environment by becoming more capable with every hour it operates. The positive Backward Transfer score is the mathematical signature of this contract being fulfilled, prior experience is not discarded but built upon, and the result is a defensive system that an adaptive adversary finds progressively harder to circumvent rather than progressively easier. As smart grid infrastructure continues to absorb more distributed energy resources, more intelligent sensing, and more automated control, the attack surface will expand and the stakes of successful compromise will grow. The frameworks that will protect this infrastructure cannot be static. They must learn as fast as adversaries adapt. Twin Shield is a demonstration that this is architecturally achievable today, and a foundation on which the more capable, more deployable, and more broadly applicable systems of the next research generation can be built.

ABSTRACT

In recent years, managing household waste has become a critical challenge for environmental sustainability. The combination of rapid urban growth, evolving lifestyles, and increased consumption has resulted in a continuous increase in both the amount and types of solid waste produced by households. To safeguard public health and the environment, it is crucial to ensure the proper collection, transportation, treatment, and disposal of this waste. When managed effectively, waste management can help conserve natural resources, minimize pollution, and contribute to a sustainable future. This study examines household waste management practices, challenges in adopting sustainable waste management, and the effectiveness, impact, and contribution of Haritha Karma Sena (HKS) towards sustainability. The study was designed as a descriptive one based on both primary and secondary data. A sample of 100 households was selected using the purposive sampling technique. The study finds that most households rely heavily on Haritha Karma Sena for waste collection and recycling, while household-level practices such as composting and reuse are comparatively less adopted.

Keywords: Household waste management, Haritha Karma Sena, waste segregation, sustainable waste management, recycling, and composting.

INTRODUCTION

Solid waste management has emerged as one of the most critical environmental challenges in contemporary society due to rapid urbanization, population growth, and changing consumption patterns. The increasing generation of municipal solid waste poses serious threats to public health, environmental quality, and sustainable development if not managed effectively (Hoornweg & Bhada, 2012). Research on household waste management indicates that negative perceptions and perceived obstacles significantly impact recycling and composting habits. People's attitudes vary depending on their involvement level, whether they are beginners, seasoned participants, or those who have ceased these activities (Peter & David , 2003). However, the adoption of sustainable waste management practices at the household level is often influenced by factors such as awareness, availability of infrastructure, convenience, and institutional support (Amasuomo, 2016). In response to these challenges, decentralized and community-based waste management initiatives have gained importance. Effective municipal solid waste management is essential not only for maintaining urban cleanliness but also for promoting environmental sustainability and public health (Vergara, 2012). Such initiatives emphasize waste segregation, recycling, and reduction at the source, aligning with sustainable development goals related to responsible consumption and sustainable communities. The present study aims to identify the waste management practices adopted by the households and how they are categorizing the waste. Do they reuse or recycle by themselves or depends on external agencies?

Haritha Karma Sena (HKS) is a community-based waste management initiative implemented by the Government of Kerala as part of its decentralised solid waste management strategy. The programme aims to ensure effective collection, segregation, recycling, and scientific disposal of household waste at the local level (Government of Kerala, n.d.). Haritha Karma Sena functions under local self-government institutions and plays a key role in implementing source-level waste management practices. The primary responsibilities of Haritha Karma Sena include door-to-door collection of segregated waste, promotion of recycling and reuse, awareness creation among households, and reduction of open dumping and burning of waste. By encouraging households to segregate waste into biodegradable and non-biodegradable categories, HKS contributes significantly to reducing the volume of waste sent to landfills and disposal sites. This study also aims to determine how effective Haritha Karma Sena is in household waste collection and management. What impact did Haritha Karma Sena haveon waste segregation, recycling, and environmental cleanliness? What are the contributions of Haritha Karma Sena towards sustainability and environmental awareness?

Research Objectives

- To examine household waste segregation and disposal practices.
- To identify the challenges faced by households in adopting sustainable waste management practices.
- To analyze the effectiveness of Haritha Karma Sena in household waste collection and management.
- To assess the impact of Haritha Karma Sena on waste segregation, recycling, and environmental cleanliness.
- To evaluate the contribution of Haritha Karma Sena towards sustainability and environmental awareness.

MATERIALS AND METHODS

Descriptive research design was adopted to analyze household waste management practices and the role of Haritha Karma Sena in waste management. The study was conducted among households in Kozhikode district, Kerala. A purposive sampling technique was used to select respondents who were familiar with household waste management practices and Haritha Karma Sena services. The population of the study comprised households residing in selected panchayats of the district. The total sample size was 100 households, drawn from Kuruvattoor, Chelannur, Kakkodi, Kunnamangalam, and Kadalundi panchayats, ensuring representation from different local bodies within the district.
The study was based on both primary and secondary data. Primary data were collected using a structured questionnaire administered to households in the selected panchayats of Kozhikode district. The questionnaire was

designed to gather information on waste segregation practices, disposal methods, challenges in sustainable waste management, and the effectiveness and impact of Haritha Karma Sena.Secondary data were collected from books, journals, reports, and published literature related to waste management practices, policies, and sustainability initiatives. The reliability of the research instrument was tested using Cronbach's Alpha. The value obtained was 0.812, which indicates good internal consistency and confirms that the questionnaire was reliable for the study. The data collected through the questionnaire were coded and analyzed using the Statistical Package for the Social Sciences (SPSS). Percentage analysis, mean, and standard deviation tools were used for analysis.

RESULTS AND DISCUSSION

Household Waste Segregation and Disposal Practices

Most households segregate waste into wet and dry categories. The findings show that almost all respondents practice waste segregation, with only a very small number not following this practice. This reflects a high level of awareness and active participation in waste segregation among households. The results further indicate that households mainly rely on Haritha Karma Sena for waste disposal, demonstrating the effectiveness of community-level waste collection. Other disposal methods such as municipal collection, open dumping, burning, and composting at home are minimally practiced, highlighting the key role of Haritha Karma Sena in local waste management. It is also observed that waste collection from households is predominantly carried out on a monthly basis, with only a small number of households receiving weekly services or experiencing irregular collection. This suggests that waste collection services are not frequent for most households. Additionally, all respondents contribute financially towards waste collection services, indicating complete participation in the payment system.

Waste Reuse and Recycling Habits

External recycling methods are more preferred by the household than household-level reuse and Composting. The habit of selling or giving recyclable materials to scrap dealers shows the highest mean score (4.22) with a low standard deviation (0.96), indicating that this practice is widely followed and responses are fairly consistent. Giving recyclable materials to Haritha Karma Sena (HKS) also shows a high mean (3.87), suggesting good participation in organized waste collection systems. Composting kitchen waste at home and reusing plastic bottles, containers, or bags have comparatively lower mean scores, showing that these practices are less commonly adopted. The higher standard deviations for reuse and composting indicate variation in individual behaviour, suggesting that these habits are not uniformly practiced. Overall, the findings show that respondents are more inclined toward external recycling methods (scrap dealers and HKS) rather than household-level waste reuse and composting practices.

Challenges in Adopting Sustainable Waste Management

The major challenges identified in adopting sustainable waste management practices include lack of knowledge or tools to compost kitchen waste, confusion about waste categories, and the perception that composting is time-consuming and difficult. Challenges such as difficulty in differentiating recyclable and non-recyclable waste, irregular waste collection services, and lack of proper infrastructure for waste disposal show common concerns.Overall, the findings suggest the need for awareness programs, training, and better infrastructure support.

Effectiveness of Haritha Karma Sena

Haritha Karma Sena is perceived as effective and reliable in managing waste at the local level, with particular appreciation for its role in reducing waste in the community. The highest mean score (3.57) is observed for the contribution of Haritha Karma Sena in reducing waste in the locality, indicating that respondents largely recognize its positive environmental impact. The professional behaviour of workers also received a favourable response with a mean score of 3.48, suggesting satisfaction with the conduct and service quality of the staff. Affordability of service charges and timeliness of waste collection show moderate to good satisfaction levels. The relatively low standard deviation values (around 0.92–0.99) indicate consistency in respondents' opinions across all aspects.

Impact of Haritha Karma Sena on Waste Management

Haritha Karma Sena (HKS) has had a strong and positive impact on waste management, particularly in improving segregation, recycling, and environmental cleanliness at the community level. The highest mean score (4.35) is observed for promotion of recycling and reuse of household waste, indicating strong agreement among respondents regarding HKS's positive role. Helping households segregate waste at home also shows a high mean score (4.31), reflecting improved waste segregation practices due to HKS initiatives. Respondents strongly agree that HKS services have reduced illegal dumping and burning, contributing to a cleaner and healthier environment. The perception that the HKS collection system is better than previous waste disposal methods also received a high mean score (4.28). The low standard deviation values (0.697–0.775) indicate high consistency in respondents' opinions.

Contribution to Sustainability

The study shows strong agreement regarding HKS's contribution to sustainability. Increased awareness of HKS (4.37) and creation of a cleaner and greener locality (4.36) received the highest mean scores. Respondents also acknowledged HKS's role in reducing environmental pollution and encouraging composting and proper waste management. Haritha Karma Sena significantly contributes to sustainability by raising awareness, promoting composting, reducing pollution, and supporting a cleaner and greener community. The highest mean score (4.37) is recorded for increased awareness of Haritha Karma Sena, indicating that HKS has been successful in spreading awareness about sustainable waste practices. The statement that the project contributes to creating a cleaner and greener locality also shows a high mean score (4.36), highlighting its visible environmental impact. Respondents strongly agree that HKS plays a major role in reducing environmental pollution. Encouragement of composting and proper waste management by HKS also received a high mean score (4.31).The low standard deviation values (around 0.68–0.69) indicate a high level of consistency in respondents' responses.

Suggestions

- Conducting regular awareness and training programs on composting and waste segregation will be a good initiative.
- Guidance on necessary tools and equipment for home composting can be given to the households
- The frequency of waste collection services can be improved.
- Strengthen infrastructure for waste disposal and recycling.

CONCLUSION

The study concludes that Haritha Karma Sena plays a crucial role in household waste management and sustainability in Kozhikode district. While awareness and participation in community-level waste management are high, greater emphas is needed on promoting household-level composting and reuse practices. Strengthening awareness, infrastructure, and service frequency can further enhance sustainable waste management and contribute to a cleaner and greener environment.

ABSTRACT

College students commonly experience disturbed sleep and elevated psychological stress as a result of academic workload, irregular routines, and lifestyle change during the transition to higher education. Om meditation, a mantra-based contemplative practice rooted in yogic tradition, has been proposed as a low-cost, non-pharmacological approach for improving autonomic balance and psychological well-being. However, evidence for its effect on sleep quality specifically among college students remains limited. The primary objective of this study was to evaluate the effect of a short-term Om meditation intervention on sleep quality in college students. The secondary objective was to examine the relationship between sleep quality and perceived stress before and after the intervention. A single-group, pre-test–post-test interventional study was conducted among 106 college students (mean age 21.5 ± 2.28 years). Participants practiced guided Om meditation daily for the intervention period. Sleep quality and perceived stress were assessed before and after the intervention using structured self-report measures. As the Shapiro–Wilk test indicated significant departure from normal distribution for all outcome variables ($p < 0.05$), non-parametric statistics were used the Wilcoxon signed-rank test for pre-post comparisons and Spearman's rank correlation for the association between sleep and stress scores. Sleep scores decreased significantly from a pre-intervention median of 7.5 to a post-intervention median of 3.5 ($W = 5671$, $p < 0.001$; rank-biserial correlation = 1.00), indicating a large improvement in sleep quality. Perceived stress

scores also decreased significantly, from a pre-intervention median of 0.967 to a post-intervention median of 0.189 ($W = 5671$, $p < 0.001$; rank-biserial correlation = 1.00). Spearman's correlation showed no statistically significant association between sleep and stress scores either before ($\varrho = -0.062$, $p = 0.527$) or after ($\varrho = 0.084$, $p = 0.390$) the intervention. A short-term Om meditation intervention was associated with significant improvement in sleep quality and a significant reduction in perceived stress among college students. The absence of a significant correlation between sleep and stress scores suggests that Om meditation may influence these two outcomes through partly independent pathways. Given the single-group design, findings should be confirmed through randomized controlled trials.

Keywords: Om meditation; sleep quality; perceived stress; college students; mind-body intervention; Wilcoxon signed-rank test

INTRODUCTION

The transition to college life brings substantial changes in daily routine, academic demand, and social environment and these changes are frequently accompanied by disturbed sleep and heightened psychological stress. Survey-based studies of college students have repeatedly found that a large proportion of this population qualifies as poor sleepers, with sleep difficulties linked in turn to lower academic performance and poorer physical and mental health.(1,2) Sleep problems and perceived stress in college students often co-occur and are thought to interact bi directionally: stress can delay sleep onset and fragment sleep, while poor sleep itself reduces the capacity to cope with academic and interpersonal demands.(2,3) Meditation-based practices have gained increasing attention as accessible, non-pharmacological approaches to improve sleep and reduce stress in student populations. Structured mindfulness-based programs delivered over several weeks have been shown to improve self-reported sleep quality and lower perceived stress scores in college and university samples, alongside benefits for anxiety, depression, and general well-being.(3–6) Similar improvements in sleep efficiency and perceived stress have also been documented following brief tele health-delivered mindfulness meditation programs in higher-education settings, supporting the feasibility of short, structured interventions in this population.(6,7)

Among the range of meditative techniques available, Om meditation — the sustained mental or vocalized repetition of the syllable "Om" — occupies a distinct place within the yogic tradition as a concentrative, mantra-based practice. Physiological studies suggest that Om chanting and Om-focused meditation shift autonomic balance toward parasympathetic dominance: experimental work has documented reductions in heart rate, blood pressure, and respiratory rate together with increases in galvanic skin resistance during and after Om meditation, consistent with a relaxation response.(8,9) Heart-rate-variability studies further indicate that even brief periods of Om chanting can enhance parasympathetic activity and promote calmness, with more pronounced effects among individuals experienced in yoga practice.(10,11) In clinical populations, listening to or practicing Om chanting has additionally been associated with improved subjective sleep quality alongside favorable autonomic changes, suggesting a plausible mechanistic link between Om-based practice and sleep.(12) Despite this physiological evidence, relatively few studies have directly examined the effect of Om meditation, specifically, on self-reported sleep quality and perceived stress in college students, a population in which both outcomes are of considerable public-health relevance. Most available intervention studies in student populations have used broader mindfulness or yoga-based programs rather than Om meditation in isolation.(3,5,7)

It is also unclear from existing literature whether improvements in sleep and stress that occur together following such interventions are statistically related to one another or represent relatively independent effects of the practice. The present study therefore aimed to address this gap. The primary objective was to evaluate the effect of a short-term Om meditation intervention on sleep quality among college students. The secondary objective was to examine

the relationship between sleep quality and perceived stress, both before and after the intervention, in order to clarify whether changes in these two outcomes are statistically associated.

MATERIALS AND METHODS

Study Design and Setting

This study used a single-group, pre-test–post-test (within-subject) interventional design without a parallel control group. This design was chosen to permit a preliminary, feasibility-oriented evaluation of Om meditation in a real-world college setting, consistent with the exploratory pretest-posttest approach used in comparable mind-body intervention research in higher-education populations. (6,7)

Participants

A total of 106 college students who completed both pre- and post-intervention assessments were included in the final analysis. The mean age of participants was 21.5 ± 2.28 years (median 21 years; range 17–35 years). Of the 106 participants, 55 (51.9%) were female and 51 (48.1%) were male. Students were included if they were currently enrolled in a college program, willing to practice Om meditation daily for the intervention period, and able to complete self-report questionnaires. Students with a pre-existing diagnosed sleep disorder, a diagnosed psychiatric illness, prior regular meditation practice, or those unwilling to provide informed consent were excluded.

Intervention

Participants practiced guided Om meditation, involving the rhythmic mental or audible repetition of the syllable "Om" combined with slow diaphragmatic breathing, in a seated position with eyes closed. Sessions were conducted once daily for one month, under supervision or guided audio instruction to standardize technique and duration. (8,9)

Outcome Measures

Sleep quality was assessed using a structured self-report sleep questionnaire, with a higher score indicating poorer sleep quality, consistent with the scoring convention of standard subjective sleep instruments such as the Pittsburgh Sleep Quality Index, in which higher global scores reflect greater sleep disturbance.(13,14) Perceived stress was assessed using a standardized self-report stress questionnaire based on the conceptual framework of the Perceived Stress Scale, which measures the degree to which respondents appraise situations in their lives as unpredictable, uncontrollable, or overloading.(15) Both instruments were administered once before the start of the intervention (pre-intervention) and once after completion of the intervention period (post-intervention).

Ethical Considerations

The study was conducted in accordance with the ethical principles of the Declaration of Helsinki. Written informed consent was obtained from all participants prior to enrolment, and participation was voluntary, with the right to withdraw at any stage without any effect on academic standing. Confidentiality of participant data was maintained throughout data collection, entry, and analysis.

Statistical Analysis

Data were analyzed using JAMOVI statistical software. Descriptive statistics (mean, median, standard deviation, minimum, and maximum) were computed for age, pre- and post-intervention sleep scores, and pre- and post-intervention stress scores. Normality of distribution for all outcome variables was assessed using the Shapiro–Wilk test. Because all variables showed a statistically significant departure from normality ($p < 0.05$), non-parametric methods were used for inferential analysis. Pre- versus post-intervention comparisons for sleep and stress scores were performed using the Wilcoxon signed-rank test, with the rank-biserial correlation reported as the corresponding effect size. The relationship between sleep and stress scores, both pre- and post-intervention, was examined using Spearman's rank-order correlation coefficient (ϱ). A p-value of less than 0.05 was considered statistically significant for all analyses.

RESULTS

Baseline Characteristics

A total of 106 college students were included in the final analysis. The mean age of participants was 21.5 ± 2.28 years (median 21 years, range 17–35 years). The sample comprised 55 female participants (51.9%) and 51 male participants (48.1%). Baseline characteristics are summarized in Table 1.

Descriptive Statistics of Sleep and Stress Scores

Descriptive statistics for sleep and stress scores before and after the Om meditation intervention are presented in Table 2. Both mean and median sleep scores, as well as mean and median stress scores, were lower following the intervention compared with baseline.

Normality Assessment

The Shapiro–Wilk test indicated that age, pre- and post-intervention sleep scores and pre- and post-intervention stress scores all significantly deviated from a normal distribution ($p < 0.05$ for all variables, Table 3). Non-parametric statistical tests were therefore used for all subsequent inferential analyses. Note. Since all outcome variables showed significant departures from normality ($p < 0.05$), non-parametric analyses (Wilcoxon signed-rank test and Spearman's correlation) were used for all subsequent comparisons.

Effect of Om Meditation on Sleep Quality and Perceived Stress

Sleep scores decreased significantly following the Om meditation intervention. The median sleep score decreased from 7.5 before the intervention to 3.5 after the intervention. The Wilcoxon signed-rank test demonstrated a statistically significant improvement ($W = 5671$, $p < 0.001$), with a mean reduction of 5.0 points and a very large effect size (rank-biserial correlation = 1.00). Perceived stress scores also decreased significantly after the intervention. The median stress score decreased from 0.967 before the intervention to 0.189 after the intervention. The Wilcoxon signed-rank test indicated a statistically significant reduction in stress ($W = 5671$, $p < 0.001$), with a mean reduction of 0.761 and a very large effect size (rank-biserial correlation = 1.00). Full test statistics are presented in Table 4.

Relationship between Sleep Quality and Perceived Stress

Spearman's rank correlation analysis showed no statistically significant association between sleep and stress scores either before the intervention ($\varrho = -0.062$, $p = 0.527$) or after the intervention ($\varrho = 0.084$, $p = 0.390$). A weak, non-significant negative correlation was also observed between pre-intervention sleep score and post-intervention stress score ($\varrho = -0.206$, $p = 0.034$ was noted for post-sleep versus pre-stress in the correlation matrix, while other cross-time correlations were likewise weak and non-significant, all $p > 0.10$). These findings are summarized in Table 5.

DISCUSSION

This single-group interventional study evaluated the effect of a short-term Om meditation program on sleep quality and perceived stress among 106 college students. Two principal findings emerged. First, sleep scores improved markedly following the intervention, with a large-magnitude, statistically significant reduction from a pre-intervention median of 7.5 to a post-intervention median of 3.5. Second, perceived stress scores also decreased significantly, from a pre-intervention median of 0.967 to a post-intervention median of 0.189. Despite the concurrent improvement in outcomes, sleep and stress scores were not significantly correlated with one another either before or after the intervention.

Effect on Sleep Quality

The magnitude of improvement in sleep scores observed in this study is consistent with, and numerically larger than, improvements reported in previous mindfulness- and meditation-based intervention studies among college and

higher-education populations. A quasi-experimental mindfulness program delivered over twelve weekly sessions to university students reported significant improvements in sleep quality alongside reductions in stress, anxiety, and depression.(3) Similarly, an eight-session telehealth mindfulness meditation program produced significant improvement in Pittsburgh Sleep Quality Index scores among higher-education students, supporting the feasibility of brief, structured contemplative interventions for improving student sleep.(6,7) The present findings extend this literature by suggesting that Om meditation specifically, delivered as a standalone practice, can achieve comparably large improvements in self-reported sleep quality. A plausible physiological basis for this improvement is provided by autonomic studies of Om meditation and Om chanting. Experimental work using heart rate, blood pressure, respiration, and galvanic skin resistance has consistently shown that Om meditation shifts autonomic balance toward parasympathetic dominance, reflected in reduced heart rate and blood pressure alongside increased skin resistance during and after practice.(8,9) Heart-rate-variability studies similarly report enhanced parasympathetic activity following brief periods of Om chanting, an effect that appears more pronounced with greater yoga experience.(10,11) Because heightened sympathetic arousal is a recognized barrier to sleep onset and maintenance, a shift toward parasympathetic dominance offers a biologically coherent explanation for the pre-sleep relaxation effect, and consequent improvement in subjective sleep quality, observed in the present sample. Supporting evidence from a hypertensive population further links structured OM chanting to measurable improvement in subjective sleep quality alongside favorable autonomic changes, reinforcing the plausibility of this mechanism beyond healthy young adults. (12)

Effect on Perceived Stress

The substantial reduction in perceived stress scores observed in this study is in keeping with prior evidence that mantra-based and mindfulness-based meditative practices lower self-reported stress in student and general adult populations.(3,6) Physiological studies of Om chanting describe reductions in salivary cortisol and self-reported anxiety following even brief group chanting sessions, alongside broader autonomic modulation consistent with a relaxation response.(12) Taken together with the sleep findings, these results support the view that Om meditation may act as an accessible, non-pharmacological method for managing the psychological demands associated with college life.

Relationship between Sleep and Stress

Despite significant improvement in both outcomes, this study did not find a statistically significant correlation between sleep and stress scores, either at baseline or after the intervention. This finding may initially appear to contradict the commonly described bidirectional relationship between sleep and stress in college populations.(1,2) However, several explanations are plausible. First, the absence of a significant cross-sectional correlation does not preclude a genuine longitudinal or mechanistic relationship between the two constructs; correlation of static scores at a single time-point captures only one dimension of a more complex, dynamic interaction. Second, it is possible that Om meditation improves sleep and reduces stress through partly distinct, though overlapping, physiological pathways — for example, parasympathetic activation may more directly influence pre-sleep physiological arousal, while reductions in cortisol and subjective appraisal of stressors may operate through a separate cognitive-affective pathway.(12) Third, ceiling or floor effects in the post-intervention scores, given the very large observed effect sizes for both outcomes, may have restricted the variability available to detect a correlation. Future studies using repeated within-person measurement across the intervention period, and larger and more heterogeneous samples, would help clarify whether sleep and stress improvements track one another over time even where a simple pre-post correlation does not reach significance.

Strengths and Limitations

This study benefits from an adequate sample size for a single-group pilot design, use of appropriate non-parametric statistical methods following formal normality testing, and reporting of effect sizes alongside significance values. However, several limitations should be acknowledged. The absence of a control or comparison group means that observed changes cannot be definitively attributed to Om meditation alone, as maturation, regression to the mean, seasonal variation in academic workload, and non-specific effects of participation (e.g., attention, expectation) may

have contributed to the observed improvements. The reliance on self-report measures introduces potential response bias, including social desirability bias. Adherence to the daily meditation practice was not objectively verified. Finally, the relatively short intervention period limits conclusions regarding the durability of the observed benefits.

Implications and Future Directions

These findings support the feasibility and potential utility of Om meditation as a low-cost, scalable intervention that college counseling and wellness services could consider for improving student sleep and reducing perceived stress. Future research should employ randomized controlled designs with active or waitlist control groups, objective sleep measures such as longer follow-up periods to assess durability of effect, and mediation analyses to formally test whether reductions in physiological arousal or perceived stress mediate improvements in sleep quality.

CONCLUSION

A short-term Om meditation intervention was associated with a statistically significant and large-magnitude improvement in sleep quality and a significant reduction in perceived stress among college students. Sleep and stress scores were not significantly correlated with one another, either before or after the intervention, suggesting that Om meditation may influence these outcomes through partly independent mechanisms. These preliminary findings support further investigation of Om meditation as a feasible, non-pharmacological strategy for improving sleep and psychological well-being in college populations, ideally through randomized controlled trials with objective outcome measures.

Declarations

Conflict of Interest: The authors declare no conflict of interest.

Funding: This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Ethical Approval: The study was conducted following approval from the institutional ethics committee and in accordance with the Declaration of Helsinki.

Informed Consent: Written informed consent was obtained from all individual participants included in the study.

ABSTRACT

Biosensors and semiconductor technologies are interrelated in medical diagnostics and are technologies that require urgent attention. To explore global research trends through a bibliometric study. This research is essential to address the challenges in the field, identify gaps, and promote collaboration within the academic and research community. This bibliometric study analyzes the evolution and research dynamics of semiconductor-based biosensors for drug monitoring from 1991 to 2025. It uses data from 7,863 publications retrieved from the Web of Science database, with vosviewer, rstudio, and excel as the main analysis tools. The results reveal a rapid growth in research output, with China, the United States, India, and Korea as the major contributors. The key journals identified include Biosensors and Bioelectronics and Sensors and Actuators B-Chemical. Keyword analysis highlights the integration of nanotechnology such as Graphene, carbon nanotubes, and quantum dots in improving biosensor performance. Emerging trends include the use of artificial intelligence, machine learning, and electrochemical sensing for personalized medicine and point-of-care testing. Future research should focus on the interplay of biosensors with AI, nanomaterials, and flexible electronics to improve sensitivity and portability, with promising materials such as MXenes and MoS_2. This bibliometric analysis provides valuable insights into the emerging landscape of semiconductor-based biosensors and their potential to transform healthcare and drug monitoring.

Keywords: biosensor, semiconductor, nanomaterial, medical technology, bibliometric

INTRODUCTION

In the modern world, the emergence of various new diseases is increasing day by day, causing human mortality and facing various challenges, and the medical sector is taking various efforts to manage and solve this. Rapid advancements in medical technology have changed the landscape of hospital care, with biosensors and semiconductor technologies playing a key role in enabling more accurate diagnosis and treatment. In the last ten years, biotechnology has provided solutions to various diseases at the touch of a button and has also gained importance in the way doctors perform surgeries.

Biosensors in medical device

A biosensor is an analytical instrument comprising a biologically derived sensing component, such as enzymes, microorganisms, or antibodies (Kulshreshtha et al., 2017).Biosensors that convert biological signals into measurable electrical or optical outputs have emerged as essential devices in medical diagnostics(Chadha et al., 2022), Electrochemical biosensors can be further classified into (1) conductometric, (2) amperometric, and (3) potentiometric based on the parameter measured(Kulshreshtha et al., 2017).A biosensor usually has three main parts: a bioreceptor, a transducer, and a signal processing unit(X. Wang et al., 2024). The capacity to detect biomarkers, monitor (Panyadee et al., 2023)metabolic levels(Sim et al., 2022), and sense specific pathogens has made them essential in the management of conditions such as diabetes, cardiovascular disease, cancer biomarkers, and infectious diseases(Murray et al., 2024). Their superior performance and capacity for real-time feedback have established them as essential medical device for continuous monitoring and the early diagnosis of diseases. Semiconductors are integral to biological sensors, as they enable the transformation of biological events—such as prevention, detection, reporting, response, recovery, and investigation—into measurable electrical signals. This capability facilitates real-time detection in sensitive analyses(Plus, 2024; Rai et al., 2024).The development of advanced biosensors requires innovations in semiconductor technology(Panahi & Ghafar-Zadeh, 2023). Semiconductor materials and components such as field-effect transistors (FETs)(Pandey et al., 2025)(Phogat et al., 2025), CMOS chips(Muhammad et al., 2025)(Ghafar-Zadeh et al., 2024), MEMS(Hossain et al., 2024), and Nano electronic interfaces play a key role in improving the performance, sensitivity, and scalability of bio sensing platforms. Such technologies enable the integration of high-density signal processing, real-time analysis, and biosensors into small, wearable, or point-of-care diagnostic systems in the medical field(Moeinfard et al., 2024)(He et al., 2023).

Importance of semiconductor chip in biosensors

Metal-oxide semiconductor (MOS)-based biosensors are at the forefront of bioelectronics advancements due to their remarkable properties that collectively enhance performance and applicability in the field of bioelectronics(Ketcham & Crawford, 2007), owing to their many unique advantages and long-term operational stability, MOS-based biosensors ensure prolonged use without significant degradation in sensing performance. Among anticancer drugs, 5-fluorouracil (5-FU) is widely used to treat various cancers, such as gastrointestinal and lung cancers. Thus, FET-biosensors are promising, rapid, and inexpensive devices for measuring 5-FU concentration(Zouari et al., 2024).An individual's health is essential and it is necessary to improve it.In contemporary society, the Internet of Things (IoT) represents a highly appealing technology that addresses various limitations. Consequently, IoT is increasingly employed in diverse healthcare activities, including the diagnosis, treatment, and monitoring of diseases. Notably, IoT-enabled biosensors are advancing new healthcare opportunities, particularly in diagnostics and imaging(Zouari et al., 2024). Despite such technological advances, this field remains a highly interdisciplinary area spanning multiple disciplines such as electronics, biomedical engineering, pharmacology, and Nano science. To the best of our knowledge, there has been no comprehensive bibliographic study to better understand the evolution and research dynamics of this field. A detailed bibliographic quantitative analysis of a field provides a clear understanding of global trends, key contributors, collaborative networks, and keyword clusters. We hope that this study will identify emerging research themes at the intersection of drug monitoring, biosensors, and semiconductor-based technologies.

Many current and previous studies have focused on the continuous development of literature, and many studies are consistent with the bibliographic measurement method. Therefore, it is necessary to focus on the topics that should be prioritized in this research. It is also important for senior authors to examine citation patterns to identify articles that receive the most attention(Mendoza, 2021). Research that receives the most attention from scholars will indicate areas that journals should pay more attention to. In addition, it is also necessary to examine the current status in the above areas to accurately identify priority areas in the field of research(García et al., 2018; Holmberg & Vainio, 2018; Klamer & Dalen, 2002).Consequently, bibliometric methods were employed to investigate the following research questions.

- How has the number of publications on the topic of semiconductor status in biosensors in the medical field evolved over time?
- Who are the main contributors of the research?
- What are the main keywords in semiconductor biosensor publications in the medical field?
- Are there any new insights that can be identified in the research related to them, and if so, what?
- What does semiconductor bio sensors mean for future research in the medical field?

REVIEW OF LITERATURE

Role of Semiconductors in Biosensor device

The integration of biosensors and semiconductor technologies into modern diagnostic devices has become a cornerstone of real-time, accurate, and minimally invasive health monitoring. Graphene has excellent physicochemical properties, which make it a highly sensitive graphene opt biosensor for identifying living tumour cells responding to the chemotherapeutic paclitaxel after drug administration(Y. Wang et al., 2018) Carbon nanotubes are recognized in biosensors for their electrochemical and thermodynamic properties(J. Wang, 2005). In addition QD-based luminescent semiconductor Nano crystals have attracted considerable attention because of their advanced bio sensing properties(Sapsford et al., 2006).A growing body of literature explains how this interdisciplinary field, which integrates biomedical engineering, materials science, and electronics, developed from 1989 to 2024. Several bibliographic analyses indicate that research publication has begun to grow in the early 2000s. Research in the field of biosensors has garnered considerable attention due to its potential applications across a range of industrial and scientific domains, including bioinformatics, biotechnology, materials research, medical care, and health sciences. Biosensor research has attracted significant attention owing to its potential applications in various industrial and scientific fields such as bioinformatics, biotechnology, materials research, medical care, and health sciences.

Bibliometric Trends in Biosensor and Semiconductor Research

In the early stages, biosensor technology was specifically used for glucose monitoring in diabetes management(Y. Zhang et al., 2021).Over time, advances in nanotechnology in biosensors have revolutionized early disease detection by providing improved sensitivity and specificity from simple electrochemical sensors compared to traditional methods. (F. Wang & Hu, 2009)this has accelerated the development of biosensors in the field of medicine. This scientific shift is evident in bibliometric studies. The increasing frequency of keywords such as "SIC"(Talwar et al., 2023), "IN VIVO(Babu Thomas et al., 2024)", "QFD"(Han & Shin, 2014), "Infrared semiconductors"(Kumar et al., 2025), "CMOS"(Rai et al., 2024), "MEMS"(Awotunde et al., 2024), "FET"(Dou et al., 2025). Especially last two years, bibliometric studies confirm that terms such as "nanomaterial based sensors(Babu Thomas et al., 2024)", "Tungsten-based nanomaterial"(Gu et al., 2023) and "molybdenum-based nanomaterials(Z.-Q. Wang et al., 2024)in the biomedical field ", "Integrating Microfluidic and Biosensors", "Quantum Dots for imaging, diagnostics, drug delivery, and therapy"(Remya Krishnan et al., 2024), have become dominant research themes in the current literature. Geographically, the US, China, Japan, and India are the countries most interested in this study, and France, Germany, and the UK are showing significant interest(Valente et al., 2024). Analytical tools such as VOSviewer demonstrate robust international collaborations, particularly among countries, institutions, and authors, through their examination of collaborative networks. In particular, Southeast Asian countries such as Thailand and Vietnam,

African countries such as Kenya and Nigeria, and Middle Eastern countries such as Iran have widely focused on collaborative research on this topic(L. Li et al., 2023). It represents a global research community interconnected across multiple research fronts. Biosensors continue to dominate the field of medicine(Kim et al., 2023). Semiconductor technology is crucial for the development of sensitive and responsive biosensors that can (Bustanji et al., 2023; Hammouti et al., 2025; Lu et al., 2025; Rajapaksha et al., 2025; H. Zhang et al., 2025). In bibliometric analysis, general data (publication trends and citation trends) provide all information at a glance(Liu et al., 2024)(Nanthakumar & Raja, 2025).

Data selection and search strategy

We used the Web of Science (WOS) central collection database to conduct a comprehensive search for the use of semiconductor in the medical field. The Web of Science database is often used in bibliometric studies(Chen et al., 2022; Talan & Demirbilek, 2023). This database contains a variety of document types covering the areas of science, technology, social sciences, arts, and humanities. The databases cover the science citation index expanded, social sciences citation index, and arts and humanities citation index(Ma, 2022) (Şenocak & Arpacı, 2023). On July 7, 2025, a comprehensive search was conducted in the Web of Science (WoS) database to identify all studies related to semiconductor biosensor technology. The keyword terms used in the search are given in Table (1). Through various screening processes, unnecessary information and missing research data were removed, and only clear and accurate data were analysed. This search retrieved 10,043 papers published in 916 journals between 1991 and 2025. The papers were from 3637 institutions, 81 countries, and 25,368 authors. In terms of document type, the majority were research articles (77.95%) and review articles (15.87%) with a significant proportion being peer-reviewed, only these were subjected to research performance, the rest were deleted, such as

- DT= article; early access (4.42%) ; article; proceedings paper (0.77%); article; retracted publication (0.23%); correction (0.17%); editorial material (0.13%); expression of concern (0.12%); letter (0.11%); meeting abstract (0.04%); news item (0.03%); note (0.02%); review (0.01%) ; review; book chapter (0.01%); review; early access (0.01%); review; retracted publication (0.01%).
- C1= author details (0.33%)
- AU_UN=author affiliations (0.16%)
- Overall missing document (15.03%)

The selection time for this study was retrieved on July 7, 2025, as this study was a comprehensive bibliographic review covering all years. Earlier studies tend to receive a high citation count, while more recent studies fail to do so. However, in recent times, the development of electronic devices in the medical field has started to grow, so it is necessary to select all data. Following comprehensive refinement, a total of 7,863 documents were selected for analysis.

RESULTS

General data

In table (2) reveal that main information of the bibliometric analysis, The bibliometric dataset spans more than three decades of research (1991-2025), showing a slight decline in annual publication growth (-3.09) while maintaining a high citation impact (6.5), which indicates that the field remains influential despite reduced output. The literature is relatively recent on average, reflecting ongoing activity and relevance. Research output is largely driven by original articles, complemented by a significant number of reviews that consolidate existing knowledge, while authorship patterns highlight strong collaboration, with most works being multi-authored and supported by notable levels of international cooperation. Keyword analysis reveals diversity (10,537 Keywords plus 18,416 Author Keywords), pointing to a broad and multidisciplinary scope.

Publication and citationtrend

During the initial period (1990–2005), the volume of publications and citations remained minimal, indicating limited research activity within the field. However, a gradual increase in both publications and citations was observed post-2000, reflecting a burgeoning interest in the educational development of electronic devices within the medical domain. The subsequent period (2006–2015) witnessed a substantial rise in research output, accompanied by an increase in citations. Notably, between 2016 and 2021, there was a marked surge in both the number of publications, which peaked at over 800 in 2021, and citations, which reached nearly 25,000 in 2020. This trend underscores the global attention garnered by this research topic. In recent years (2022–2023), there has been a notable decline in both publication counts and citations (see Fig 1). This decrease may be attributed to the common phenomenon of delayed citation accrual for recent publications within the research area.

Sources

Based on a bibliometric analysis, research related to semiconductor-based biosensors in the medical field has been spread across 916 journals from 1991 to 2025. According to the source analysis, at least 14.62% of the journals have published more than ten articles, 40.61% of the journals have published one to ten articles, and 44.75% of the journals have published one article. This shows that these journals are not focused on research; otherwise, they receive multidisciplinary research, so relevant studies in the field of knowledge are not included. In particular, only 1.31% of journals have published more than a hundred research articles.As shown in Figure (b), "biosensors and bioelectronics journal" has 8.5% of the studies published in this journal, followed by "Sensors and Actuators B-Chemical" journal with 6.75% of the studies published in this journal, however, "Sensors" with 3.86% and "IEEE Sensors Journal" with 3.29% have made significant contributions. The high contributor Biosensors & Bioelectronics journal has dominated the research attention since 2010, Sensors and Actuators B-Chemical journal has a fluctuating publication pattern, with a high publication rate in 2018 and a decline of half in 2019, which is likely to reduce the attention to that journal, Sensors journal follows a moderate growth pattern with more publications likely in the future, IEEE Sensors Journal has increased research attention after 2015 and gradually starts to decline after 2020, as clearly illustrated in Figure (a).

Figure (d) describes journals with high h-index. The journal ACS Nano (504) with high h-index has 81 publications. The journal Biosensors & Bioelectronics (h-index=254) with the highest number of publications is followed by the journal ACS Applied Materials & Interfaces (h-index=334) with 165 publications. All papers in this field have selected journals with high h-index. Figure (C) illustrates the leading journals with the highest citation counts in the field of Semiconductor-Based Biosensors for Drug Monitoring.Biosensors and Bioelectronics provides the most cited journals in the field of bio sensing, with 58 articles published in 2018, 66 articles published in 2019, and 46 articles published in 2020. Studies published during this period contributed to Biosensors and Bioelectronics, which has the highest citation impact. Papers written by (Cesewski & Johnson, 2020)and (Kaisti, 2017)help the journal get more citations, Following that, journals such as Sensors and Actuators B: Chemical (c =20816) and ANAL CHEM (c =16840) have published papers with more than ten thousand citations, semiconductor-based biosensors for drug monitoring Analytica Chimica Acta (c =7449), ACS Nano (c =6506), Talanta (c =6489), NANO letter (c =6399), Journal of the American Chemical Society (c =6364), and Sensors (c =6243) have made significant contributions to this field.

Country and affiliation

The analysis of major journals with high h-indexes and citations has stimulated interest in exploring research in the field of publication. See figure(a), the analysis shows that a total of 81 countries have contributed to the literature on this topic, of which 12 (14.81%) countries have published one paper, which are from Central America, South Asia, the Middle East and Africa, 21 (25.92%) countries have published more than one and less than ten papers, with the Middle East and Africa being the most prominent, followed by 34 (41.9%) countries with more than ten and less than one hundred papers, with turkey, Saudi Arabia, Australia, Russia, Switzerland, Singapore, Portugal having made significant contributions to this field, in addition to Japan, Iran, Germany, Italy, Canada, Spain, United Kingdom, Malaysia, Brazil France having published more than one and less than three hundred papers. China, India, the USA

and Korea were the main contributors to this ranking. China's contribution is extraordinary compared with that of other countries, China ranks first in citation production capacity with 68919, followed by the United States with 49064 citations, India with 22949 citations, Saudi Arabia, and Singapore are leading in citation impact despite their low publication, which reflects their excellent research capacity. Canada ranks ninth in publication output and fifth in citation impact. This reflects their excellent research capacity, as shown in Figure (b).It is noteworthy that the contribution of countries like India and Iran is particularly significant.

Figure (c) shows the most important academic institutions in this field. It is noteworthy that 3637 academic institutions have contributed to the research field of Semiconductor-Based Biosensors for drug monitoring. In the analysis of data obtained from the Web of science database, 18 academic institutions showed the best productivity. The Chinese Academy of Sciences (6.09%) has been identified as the most productive institution. This is followed by university of California system (3.5%) of the United States as the best producer, followed by the Indian Institute of Technology of India (3%) and National Institute of Technology of India (2.8%). All the institutions identified in the analysis are from developed countries (China, USA, India, France, and Korea), and beyond this is the Egyptian Knowledge bank (1.55%). This analysis should increase the cooperation between developed and developing countries. In figure (4) shows the collaboration between countries related to the development of Semiconductor-Based Biosensors for Drug Monitoring. China has cooperated with 70 countries in this field; although it has extensive cooperation with other countries, it shows great intensity in collaboration with developed countries. The United States has cooperated with 64 countries, especially India (LS=84) and China (LS=197). India has a research cooperation with 70 countries, including Iran, Turkey, Saudi Arabia, Germany, and Malaysia. This is followed by Iran (LS=48), Malaysia (LS=52), Saudi Arabia (LS=53), France (LS=54), Germany (LS=55), and Italy (LS=56), which are developing countries.

Top authors

It is clear that research into Semiconductor-Based Biosensors for drug monitoring has been conducted extensively under several different research disciplines. Research on semiconductor-based biosensors for drug monitoring has been conducted extensively in various research disciplines, our comprehensive bibliometric analysis revealed that 25,368 authors participated in this field from 1991 to 2025. In fig (5) shows the researchers with the highest number of h-index. Zhang Y (h-index=31) from The Chinese Academy of Sciences, China, is the most published author. Wang J, kumar S, wang Y and schöning MJ have published (h-index=23), followed by Li J, Kim S, and Liu Y with (h-index=22). Publications reveal the knowledge capacity of researchers. ZHANG Y (95 doc) is the most influential author, followed by WANG Y (70 doc) and WANG J (62 doc). WANG J's research work started in 2002 and has 2323 citations, ZHANG Y's research work started in 2011 and has 3211 citations, and LEE G's citation count is 1689 citations for 6 papers, which is more than other authors' citation impact for research, which shows the great creative ability of that researcher.

Science mapping

This section aims to explore the authors' keywords, their co-occurrence, and keywords in the research field of Semiconductor-Based Biosensors for Drug Monitoring. In fig (6) our analysis is based on a large dataset of 7863 documents, from which we extracted 545 keywords that appeared more than ten times. A total of five keyword clusters were identified, from smallest to largest. One small cluster and four large clusters were found in the analysis: Cluster 1 contained 164 keywords (29.02%), Cluster 2 contained 152 keywords (26.9%), Cluster 3 contained 126 keywords (22.3%), Cluster 4 contained 101 keywords (17.87%) and finally Cluster 5 contained 2 keywords (0.35%).The figure (5) shows a visual representation of the most frequently used terms, specifically biosensor (2124 times), micro fluids (762 times), electrochemical sensor (425 times), and sensitivity (368 times). The network of authors' words and their co-occurrence has been illustrated using VOSviewer software. Each circle in the image represents a key word set of the author. While, the frequency circle is indicated by the number of keywords, and the strength of the co-occurrence is evaluated by different colours for the nodes.The most important keywords in the clusters are listed in the table (3).

Cluster 1 (Red) – Biosensor Devices & Transducers, Keywords include biosensors, field-effect transistors (FET), chemical imaging sensors, PH- sensors, carbon nanotubes, ISFET, extended-gate FET, and ion-sensitive sensors. This cluster mainly focuses on fundamental biosensor architecture, especially the electrical and electrochemical transduction mechanisms. Carbon nanotubes and metal oxides to improve electron transfer(J. Li et al., 2007), Miniaturized sensors like light-addressable potentiometers(Wan et al., 2015), additionally High precision in pH sensing and surface potential monitoring(Wan et al., 2015)

Cluster 2 (Green) – Microfluidics & Nanomaterial Integration
Cluster two Keywords include microfluidics, nanomaterial, nanotoxicity, aptasensors, drug delivery, nano medicine, fluorescence, tissue engineering, and lab-on-a-chip. This cluster mainly emphasizes the synergy of nanotechnology with microfluidics for advanced bio sensing. This cluster emphasizes certain technological trends. Lab-on-a-chip platforms combining fluidics and sensing(Allert et al., 2022), Integration of aptamers for high specificity(Yu et al., 2023), Drug discovery and delivery systems linked with biosensors(Tan et al., 2022).

Cluster 3 (Blue) – Electrochemical Biosensors
Cluster three Keywords include electrochemical sensor, electrochemical biosensor, cyclic voltammetry, amperometric sensor, carbon dots, graphene oxide, MXene. Nanostructured materials are often used in electrochemical detection techniques. Electrochemical Biosensors often used graphene oxide, MXenes, and carbon dots for enhancing conductivity and sensitivity(Reddy et al., 2022), Techniques such as voltammetry Biosensors are used to measure different pulses in the human body(Baluta et al., 2022).

Cluster 4 (Yellow) – Biophysics & Sensitivity Enhancement
Cluster four identified main keywords, molecular biophysics, biomolecules, sensitivity, dielectrics, TFTs (thin-film transistors), tunnelling, logic gates, Nano gap, theme focused on molecular interactions and device sensitivity improvements. Logic gate biosensors for decision-making bio-computation(Baluta et al., 2022) and development of nano-gap electrodes for ultra-sensitive measurements(Baluta et al., 2022).

Top cited documents
The importance of any research publication can be measured by its citation count, which allows us to perceive its importance in the relevant context(Bornmann & Daniel, 2008). Table (4) presents the ten most highly cited papers, both locally and globally, in the domain of Semiconductor-Based Biosensors for Drug Monitoring, covering the period from January 1991 to July 9, 2025. We closely examined global and local citations in articles related to this field. In comparison, Global citations refer to citations that a document receives from various index databases. In contrast, local citation counts only measure the number of citations a document receives from a dataset on various platforms (e.g. Google Scholar). In Table (4) explained top cited documents, Significant advancements in bio sensing and bioengineering have been driven by innovations in materials, nanotechnology, and microfabrication. Early breakthroughs, such as soft lithography, enabled precise patterning of proteins and cells, establishing a foundation for bio interface engineering and tissue applications (Kane et al., 1999). This progress was facilitated by advancements in polymer-based sensing platforms, which utilized both conducting and non-conducting polymers for their adaptability in sensor design.(Adhikari & Majumdar, 2004). Nanomaterial emerged as transformative tools, with quantum dots offering unique optical properties for in vivo molecular and cellular imaging(Smith et al., 2008), while Aptamer provided highly specific and stable recognition elements for the development of biosensors (Song et al., 2008).

In parallel, gold nanoparticles have enhanced electrochemical biosensors by offering superior surface modification and signal amplification(Pingarrón et al., 2008). Graphene has significantly enhanced sensing capabilities due to its remarkable conductivity, sensitivity, and structural properties(Pumera et al., 2010)enhanced by the adaptability of carbon nanotube-based platforms for detecting a range of biomolecules, from neurotransmitters to DNA(Jacobs et al., 2010). In a similar vein, modifications of carbon nanotubes in electro analysis have enhanced biosensor performance across a wide range of applications(Katz & Willner, 2003).More recently, Devices enabled by nanomaterial, such as

graphene field-effect transistor (FET)-based biosensors, have shown exceptional diagnostic potential by facilitating the ultra-rapid detection of SARS-CoV-2 from clinical swab samples(Seo et al., 2020)Together, these studies highlight the shift from micro fabrication-based biomaterial patterning to the cutting-edge realm of nanomaterial-enabled bio sensing and diagnostics. They emphasize how innovations in material science are continually shaping the development of high-performance biosensors and biomedical devices(Sarkar et al., 2014).

DISCUSSION

Figure (3) clearly reveals detailed explanation in this bibliometric analysis, the results are discussed from the keyword co-occurrence and top cited documents. Terms such as "integrated sensors", "enzyme inhibition", "electrophysiology", and "microarrays" appear first. This keywords focus on basic biosensing technologies and biological testing methods. Emergence of "graphene", "quantum dots", "microfluidics", "field-effect transistors", and "gold nanoparticles" reflects the rise of nanotechnology applications in biosensing and diagnostics. although strong bursts for terms like "artificial intelligence", "machine learning", "electrochemical sensors", and "biomarkers" shows a shift towards AI-powered biosensors and smart diagnostic platforms. Large bubbles in graphene and nanomaterial from 2017 to 2019 highlight a massive surge in nanomaterial-based sensors. Artificial Intelligence & Machine Learning keywords are recently emerging terms, indicating a major trend of integrating AI into bio sensing, and a Point-of-Care Testing 2015 to 2023 high number of word counts reflect clinical and real-time health monitoring applications. Nanotechnology, micro electro mechanical systems (MEMS), and biocompatibility extend through decades, showing sustained relevance, and some specific techniques such as formaldehyde detection or enzyme inhibition peak early and then decrease.

This timeline bubble plot Fig (7) clearly illustrates the dynamic evolution of biosensor and nanotechnology research over nearly three decades. Early work laid the technical foundation with integrated sensors and enzyme-based detection. The middle-phase was characterized by the nanotechnology revolution (Graphene, quantum dots, MEMS). Current and future focus lies in AI-driven, bio-compatible, and electro chemical sensing platforms for healthcare, personalized medicine, and environmental monitoring The figure (8) illustrates the relationship between countries (AU_CO), journals (SO), and universities/institutions (AU_UN) in the field of biosensors and related research. Major contributing countries such as China and the United States dominate, followed by Korea, Japan, Germany, and India. The major publishing journals are Biosensors & Bioelectronics, Sensors and Actuators B: Chemical, IEEE Sensors Journal, and Analytica Simica Acta. These serve as major hubs for international research convergence. The leading institutions are the Chinese Academy of Sciences, the University of California System, and the Indian Institute of Technology, Stanford University, and Zhejiang University. According to the results, the top ten most cited papers were published in the early period and focused on Advanced Materials for Bio sensing, Transduction Mechanisms, and Integration of Bimolecular Recognition, Applications in Clinical Diagnostics, Miniaturization and Scalability. The most cited papers were published in journals, such as PubMed and ACSNano. Findings of the top-cited papers. However, the findings of these top-cited papers suggest that nanomaterial, such as graphene, carbon nanotubes (CNTs), gold nanoparticles, MoS_2, and quantum dots, are gaining importance in improving biosensor performance.Furthermore, our findings indicate that developed nations engage in a greater volume of research activities compared to developing and underdeveloped nations. Despite the larger populations in developing countries, their research contributions remain underrepresented.

Strength and Limitation

Our study analyses and describes a significant amount of data obtained from a reputable database. Our study provides an in-depth description of key authors, countries with the most publications, and institutions of importance through bibliographic analysis. Our entire study has inherent limitations to bibliometric studies. According to(Hou & Wang, 2021)state that bibliometric analysis can be helpful in clearly explaining the entire research progress in a research field. However, the in-depth information and findings related to a research cannot be replaced, we

encourage researchers to conduct bibliometric analysis as a result. Furthermore, when data is retrieved from the database, unnecessary information is automatically added, which the author must remove before bibliometric analysis. For example, the data may include an additional year than the measured year, which the author should avoid. Furthermore, this study was conducted on only 7863 papers, which is sufficient to describe semiconductor chip-based biosensors for medical devices in the scientific world, and the most cited paper belongs to this field, so there is no need to depend on any other field. The number of journals and authors required for analysis was sufficient.

Future Directions

According to the bibliometric key results, to further analyse future research trends in this field, future research on biosensors should prioritize interdisciplinary integration with artificial intelligence, nanomaterials, and flexible electronics to improve sensitivity and portability. The application of biosensors is scalable, and therefore expected to dominate the next decade.

- The analysis revealed strong research growth in biosensors in the medical field, with China and the United States leading the way in publications, while collaboration with developing countries remains limited, where research should focus.
- Keyword analysis suggests a potential area for interdisciplinary research that integrates real-time disease diagnosis and predictive health monitoring capabilities.
- 2D materials beyond graphene (e.g., MXenes, MoS_2) are promising nanomaterials for ultrasensitive biosensors. They are environmentally friendly and adaptable biosensors.

A keyword search can be modified to include additional words relevant to the field, which can provide a deeper understanding of the research field and conduct a literature review and meta-analysis in the field.Reviews provide additional insights into the antecedents and consequences of the field, so empirical studies and reviews can describe the in-depth content of this research field(Ketcham & Crawford, 2007), explored can be connections between various medical financial organization systems and creative entrepreneurs, the social marketing of medical tools, and the rapid advancement of the digital community.

FINDINGS AND CONCLUSION

This study is unique in that it examines the role of semiconductors in biology. The study is based on a database that is widely used by researchers worldwide. The results of the study reveal several conclusions. Biosensors have become important in the medical field due to their excellent sensitivity, stability, reproducibility, and immediate response time, and this study concludes that the growth of biosensors research output is rapid. According to the results, the biotechnology sector has developed well in the medical field and its development has been well integrated with various nanotechnology innovations. Section 3.2: research publications from 2022 to 2024 have shown significant improvement over other years. Section 3.3: the biosensors and bioelectronics journal and the Sensors and Actuators B-Chemical journal have been identified as key sources Section 3.4: China, the United States, India, and Korea are the major contributing countries, while the Chinese Academy of Sciences, the University of California system, and the Indian IITs are the major research institutions Section 3.5: Zhang Y, Wang J, and Kumar S are the main contributors to this field of research. The VOSviewer tool plays a role in many areas of research, including keyword analysis and cross-country collaboration. Keyword analysis has identified the most common areas of application for biosensors in the medical sector. Accordingly, biosensors used to measure fat level, cancer, breast cancer and COVID-19 pandemic are in high demand. The study highlights the growth of nanotechnology in biomedical devices. The development of 2D materials like Graphene, the growth of keywords like Graphene oxide, gold nanoparticles, Quantum dots and carbon nanotubes highlights the growth of nanotechnology. Semiconductor technology has revolutionized biosensors and is amazing. This makes it easier for experts to directly and electronically measure biological interactions. Semiconductor chips are used in key applications beyond CMOS

technology, increasing the demand for more powerful semiconductors, which medical research institutions, financial institutions, and policymakers must contribute to accordingly.

ACKNOWLEDGEMENT

We thank all the authors whose work was used as a reference for this study. We would like to express our gratitude for the personal motivation, valuable guidance, ongoing supervision, and constructive criticism from the topic's selection to its completion.

Funding

The work was no funding support

Conflict of interests

The authors declare no Conflict interests.

ABSTRACT

Transient acantholytic dermatosis, commonly known as Grover's disease, is a pruritic skin disorder characterized by focal acantholysis and erythematous papular eruptions, primarily affecting the trunk. Conventional therapies such as topical corticosteroids and antihistamines provide symptomatic relief but are often associated with recurrence and potential adverse effects upon prolonged use. Therefore, there is a growing need for safer and more effective alternative therapeutic approaches. The present study focuses on the formulation and evaluation of a herbal syrup containing the natural root exudate (Udumbarajal) of *Ficusracemosa* for the supportive management of transient acantholytic dermatosis. The root exudate is a naturally occurring aqueous secretion obtained directly from the roots without solvent extraction and is traditionally used in Ayurvedic medicine for the treatment of inflammatory and skin disorders. It contains various bioactive constituents such as flavonoids, tannins, and phenolic compounds, which possess anti-inflammatory, antioxidant, and wound-healing properties. The herbal syrup was formulated using the root exudate along with suitable excipients including sweetening agents (honey/sorbitol), glycerine as a humectant, citric acid as a stabilizer, sodium benzoate as a preservative, and purified water as the vehicle. The prepared formulation was evaluated for organoleptic properties, physicochemical parameters such as pH, viscosity, and density, as well as stability and microbial safety. The formulation exhibited acceptable organoleptic characteristics with good palatability and stability. The physicochemical parameters were found to be within acceptable limits for oral administration, and microbial evaluation confirmed the safety of the formulation. The presence of bioactive phytoconstituents suggests its potential role in reducing inflammation and promoting skin healing. In conclusion, the

developed herbal syrup containing natural root exudate of *Ficus racemosa* shows promising potential as a safe and effective supportive therapy for transient acantholytic dermatosis. However, further clinical studies are required to validate its therapeutic efficacy and establish its role in dermatological treatment.

Keywords: *Ficus racemosa* Root exudate, Udumbarajal, Transient acantholytic dermatosis, Grover's disease, Herbal syrup, Formulation and evaluation, Anti-inflammatory, Phytochemicals, Dermatological therapy.

INTRODUCTION

Transient acantholytic dermatosis, commonly known as Grover's disease, is an acquired pruritic dermatological disorder characterized by focal acantholysis and dyskeratosis within the epidermis. The condition was first described by Ralph W. Grover in 1970 and predominantly affects middle-aged to elderly individuals, with a higher incidence reported in males. Clinically, it presents as erythematous papules or papulovesicular eruptions, mainly distributed over the chest and back, and is often associated with intense itching that significantly impacts the patient's quality of life (Grover, 1970; Parsons, 1996). The exact etiology of transient acantholytic dermatosis remains unclear; however, several predisposing and triggering factors have been identified. These include excessive heat, sweating, prolonged bed rest, xerosis, ultraviolet radiation, and certain medications. Histopathological examination reveals focal acantholysis resembling patterns observed in other dermatological conditions such as pemphigus vulgaris and Darier's disease. Although the disease is generally benign and self-limiting, its recurrent nature and persistent pruritus necessitate effective management strategies (Weedon, 2010; James et al., 2016).

Current treatment approaches primarily focus on symptomatic relief and include the use of topical corticosteroids, oral antihistamines, retinoids, and phototherapy. While these therapies may alleviate symptoms temporarily, they are often associated with limitations such as recurrence, adverse effects on prolonged use, and variability in patient response. Long-term use of corticosteroids, for instance, may lead to skin atrophy, irritation, and systemic side effects. These limitations highlight the need for safer, more effective, and sustainable alternative therapies (Habif, 2015). In recent years, there has been increasing interest in herbal medicines due to their favorable safety profile, cost-effectiveness, and long history of traditional use. Medicinal plants are rich sources of bioactive compounds that exhibit diverse pharmacological activities. Among these, *Ficus racemosa* commonly known as cluster fig or Udumbara, is a well-known medicinal plant belonging to the Moraceae family. It is widely distributed across India and has been extensively used in traditional systems of medicine such as Ayurveda for the treatment of various ailments, including inflammatory conditions, wounds, and skin disorders (Kirtikar & Basu, 2006).

A unique feature of *Ficus racemosa* is the natural aqueous fluid that exudes from its roots, commonly referred to as Udumbarajal. This root exudate is traditionally collected and used directly solvent extraction,preserving its natural composition of water-soluble phytoconstituents. Unlike conventional extraction processes, the use of root exudate ensures minimal processing and may enhance the bioavailability of active compounds. Traditional knowledge suggests its effectiveness in managing skin-related conditions and inflammatory disorders, making it a promising candidate for further scientific investigation (Khandelwal, 2008; Harborne, 1998). Phytochemical studies have revealed that *Ficus racemosa* contains a wide range of bioactive constituents such as flavonoids, tannins, phenolic compounds, glycosides, and triterpenoids. These compounds are known to possess significant anti-inflammatory, antioxidant, antimicrobial, and wound-healing properties. The antioxidant activity helps in scavenging free radicals, thereby reducing oxidative stress, while the anti-inflammatory properties contribute to the reduction of skin inflammation and irritation. Additionally, antimicrobial activity helps prevent secondary infections, which are common in dermatological conditions (Joseph & Raj, 2011; Sharma et al., 2012). The pharmacological properties of *Ficus racemosa* are particularly relevant in the management of transient acantholytic dermatosis, where inflammation, oxidative stress, and disruption of epidermal integrity play a key role in disease pathogenesis. By targeting these

underlying mechanisms, the plant may provide a holistic approach to managing the condition. Moreover, its traditional usage further supports its safety and therapeutic potential.

Oral herbal formulations such as syrups offer several advantages, including ease of administration, improved patient compliance, and better palatability. Syrups provide a stable medium for delivering aqueous herbal preparations and allow uniform distribution of active constituents. The use of natural sweetening agents such as honey not only enhances taste but also contributes additional antimicrobial and soothing effects. Furthermore, excipients such as glycerin improve viscosity and mouthfeel, while preservatives ensure microbial stability of the formulation (Allen, 2013; Aulton, 2018). Despite the extensive pharmacological potential and traditional use of *Ficus racemosa* there is a lack of scientific research focusing on the formulation of its root exudate into standardized pharmaceutical dosage forms, particularly for dermatological conditions such as transient acantholytic dermatosis. Most studies have focused on extracts or isolated compounds rather than natural exudates and patient-friendly dosage forms. This represents a significant research gap.

Therefore, the present study aims to formulate and evaluate a herbal syrup containing the natural root exudate of *Ficus racemosa* for the supportive management of transient acantholytic dermatosis. By integrating traditional knowledge with modern pharmaceutical techniques, this study seeks to develop a safe, effective, and standardized herbal formulation for dermatological use.

AIM:To formulate and evaluate a herbal syrup containing the natural root exudate (Udumbarajal) of Ficusracemosa for the supportive management of Transient acantholytic dermatosis.

OBJECTIVES

- To collect and authenticate the plant material of *Ficus racemosa.*
- To collect the natural root exudate (Udumbarajal) from the roots of *Ficus racemosa* using an appropriate method.
- To formulate a stable and palatable herbal syrup using the collected root exudate and suitable excipients such as sweetening agents, humectants, stabilizers, and preservatives.
- To evaluate the organoleptic properties of the prepared formulation, including color, odor, taste, and appearance.
- To determine the physicochemical parameters of the formulation such as pH, viscosity, density, and clarity.
- To perform phytochemical screening of the root exudate-based formulation.
- To conduct stability studies under different storage conditions to assess the shelf-life of the formulation.
- To carry out microbial limit tests to ensure the safety and quality of the formulation.
- To assess the potential therapeutic relevance of the formulation based on its anti-inflammatory and antioxidant properties.

MATERIALS AND METHODS

Collection and Authentication of Plant Material

Fresh roots of *Ficus racemosa* were selected from healthy, mature plants growing in a natural habitat. The plant was identified and authenticated by a qualified botanist based on standard morphological characteristics. A voucher specimen was prepared and preserved in the herbarium for future reference. The roots were carefully exposed by removing surrounding soil, ensuring minimal damage to the plant system. Proper authentication is essential to ensure reproducibility and validity of the research (Kokate et al., 2010; Evans, 2009).

Collection of Root Exudate (Udumbara Jal):

The study utilized the natural aqueous root exudate (Udumbarajal) instead of solvent-based extraction. The exposed roots were gently cleaned, and a small incision was made on the surface using a sterile blade. The naturally oozing fluid was collected directly into sterile containers without applying external pressure to maintain its natural

composition.The collected exudate was immediately filtered through muslin cloth to remove coarse impurities, followed by filtration using Whatman filter paper for clarification. The filtrate was stored in sterile, amber-colored containers at refrigerated temperature (2–8°C) to prevent microbial contamination and degradation of bioactive constituents. This method preserves the natural aqueous phytoconstituents present in the plant (Khandelwal, 2008; Harborne, 1998).

Materials Used in Formulation

The formulation included the collected root exudate of *Ficus racemosa* as the active ingredient. Excipients used were honey or sorbitol as sweetening agents, glycerin as a humectant and viscosity enhancer, citric acid as a pH adjuster and stabilizer, sodium benzoate as a preservative, and purified water as the vehicle. All chemicals and reagents used were of analytical grade and complied with pharmacopeial standards (Indian Pharmacopoeia, 2022).

Formulation of Herbal Syrup

The herbal syrup was prepared using standard pharmaceutics techniques. Initially, the required quantity of sweetening agent (honey/sorbitol) was dissolved in a portion of purified water with gentle heating. Glycerin was added to improve viscosity and mouthfeel. Citric acid was incorporated to maintain an appropriate pH and enhance flavor stability. Sodium benzoate was dissolved separately and added as a preservative.The filtered root exudate of *Ficus racemosa* was then slowly added to the syrup base with continuous stirring to ensure uniform mixing. The final volume was adjusted to 100 ml using purified water. The prepared syrup was filtered, if necessary, and transferred into clean, dry, amber-colored bottles, which were properly labeled and stored at room temperature (Allen, 2013; Aulton, 2018).

Evaluation of Organoleptic Properties

The prepared formulation was evaluated for organoleptic characteristics including color, odor, taste, and overall appearance. These parameters were assessed visually and by sensory evaluation. The formulation was considered acceptable if it exhibited a pleasant taste, characteristic odor, and uniform appearance without turbidity or precipitation (Lachman et al., 2013).

Physicochemical Evaluation: The formulated syrup was subjected to physicochemical analysis to ensure quality and consistency. The pH was determined using a calibrated digital pH meter and maintained within an acceptable range (4–7) suitable for oral administration. Viscosity was measured using a Brookfield viscometer to evaluate flow properties. Density and specific gravity were determined using a pycnometer. Clarity, homogeneity, and absence of particulate matter were also assessed visually. These parameters are essential for ensuring stability and uniform dosing (Indian Pharmacopoeia, 2022; Aulton, 2018).

Phytochemical Screening

Preliminary phytochemical screening of the root exudate-based formulation was carried out to identify the presence of major bioactive constituents such as flavonoids, tannins, phenolic compounds, glycosides, and alkaloids using standard qualitative tests. These phytoconstituents are responsible for the therapeutic activity of the formulation (Harborne, 1998).

Stability Studies

Stability studies were conducted according to ICH guidelines to evaluate the effect of environmental conditions on the formulation. The syrup was stored under different conditions, including room temperature and accelerated conditions (40°C ± 2°C and 75% relative humidity). Samples were analyzed at regular intervals for changes in color, odor, pH, viscosity, and overall appearance. Any signs of instability such as precipitation or phase separation were recorded (ICH Q1A(R2), 2003).

Microbial Limit Test

Microbial evaluation was performed using standard plate count methods to determine the total viable microbial load. The formulation was tested for the presence of bacteria and fungi to ensure safety. The effectiveness of sodium benzoate as a preservative was confirmed by maintaining microbial counts within acceptable pharmacopeial limits. The absence of pathogenic microorganisms indicated the microbiological safety of the formulation (Indian Pharmacopoeia, 2022).

DISCUSSION

The present study was undertaken to formulate and evaluate a herbal syrup containing the natural root exudate (Udumbarajal) of Ficusracemosa for the supportive management of Transient acantholytic dermatosis. The discussion integrates the findings obtained from formulation development, physicochemical evaluation, phytochemical screening, stability studies, and microbial analysis to justify the suitability and potential efficacy of the developed formulation. The use of natural root exudate instead of conventional extracts represents a novel approach in herbal formulation. Unlike solvent-based extraction, the exudate is a naturally occurring aqueous fluid that contains water-soluble phytoconstituents in their native form. This minimizes processing steps and may help preserve the biological activity and bioavailability of active compounds. From a pharmaceutical perspective, this approach aligns well with traditional Ayurvedic practices while maintaining scientific validity.

The organoleptic evaluation of the formulation revealed a brownish color, pleasant odor, and sweet taste with a mild herbal aftertaste. These characteristics are important for oral dosage forms, as patient compliance is strongly influenced by taste and appearance. The use of honey or sorbitol as a sweetening agent not only improved palatability but may also contribute additional antimicrobial and soothing properties, thereby enhancing the therapeutic value of the formulation. The parameters physicochemical obtained in the study were found to be within acceptable limits for oral syrups. The pH of the formulation (around 5.2) is suitable for oral administration and ensures stability of the active constituents. The viscosity was adequate to provide a smooth flow and ease of dosing without being too thick or too thin. Density and specific gravity values indicated uniformity in formulation, while clarity confirmed the absence of particulate matter or instability. These results demonstrate that the formulation meets standard pharmaceutics requirements and is suitable for patient use.

The phytochemical screening confirmed the presence of key bioactive constituents such as flavonoids, tannins, phenolic compounds, glycosides, and terpenoids. These compounds are well known for their anti-inflammatory, antioxidant, antimicrobial, and wound-healing properties. Flavonoids and phenolic compounds play a crucial role in scavenging free radicals and reducing oxidative stress, which is a contributing factor in many skin disorders. Tannins provide astringent and antimicrobial effects, while terpenoids and glycosides contribute to anti-inflammatory and tissue repair mechanisms. The presence of these constituents supports the therapeutic potential of the formulation in managing inflammatory skin conditions. The stability studies indicated that the formulation remained stable under both room temperature and accelerated conditions, with no significant changes in pH, color, or appearance. A slight variation in viscosity under accelerated conditions was observed but remained within acceptable limits. The absence of precipitation or phase separation suggests good physical stability of the formulation. These findings confirm that the developed syrup has an acceptable shelf-life and can maintain its quality during storage.

The microbial evaluation demonstrated that the formulation complies with pharmacopeial limits for microbial load. The absence of pathogenic microorganisms and acceptable total viable count indicate that the formulation is microbiologically safe. The inclusion of sodium benzoate as a preservative played a significant role in preventing microbial growth and ensuring product safety. From a therapeutic perspective, the pharmacological activities of *Ficus racemosa* are highly relevant to the management of transient acantholytic dermatosis. The condition involves inflammation, disruption of epidermal integrity, and possible secondary infections. The anti-inflammatory properties of the plant help reduce skin irritation and itching, while antioxidant activity minimizes oxidative damage to skin cells. Additionally, antimicrobial properties help prevent secondary infections, which can worsen the condition. Although the formulation is intended as a supportive therapy, its multi-target mechanism of action makes it a promising alternative to conventional treatments.

Despite these positive findings, certain limitations should be acknowledged. The study is primarily based on formulation and in-vitro evaluation, and does not include clinical trials to directly assess therapeutic efficacy in

patients. Therefore, further studies, including in-vivo and clinical evaluations, are necessary to validate the effectiveness of the formulation in real-world conditions.

CONCLUSION

The present study successfully focused on the formulation and evaluation of a herbal syrup containing the natural root exudate (Udumbarajal) of Ficusracemosa for the supportive management of Transient acantholytic dermatosis. The use of root exudate instead of conventional extracts represents a novel and scientifically relevant approach, as it preserves the natural composition of water-soluble phytoconstituents while aligning with traditional medicinal practices. The developed formulation exhibited acceptable organoleptic properties, including pleasant taste, characteristic odor, and uniform appearance, which are essential for patient compliance. The physicochemical evaluation confirmed that parameters such as pH, viscosity, density, and clarity were within acceptable limits, indicating that the formulation is suitable for oral administration and meets standard pharmaceutical requirements.
Phytochemical screening revealed the presence of important bioactive compounds such as flavonoids, tannins, phenolic compounds, and terpenoids. These constituents are known for their anti-inflammatory, antioxidant, antimicrobial, and wound-healing activities, which are highly relevant in managing inflammatory skin conditions. The stability studies demonstrated that the formulation remained stable under different storage conditions, with no significant changes in physical or chemical properties. Additionally, microbial evaluation confirmed that the formulation is safe and free from harmful microorganisms.

Overall, the results indicate that the developed herbal syrup is stable, safe, and pharmaceutically acceptable, with promising therapeutic potential. Although the study provides strong preliminary evidence supporting its use, further *in-vivo* and clinical studies are necessary to establish its efficacy and confirm its role as an alternative or adjunct therapy in dermatological treatment.

Table 1. Plant Profile

Parameter	Details
Botanical Name	*Ficus racemosa*
Family	Moraceae
Common Name	Cluster fig, Indian fig tree
Vernacular Names	Hindi: Gular; Marathi: Umbar; Sanskrit: Udumbara
Plant Type	Medium to large deciduous tree
Height	Approximately 15–20 meters
Geographical Distribution	Widely distributed in India, Sri Lanka, Nepal, and Southeast Asia; commonly found in tropical and subtropical regions
Habitat	Forest areas, riverbanks, rural and moist regions
Morphology	Bark: smooth, grayish-brown; Leaves: simple, ovate; Fruits: clustered figs on trunk; Roots: well-developed
Parts Used	Bark, fruits, leaves, roots (especially root exudate)
Special Feature	Produces natural aqueous root exudate (Udumbarajal)
Phytochemical Constituents	Flavonoids, tannins, phenolic compounds, glycosides, triterpenoids
Pharmacological Activities	Anti-inflammatory, antioxidant, antimicrobial, wound healing, hepatoprotective
Traditional Uses	Used in Ayurveda for skin diseases, wound healing, diarrhea, inflammation

Table 2. Formulation

Sr. No.	Ingredients	Quantity (for 100 ml)	Function
1	Root exudate (*Ficus racemosa*)	20 ml	Active ingredient
2	Sorbitol	66.7 g	Sweetening agent
3	Glycerin	10 ml	Humectant, viscosity enhancer
4	Citric acid	0.5 g	pH adjuster, stabilizer
5	Sodium benzoate	0.2 g	Preservative
6	Beet root	q. S	Coloring Agent
7	Peppermint oil	q.s.	Flavoring agent
7	Purified water	q.s. to 100 ml	Vehicle

Table 3. Phytochemical screening of herbal syrup:

Sr. No.	Phytochemical Test	Test Performed	Result	Inference
1	Alkaloids	Mayer's / Dragendorff's test	+ (Present)	Indicates presence of nitrogenous compounds with potential pharmacological activity
2	Flavonoids	Shinoda test	+ (Present)	Confirms antioxidant and anti-inflammatory properties
3	Tannins	Ferric chloride test	+ (Present)	Suggests astringent and antimicrobial activity
4	Phenolic compounds	Ferric chloride test	+ (Present)	Indicates strong antioxidant potential
5	Glycosides	Keller–Killiani test	+ (Present)	Suggests possible cardioprotective and therapeutic effects
6	Saponins	Foam test	+ (Present)	Indicates surfactant and immune-modulating properties
7	Terpenoids	Salkowski test	+ (Present)	Confirms anti-inflammatory and wound-healing activity
8	Steroids	Liebermann–Burchard test	+ (Present)	Indicates presence of phytosterols with anti-inflammatory effects
9	Proteins	Biuret test	– (Absent)	No significant protein content detected
10	Carbohydrates	Molisch's test	+ (Present)	Confirms presence of sugars contributing to energy and formulation stability

Table 4. Organoleptic Evaluation

Parameter	Observation	Parameter
Color	Brownish	Color
Odor	Characteristic, pleasant	Odor
Taste	Sweet with mild herbal aftertaste	Taste
Appearance	Clear and free from particulate matter	Appearance

Table 5.Physicochemical Evaluation

Parameter	Result	Standard Range
pH	5.2 ± 0.1	4 – 7
Viscosity	1200 ± 50 cps	Suitable for syrup
Density	1.15 g/ml	~1 – 1.3 g/ml
Specific Gravity	1.12	Close to standard
Clarity	Clear	Clear

Table 6. Phytochemical Screening Results

Constituent	Result
Flavonoids	Present (+)
Tannins	Present (+)
Phenolic compounds	Present (+)
Glycosides	Present (+)
Saponins	Present (+)
Terpenoids	Present (+)
Steroids	Present (+)

Proteins	Absent (–)
Carbohydrates	Present (+)

Table 7. Stability Study

Condition	Duration	Observation
Room temperature	30 days	No significant change
Accelerated (40°C ± 2°C)	30 days	Slight change in viscosity, acceptable
pH variation	—	No significant change
Appearance	—	No precipitation or color change

ABSTRACT

Bamboo rice is a nutrient-rich grain traditionally consumed by indigenous communities and has emerging potential in gluten-free food applications. This study investigated the formulation and quality evaluation of gluten-free brownies prepared using bamboo rice flour as a complete replacement for wheat flour. The developed product was compared with a conventional brownie for sensory attributes, nutritional composition, functional properties, antioxidant activity, gluten content, microbial safety, and shelf stability. Sensory analysis indicated significantly higher overall acceptability of bamboo rice brownies, with favourable scores for taste, texture, and appearance. Nutritional assessment demonstrated increased protein, dietary fibre, and mineral content, along with reduced fat and gluten levels. Improved water absorption and moisture retention contributed to enhanced textural quality. Microbiological analysis confirmed product safety throughout the storage period. The results demonstrate that bamboo rice flour is a viable ingredient for developing nutritionally superior gluten-free brownies, offering a functional and sustainable alternative for health-conscious consumers and individuals with gluten intolerance.

Keywords: Bamboo rice, Gluten-free brownie, Sensory evaluation, Nutritional quality, Antioxidant activity, Shelf-life stability, Phytochemical content, Celiac-friendly foods, Indigenous resources.

INTRODUCTION

The prevalence of celiac disease, estimated at approximately 1% of the global population, necessitates strict lifelong adherence to gluten-free diets to prevent intestinal mucosal damage and associated nutritional deficiencies. However, conventional gluten-free bakery products often exhibit inferior nutritional quality and compromised sensory attributes when compared to their wheat-based counterparts. Simultaneously, India's organized bakery sector, with an annual turnover exceeding ₹3,000 crores, is witnessing growing consumer demand for functional and health-oriented foods aimed at managing diet-related non-communicable diseases such as obesity and diabetes mellitus. Bamboo rice (Bambusa arundinacea), the edible seed obtained during the gregarious flowering cycle of bamboo occurring once every 20–50 years, has gained attention as a nutritionally superior and sustainable indigenous cereal alternative. Bamboo rice exhibits a favourable proximate composition, with high protein (22.45 g/100 g), dietary fibre (13.36 g/100 g), appreciable levels of calcium (24.84 mg/100 g) and phosphorus (96.91 mg/100 g), a low glycaemic index, and significant antioxidant activity. Utilization of bamboo rice not only offers potential for gluten-free food product development but also contributes to sustainable resource use and livelihood support for tribal communities.

Brownies, a popular bakery product, are traditionally formulated using refined wheat flour and are characterized by high fat and sugar content, which may contribute to metabolic disorders when consumed frequently. Reformulating brownies using nutrient-dense, gluten-free ingredients such as bamboo rice flour may enhance their nutritional profile while catering to consumers with gluten intolerance and those seeking healthier bakery alternatives. In this context, the present investigation was undertaken to develop gluten-free brownies through complete substitution of wheat flour with bamboo rice flour and to evaluate their suitability as a functional bakery product. The study focused on assessing the sensory acceptability using a nine-point hedonic scale, along with detailed evaluation of physical characteristics, proximate composition, phytochemical profile, gluten content, microbiological quality, and accelerated shelf-life under controlled conditions, with statistical significance determined at $p < 0.05$.

MATERIALS AND METHODOLOGY

Materials

Bamboo rice (Bambusa arundinacea) procured from verified tribal sources (Kerala); processed into flour (cleaned, sun-dried, dehusked, milled 100 mesh). Other ingredients from Chennai markets: wheat flour (control), butter (75g), dark chocolate (220g), castor sugar (100g), palm sugar (80g), cocoa powder (30g), corn flour (15g), curd (25g), baking powder (5g), baking soda (3g), coffee powder (10g).

Electronic balance, mixer, oven (170°C), vernier caliper, colorimeter, Soxhlet apparatus.

Equipment: Electronic balance, mixer, oven (170°C), vernier caliper, colorimeter, Soxhlet apparatus.

Methodology

Preparation of Brownies:

- Butter (75 g) and dark chocolate (220 g) were melted in a double boiler.
- Dry ingredients were sifted: flour (170 g; wheat flour for control, bamboo rice flour for treatment), cocoa powder (30 g), corn flour (15 g), baking powder (5 g), baking soda (3 g), instant coffee powder (10 g).
- Sugars (castor sugar 100 g, palm sugar 80 g) were creamed with curd (25 g), then folded into chocolate mixture.
- Sifted dry ingredients were gradually incorporated to form batter. Batter was transferred to parchment-lined baking tray.
- Baked in preheated oven at 170°C for 20-25 minutes (toothpick test: clean center). Brownies cooled 10-15 minutes in tray.

Analysis

Organoleptic evaluation: Nine-point hedonic scale (n=30 semi-trained panelists); parameters: appearance, color, taste, texture, flavor, overall acceptability. One-way analysis of variance (ANOVA).

Proximate composition: Energy (factorial calculation); protein (Lowry method); carbohydrates (Anthrone method); fat, crude fibre (Soxhlet extraction); ash (muffle furnace); moisture (gravimetric); calcium (EDTA complexometric titration); phosphorus (vanadomolybdate spectrophotometry) - all AOAC methods.

Phytochemical screening: Qualitative tests for flavonoids, alkaloids, tannins, terpenoids, saponins, steroids; total phenolics (Folin-Ciocalteu); total flavonoids (aluminium chloride); DPPH radical scavenging activity.

Gluten quantification: Enzyme-linked immunosorbent assay (ELISA; threshold <20 ppm).

Microbiological analysis: Total bacterial count, total yeast and mould count (pour plate method; CFU/g).

Shelf-life study: Accelerated shelf-life testing (40°C, 75% RH, 15 days); water activity (Aw), microbial enumeration.

Statistical analysis: SPSS version 25.0; triplicate determinations presented as mean ± standard deviation (SD). One-way ANOVA .

RESULTS AND DISCUSSION

The present investigation examined the feasibility of producing a gluten-free brownie using bamboo rice flour as a total replacement for wheat flour and evaluated its quality attributes in comparison with a conventional formulation. The assessment included sensory performance, physical and functional characteristics, nutritional quality, antioxidant properties, gluten content, microbial safety, storage stability, and economic considerations. All analyses were conducted under controlled conditions, and statistical significance was determined at $p< 0.05$.

Organoleptic Evaluation

Sensory analysis indicated that substitution of wheat flour with bamboo rice flour significantly influenced most sensory parameters of the brownie. One-way analysis of variance (Table 3) revealed significant differences ($p< 0.05$) between the control and bamboo rice brownies with respect to appearance, taste, texture, flavour, and overall acceptability, whereas colour did not show a statistically significant variation. The favourable sensory response observed for the bamboo rice brownie may be attributed to its compact crumb structure, improved mouth feel, and characteristic flavour imparted by bamboo rice. The absence of a significant difference in colour suggests that the darker shade associated with bamboo rice flour did not adversely affect consumer perception. These findings demonstrate that bamboo rice flour can be successfully incorporated into brownie formulations without compromising sensory quality.

Nutritional Profile

The replacement of wheat flour with bamboo rice flour resulted in a substantial enhancement of the nutritional profile of the brownie (Table 4). The bamboo rice brownie demonstrated increased protein and dietary fibre contents along with improved mineral composition, notably calcium and phosphorus. Additionally, the reduction in fat and moisture content contributes to a more balanced macronutrient profile and improved shelf stability. These nutritional improvements highlight the suitability of bamboo rice flour as a value-added ingredient for the development of gluten-free bakery products with enhanced health attributes.

Antioxidant Capacity and Bioactive Components

The bamboo rice brownie exhibited superior antioxidant potential compared to the control, reflected by higher levels of phenolic and flavonoid compounds and increased radical scavenging activity. The presence of these bioactive constituents suggests that the product may offer protective health benefits beyond basic nutrition, supporting its classification as a functional food.

Gluten Content and Microbial Quality

Gluten analysis confirmed that the bamboo rice brownie contained gluten levels well below the permissible limit for gluten-free foods, making it appropriate for individuals with celiac disease and gluten sensitivity. Microbiological evaluation showed no detectable bacterial, yeast, or mould growth during the storage period, indicating satisfactory microbial quality. The combined effects of reduced moisture content and naturally occurring bioactive compounds may have contributed to the observed microbial stability.

Economic Evaluation

Although the production cost of the bamboo rice brownie was marginally higher than that of the conventional wheat-based brownie, the enhanced nutritional quality, gluten-free status, and functional attributes justify the additional cost. This supports the potential feasibility of bamboo rice brownies for specialised and health-oriented consumer markets.

CONCLUSION

The present investigation confirms that bamboo rice flour can be effectively employed as a complete substitute for wheat flour in the formulation of gluten-free brownies with enhanced quality attributes. The developed product demonstrated superior sensory performance, particularly in terms of taste, texture, and overall acceptability, indicating strong consumer appeal. Nutritional evaluation revealed marked improvements in protein and dietary fibre content, along with increased antioxidant potential and reduced gluten levels, supporting its suitability for individuals with gluten intolerance. Functional assessment further showed favourable hydration and moisture-retention properties, contributing to desirable textural characteristics. Microbiological analysis confirmed product safety and stability during storage, while shelf-life performance remained satisfactory under tested conditions. Although production costs were marginally higher, the nutritional advantages and functional benefits outweigh the economic constraints. Overall, this study highlights bamboo rice as a nutritionally valuable and sustainable cereal alternative with considerable potential in the development of functional and specialty bakery products, providing a sound foundation for future product optimisation and commercial scale-up.

ABSTRACT

Obesity can be considered one of the most common health issues prevalent across the globe, being linked to various conditions, such as hypertension, diabetes mellitus, chronic kidney disease, nonalcoholic fatty liver disease, and hyperlipidemia. In recent years, medicinal plants have been increasingly researched in order to find an effective solution for treating the condition due to their positive pharmacological properties and fewer side effects. This research paper aims to explore phytochemical analysis and anti-obesity activity of hydroalcoholic seed extract of *Zanthoxylum armatum. Zanthoxylum armatum* seeds were harvested from Sikkim and extracted using 70% hydroethanolic solvent via maceration method. It was established that the seeds contain alkaloids, carbohydrates, flavonoids, tannins, saponins, and polyphenols. The anti-obesity activity of *Zanthoxylum armatum* seeds was estimated based on free fatty acids content in chicken blood serum, measured using titration procedure, with a standard substance Chitosan used as a comparative sample. Two doses of the extract, 250 mg/kg and 500 mg/kg, were used during the experiment. The yield of the extract obtained through maceration was found to be 5.85%. The results of the anti-obesity study revealed the FFA values for the control group, standard group, 250 mg/kg, and 500 mg/kg groups as 143, 118, 135, and 131.5 mmol/L, respectively. It can be observed from

the results that both dosages of the plant extract exhibit anti-obesity activity as they have shown decreased FFA concentration as compared to the control group. These effects can be attributed to the presence of bioactive phytochemicals like flavonoids, alkaloids, polyphenols, and saponins that regulate lipid metabolism. The above results prove that the hydro-alcoholic seed extract of the plant *Zanthoxylum armatum* exhibits anti-obesity properties and can prove to be effective in the treatment of obesity.

Keywords: Obesity, *Zanthoxylum armatum*, Anti-obesity activity, Phytochemical screening, Free fatty acids (FFA)

INTRODUCTION

Obesity and corresponding ailments have become serious health issues and currently becoming the sixth most prevalent major contributor of fatalities worldwide. The World Health Organization (WHO) defines obesity as "abnormal or excessive fat accumulation that may impair health," emphasizing that "an energy deficit between calories consumed and calories expended is the underlying cause of obesity and overweight [1]. Numerous illnesses and ailments that are associated with higher mortality rates are more likely to occur in people who are obese. These include nonalcoholic fatty liver disease (NAFLD), cardiovascular disorders (CVD), metabolic disorder (MetS), chronic renal disease (CKD), hyperlipidemia, hypertension, depression, obstructive breathing while sleeping, osteoarthritis, and some instances of malignancies [2,3]. Visceral and subcutaneous fats are the two categories of fat. Visceral fat is defined as the fat that is built up over visceral organs, including the kidney, belly, liver, intestines, heart, and pancreas. Because studies have shown that visceral fat has an important effect on our hormone activity, leading to insulin resistance and metabolic syndrome, it is also known as "active fat [4]. Hormonal activity impacts hunger, body fat distribution, and metabolism. In addition, subcutaneous fat, which is felt under the arms and legs, is the type of fat that is beneath the skin [5]. The body takes on the forms of an apple and a pear due to fat deposition in particular physiological areas [6]. The more elevated region of the waist and abdomen is where fat develops in the case of an “Android apple”. Furthermore, there is some deposition on the shoulders, arms, and neck. Visceral fat, which is highly connected to the risk of type 2 diabetes, is the main reason of this body shape [7]. The thighs and buttocks of the resembling (gynoid) body are where fat is deposited. This body form has a low visceral fat content, which lowers the risk of weight-related illnesses [8].

Significant obesity clusters seen in particular geographic locations and contexts also reflect the significance of socioeconomic and environmental elements in "obesogenic" environments, since particular genetic and lifestyle factors influence an individual's risk of becoming obese as an adult.[9] Many research used principal component analysis or factor analysis to determine food patterns [10]. For several kinds of chronic ailments, including obesity, herbs have long been shown to be a useful and necessary source. In comparison to single-compound pharmaceuticals, herbs have less adverse effects, with the exception of a few allergic responses in vulnerable people. By lowering triglyceride levels, increasing metabolic rate, inhibiting pancreatic lipase, and suppressing appetite, medicinal herbs have showed beneficial effects on obesity. subsequently, they help people lose weight [11,12]. Winged prickly ash, or *Zanthoxylum armatum*, is a species of plant belonging to the Rutaceae family. It is a 3.5-meter-tall, aromatic, spiky, deciduous shrub that is native to China, Japan, Korea, and India. The wild plant *Zanthoxylum armatum* (Timbur) is utilized primarily as a condiment and medication, while it also has other therapeutic uses [13]. Numerous chemical substances were found in the different Zanthoxylum species sections that were the subject of previous phytochemical investigations. Phenylpropanoid-lignans, coumarins, alkaloids, aromatic and aliphatic amides, terpenes, and sterols are among the many secondary metabolites that have been found in this plant [14,15]. Furthermore, it has been established that a number of naturally present secondary metabolites found in many plants, including polyphenols, flavonoids, terpenoids, alkaloids, saponins, carboxylic acids, glycosides, and tannins, have anti-obesity properties through various modes of action [16,17]. Since *Zanthoxylum armatum* has the same collection of secondary metabolites, it can be assumed that it may exhibit a comparable anti-obesity action.

MATERIALS AND METHODS

Plant Materials

In the month of January, of *Zanthoxylum armatum* were collected from the local area of Sikkim.

Preparation of Extract

The seeds of *Zanthoxylum armatum* were collected and washed with tap water. They were then left to dry for seven days in a row under the shed. The dried sample was then macerated for 72 hours in a 70% hydroethanolic solution. The air-drying process was then used to dry the extract. After that, the extract was kept at 4°C after being wrapped in aluminum foil.

Phytochemical Screening [18]

To identify the presence of active ingredients, the crude extract went through qualitative analysis. Standard practices were used to conduct phytochemicals tests.

Standard Drug Solution Preparation

To prepare 0.35 mg/ml standard solution one Chitosan 350mg capsule is separated from capsule shell, powder is collected and dissolved in 1000 ml of distilled water.

Test Solution Preparation

High Dose(500mg): To prepare the test solution, 20 mg of hydroalcoholic extract of *Zanthoxylum armatum* dried seed is dissolved in 40 ml of distilled water and placed into the sample chamber.
Low Dose(250mg): To prepare the test solution, 20 mg of hydroalcoholic extract of dried *Zanthoxylum armatum*seed is dissolved in 80 ml of distilled water and placed into the sample chamber.

Method

Blood sample preparation:
Chicken blood was collected in a sterile vacutainers, and 2% EDTA was added in 60ml to prevent clotting. The tube was then spun in a centrifuge at 3000 rpm for 10 minutes. This separated the clear, yellowish serum from the red blood cells and clots. The serum was carefully transferred into a beaker using a micropipette or dropper, making sure not to disturb the sediment to avoid contamination. If needed immediately, the serum was used right away; otherwise, it was stored at -20°C or -80°C to preserve its quality. This serum is used for studies on its possible effects on fat formation and metabolism.

Procedure

The obtained blood serum was initially separated into four groups, each of which had three samples. Each group was then given the appropriate treatment and placed in an incubator set at 37°C for an hour in order to complete the required chemical reaction.

Group A (sample mixture A); 1ml blood serum with 0.1 ml distilled water.
Group B (sample mixture B); 0.1 ml of standard medication solution combined with 1 ml of blood serum.
Group C (sample mixture C): 0.1 ml test drug solution combined with 1 ml blood serum (250 ml/kg)
Group D (sample mixture D): 500 ml/kg of 1 ml blood serum and 0.1 ml test drug solution

Each sample mixture was then mixed with two to three drops of phenolphthalein and 10 milliliters of ethanol. The concentration of free fatty acid (FFA) in the serum was then determined by titrating the mixture against a (0.05N) NaOH solution and recording the average volume of NaOH necessary to neutralize the FFA.

The FFA concentration (mmol/L) was calculated using the formula- FFA (mmol/L) = $\frac{V \; X \; N \; X \; 1000}{Sample \;\; Volume \;\; (mL)}$

Where:
V: Volume of NaOH used (ml).
N: Normality of NaOH (0.05).
Sample Volume: 1ml (serum)

RESULT AND DISCUSSION

Extract Preparation
After maceration with a 70% hydroalcoholic solution for 72 hours, *Zanthoxylum armatum* seeds produced a yield of 5.85%.

Phytochemical Investigation
Through the different phytochemical investigation, the hydroalcoholic extract of *Zanthoxylum armatum* seeds showed the presence of different phytochemicals like- Alkaloid,Carbohydrate,Flavonoid,Tannin, Saponin,Polyphenol (Table 1)

Anti -Obesity Test
Fat storage in adipose tissue is promoted by free fatty acids (FFAs), which results in weight increase. Free fatty acid (FFA) levels that are high, make it harder to lose weight because they increase insulin resistance. FFAs induce the development of visceral adipose tissue, which is a primary contributor to obesity. Sustained high levels of FFA lead to inflammation, which makes obesity worse. FFAs cause a disturbance in hormone balance, which in turn causes an increase in hunger and food consumption, finally resulting in obesity [19]. By measuring the concentration of FFAs, the study aimed to assess the antiobesity effect of *Zanthoxylum armatum* seed against the non-treated control group and commercially available Chitosan 300mg. Both the 250 mg/kg and 500 mg/kg dosages of *Zanthoxylum armatum* seed demonstrate a strong anti-obesity impact when compared to the market standard of Chitosan capsule and control, and the standard Chitosan has once again demonstrated its effectiveness in comparison to control. By titrating the mixture against a (0.05N) NaOH solution and finding the average amount of NaOH required to neutralize the FFA, the concentration of free fatty acid (FFA) in the serum was ascertained. The FFAs analysis revealed that the control, standard, and test drugs, 250 mg/kg and 500 mg/kg, respectively, had FFAs concentrations of 143, 118, 135, and 131.1, according to "Table 2." Therefore, the extract from *Zanthoxylum armatum* seeds, the test sample, demonstrated strong anti-obesity properties when compared to both the conventional medication and the control (Figure1).

Zanthoxylum armatum dried seeds were found to have a considerable amount of alkaloids, flavonoids, polyphenols, saponins, and tannins, according to the results of the phytochemicals analysis. Phytochemicals such as flavonoids, alkaloids, polyphenols, and saponins can generally prevent the lipolysis process and promote the oxidation of free fatty acids, which lowers the blood and serum levels of FFAs [20]. In addition, because flavonoids have a high affinity for free fatty acids (FFAs), they can bind and sequester them, lowering FFA levels in blood serum by forming complexes with FFAs. Additionally, flavonoids can react with FFAs to create insoluble salts [21]. Because of their fundamental properties, alkaloids and polyphenols can react with free fatty acids (FFAs) to generate salts, which can reduce FFAs [22,23] It can be difficult to titrate FFAs because saponins can emulsify them. Emulsification is the process of creating a stable mixture of two or more liquids that don't normally mix [24]. Therefore, the *Zanthoxylum armatum* seed may be a powerful anti-obesity agent due to the presence of those phytochemicals.

CONCLUSION

The seeds of *Zanthoxylum armatum* has not been studied for their antiobesity properties, despite the plant's other parts has many traditional uses. Numerous biologically active components found in *Zanthoxylum armatum* are employed in the Indian medical system. Analyzing the phytochemicals in *Zanthoxylum armatum* seeds for potential anti-obesity effects was the aim of the current study. Alkaloids, polyphenols, carbohydrates, flavonoids, tannins, and saponins were found using phytochemical screening. At 250 mg/kg and 500 mg/kg, the hydroalcoholic extract of *Zanthoxylum armatum* seed demonstrated strong anti-obesity effects. Many traditional medical systems, including allopathic ones, have benefited greatly from the use of herbal medicinal plants. This review literature provides valuable information about the plant *Zanthoxylum armatum's* anti-obesity effects, which will serve as a focal point for further research.

ACKNOWLEDGEMENT

We wish to express our heartfelt thanks to Dr. ArnabSamanta, the head of the NetajiSubhas Chandra Bose Institute of Pharmacy. We are grateful for the assistance from our friends, family, and everyone involved in the lab.

ABSTRACT

Polycystic Ovary Syndrome (PCOS) is a protective hormonal disorder among women in their reproductive age that is identified as a cause of infertility, metabolic imbalance, and prolonged health issues as well as complications if proper diagnosis and treatment is not done in an early stage. Traditional and old diagnostic methods for clinical evaluation and ultrasound examination are frequently time-consuming and subjective, depending heavily on medical expertise. To deal with these endocrine challenges, this study proposes an AI and reliable ultrasound image-based classification framework for PCOS identification, utilising an enhanced Mobile Net architecture. The lightweight architecture of MobileNetV3-Small makes it particularly suitable for deployment in environments where resources are scarce, such as portable medical devices and mobile platforms. In this work, transformations of MobileNet models are introduced with regularisation techniques, resulting in improved feature extraction and robustness against noise in ultrasound imagery. All preprocessing, including contrast normalisation and noise reduction, is applied to ensure better visualisation of ovarian morphology and follicle distribution. The proposed model demonstrates much better classification performance in comparison to the standard deep learning architectures, achieving an accuracy of 98.2%, an AUC value of 99.1%, and a precision of 98.5%, while maintaining a compact model size and a faster inference speed.

The results indicate that the improved MobileNet-based approach provides a reliable, interpretable, and scalable solution for the early detection of PCOS with helpful clinical decision support and broader accessibility in low-resource healthcare settings.

Keywords : Transfer Learning, Medical Image Analysis, Polycystic Ovary Syndrome, Reproducibility, MLOps, Data Standardisation

INTRODUCTION

Polycystic Ovary Syndrome (PCOS) is a complex gynecological disorder that affects 8% to 13% of women in their reproductive age throughout the world, making it one of the most preventive causes of infertility and metabolic complications in women [1,2]. The syndrome is identified as a combination of the symptoms like hyperandrogenism, ovulatory dysfunction, and Polycystic Ovarian Morphology (PCOM) visible on ultrasound scans [3,4]. Premature and accurate diagnosis of PCOS is essential to minimize related risks such as type 2 diabetes, obesity, cardiovascular disease, and psychological distress [5,6]. Transvaginal or transabdominal ultrasound remains the standard imaging modality for assessing ovarian morphology [7]. The Rotterdam criteria (2003) established the presence of ≥12 follicles (2–9 mm in diameter) and/or ovarian volume >10 cm^3 as diagnostic indicators of PCOM [8]. With improvements in ultrasound resolution, current recommendations have increased the follicle count threshold to 20 per ovary while retaining the 10 cm^3 ovarian volume threshold [9]. However, ultrasound interpretation is subjective, highly operator-dependent, and problematic for inter-observer variability [10,11]. This subjectivity introduces the risk of misclassification during ovarian morphology overlaps between normal and pathological conditions [12]. Current in-depth learning methods have a trend as a transformative approach in medical imaging that can demonstrate higher accuracy and consistency over traditional manual interpretation [13]. CNNs have been largely implemented to determine diseases in ultrasound, MRI, and CT imaging [14,15]. Lightweight architectures are valuable due to their usefulness, reduced model size, and suitability for deployment in handheld ultrasound devices [16]. MobileNet variants have shown effective results in medical image classification tasks, such as breast cancer detection, lung disease screening, and fetal ultrasound analysis [17,18].

Limited studies have specifically described an automated PCOS classification from ovarian ultrasound images. Most existing works focus on follicle segmentation, ovarian detection, or applying heavy CNN architectures that are not optimized for real-time or portable clinical use [19,20]. To target these gaps, this study proposes an Improved MobileNet-based framework for ultrasound-based PCOS classification. The model integrates useful convolution operations with feature attention and preprocessing methods that are tailored for ovarian ultrasound, aiming to deliver high accuracy, robustness against noise, and reduced storage. This makes it highly suitable for clinical decision support and deployment in low-resource healthcare environments. In this work, an investigation is done on a systematic and multi-stage protocol for readiness with respect to data auditing, preprocessing, and verification of leakage. The task aims to implement a transfer learning model using MobileNetV3-Small, a lightweight model. The proposed approach is tested and evaluated in a held-out test set with a variety of metrics to show its clinical utility. The aim is to provide a comprehensive and reproducible outcome that enhances trust and serves as a methodology for future work in AI in healthcare.

Objectives

The main objective of this study is to develop a lightweight, reproducible deep learning framework for the accurate determination of PCOS using ultrasound imagery. Specifically, it aims to:

- Overcome the limitations of subjective and operator-dependent manual diagnosis by automating the process of image interpretation through AI.
- Optimize MobileNetV3-Small architecture for resource-constrained environments like mobile or portable ultrasound systems.

- Ensure data integrity, fairness, and reproducibility through extensive data readiness, augmentation, and validation protocols.

The proposed model seeks to offer a clinical decision support system that is efficient and can provide early detection, enhanced diagnostic reliability, and accessibility in low-resource healthcare setups.

Problem Formulation

The classification of PCOS from ovarian ultrasound images is defined as a binary supervised learning problem—differentiating between PCOS and Normal ovarian morphology. The dataset of 4,500 labelled images was preprocessed using contrast normalization, grayscale conversion, and augmentation to enhance feature diversity. Transfer learning with MobileNetV3-Small, pre-trained on Image Net, was applied, followed by two-phase optimization: (i) Classifier head training with frozen convolutional layers. (ii) Fine-tuning with selective unfreezing for domain adaptation. The model employed cross-entropy loss and Adam optimization to minimize the error while maintaining sufficient computational efficiency.

MATERIALS AND METHODS

The contents in this section describe the proposed methodology with different steps.

Dataset

This study used a private dataset with 4,500 2D transvaginal ultrasound images of ovaries collected from various gynaecology clinics. The dataset was pre-annotated by expert sonographers and clinicians. Based on these annotations, the task was formulated as a binary classification problem with two classes: PCOS: 2,150 ,images Normal: 2,350 images, To solve a real-world situation, the data was first given in predefined train (80%) and test (20%) folders.

Data Readiness and Standardisation Protocol

Before model training, the dataset underwent a rigorous data readiness protocol to verify its quality, integrity, and suitability for in-depth learning. This stage is compared with three critical sub-steps as described below.

Directory Audit and Integrity Check

This step describes the audit of the raw images. A Python script was run to iterate over the train and test directories. The manifest file maintains full file paths, file sizes (measured in bytes), and SHA-256 hashes for each file. Then, a pointer is performed as a hash that helps the program detect the exact duplicate file. The hash can create a duplicate hash file, which can alter performance. To examine the initial balance between the PCOS and Normal classes, their distributions were calculated and visualized as shown in Figure 1. This initial audit confirmed that all provided splits were good and there were no duplicate files.

Image Data Preprocessing

This step performs the following transformations before the model training using CNN.

- **Grayscale Conversion:** Original images contain RGB colour-based domain with ultrasound-specific information. Therefore, all images are converted into single-channel grayscale to perform a better result.
- **Resizing to Standardized Size:** CNNs require fixed-size image pixels. All collected ultrasound images were resized to 224 × 224 pixels to maintain compatibility with Image Net-pretrained models such as MobileNetV3-Small.
- **Padding and Channel Conversion:** Images were pad-resized to a square aspect ratio before resizing to avoid distortion of anatomical structures.

The improved MobileNetV3-Small accepts three-channel input. Therefore, the single grayscale channel was stacked into three channels. The visual result of this preprocessing is shown in Figure 2, where a montage of images was created before and after the transformations.

Data Normalization and Augmentation

To facilitate deeper learning and perform numerical stability during training, Z-score Standardization was applied to normalize the pixel intensity values of all ultrasound images. These statistics were calculated solely from the training set images and then applied to all sets (training, validation, and testing). By doing this, it prevents any information from the test set from leaking in. As seen in the pixel intensity histogram of the preprocessed images (Figure 3), the effect of normalization is demonstrated in Figure 5, which centers the data around a mean of 0. For the betterment of the generalisation capability of the proposed model to unknown data and to solve the risk of overfitting, data augmentation techniques were exclusively applied to the training set during the model training phase. The following augmentations were used: Random horizontal flips, Small rotations of up to 15°, Slight scaling variations

Data Splitting and Leakage Prevention

This step splits the dataset into train and test subsets for evaluating the model. However, a separate validation set is also required for hyperparameter tuning and early stopping. A validation set was created by allocating **20%** of the original training data. The split was performed in a stratified manner to preserve the data distribution between PCOS and Normal images, ensuring that both the reduced training set and the validation set maintained representative class proportions. To ensure no duplicate images existed, SHA-256 hashes of all images from the final training, validation, and testing splits were compared programmatically in a final leakage check.

Transfer Learning Methodology

Following the data standardization, the modeling stage commenced using a transfer learning approach to leverage knowledge from a model pre-trained on a large-scale dataset.

Model Architecture

The proposed work selectedthearchitectureMobileNetV3-Smallasthebasearchitecturedue to its lightweight design and efficiency. This model was pre-trained on ImageNet [21], achieves high performance under resource constraints, making it an excellent candidate for a potential deployment on clinical workstations or mobile devices. The transfer learning paradigm lever- ages the convolutional layers of this pre-trained model [22]. It aims to use trained convolutional layers that can get general-purpose features like edges, textures, and shapes, for these medical imaging tasks [23]. The proposed work loaded the pre-trained Model along with the ImageNet weights of the MobileNetV3-Small model. We froze the feature part of our model by setting requires_grad=False on all layers in the convolutional base. This stops their weights from changing at the beginning of training. To adapt MobileNetV3-Small for binary classification tasks, we replaced its original classifier head. The original classifier head was created for ImageNet (1000 classes). Thus, we trained the sequential custom head for this specific task. The new head has a layer called Global Average Pooling (GAP) layer followed by a Dropout layer with a dropout rate of 0.3 to reduce overfitting, and a final fully-connected Linear layer with two output neurons (for PCOS and Normal classes.

Baseline Head Training and Fine-Tuning

The training has two phases on a CPU-based system.

Baseline Head Training

In the initial training phase the parameters of the newly added classifier head were trained and updated on back bone network frozen time. The model was optimized using the Adam optimizer with a learning rate of 0.001 with 15 epochs. Cross-Entropy Loss was applied on it. To prevent over fitting, an premature stopping criterion with a patience of 3 epochs was applied by halting training. If the validation loss failed to improve for three consecutive epochs, the model checkpoint corresponding to the lowest validation loss was preserved for subsequent validation.

Fine-Tuning

After successful training of the classifier head, the model was taken through a fine tuning phase. In thi sphase, the last few layers of the convback bone were unfrozen enabling end-to-end training of the network. A small learning rate(10^{-5})was applied to allow gradual adjustments of the pre-trained feature extractors to minimize the risks of over-

fitting. This solution facilitated the adoption of high-level representations to the specific characteristics of the ultrasound imagery with improved task-specific performance.

Evaluation Metrics

The performance of the final and fine-tuned model was experiment on the held-out test set using a standard set of metrics for binary classification:

- Accuracy: The proportion of total predictions that were correct.
- Precision: The proportion of the positive predictions (PCOS) that were correct.
- Recall (Sensitivity): The proportion of actual positive cases(PCOS)that were correctly identified.
- F1-Score: The Harmonic Mean (HM)of precision and recall, providing a single measure that balances both the metrics.
- Area Under the Receiver Operating Characteristic Curve (AUC): A measure of the model'sabilitytodistinguishbetweenthetwoclassesacrossallpossiblethresholds, where a value of 1.0 indicates a perfect classifier.

RESULTS

This section presents the outcomes of the data readiness protocol and experimental performance of the trained in-depth learning model.

Outcomes of Data Standardization

The complete dataset, consisting of 4,500 images, was successfully processed in Stage 1 of the data readiness and flawless pipeline. The first audit uses no duplicates with existing or between the supplied train and test splits. The distribution of class isshowninFigure1.The PCOS class contains 2150 images (47.8%), and the Normal class contains 2350 images (52.2%). Overall, the dataset is well-balanced, and the fake resampling technique is not needed. All photos were processed similarly. All of them were adjusted to a 224 * 224 gray scale that requires the model, shown in Figure 2. The process of normalization adequately standardized the distribution of the pixel value. Verification of this step was carried out using two different plots, including Figure 3. The large intensity range seen in "Figure 3" was changed into a tight distribution centered at zero after normalization as seen in "Figure 5". After stratifying data for validation, the last splits were 2880 – training, 720 – validation, and 900 – testing images, with no data leakage between these sets.

Model Training Performance

The baseline head training phase performed with9epochsbeforetheearlystoppingcriterion was met. It indicates that the new classifier had converged continuously. The training and plot- ted log plotted shows a smooth and consistent decrease in training and validation loss which paired with a corresponding increase in accuracy (Figure 6). The validation loss closely tracked the training loss without significant decrease, which interprets that the model was generalizing better to unseen data and that the dropout and data

Result Analysis and Data Validation

The proposed model achieved 98.22% accuracy, 98.5% precision, and 99.1% AUC, outperforming existing CNN and baseline Mobile Net approaches. Data validation through SHA-256 hashing confirmed zero data leakage or duplication. Stratified sampling preserved class balance, ensuring fair evaluation. The model's robustness was verified by stable convergence curves and minimal over fitting, confirming its reliability for real-world deployment transformation issues. (Figure 4) were effective to protect from over fitting. Following this, the fine-tuning phase ran for an additional 5 epochs that led to a marginal but significant improvement in performance that the model got its feature extractors to the specific domain of ovarian ultrasound.

Experimental result son Test Set

The final and fine-tuned model was experimented on the held-out test set with 900 images. As summarized in Table1, the model described strong performance among all basic metrics. It achieved an overall accuracy of 98.2% that is reflecting a high proportion of correct classifications for both positive and negative cases.

Result Analysis and Data Validation

The proposed model achieved 98.22% accuracy, 98.5% precision, and 99.1% AUC, outperforming existing CNN and baseline Mobile Net approaches. Data validation through SHA-256 hashing confirmed zero data leakage or duplication. Stratified sampling preserved class balance, ensuring fair evaluation. The model's robustness was verified by stable convergence curves and minimal over fitting, confirming its reliability for real-world deployment.

DISCUSSIONS

The proposed Improved Mobile Net-based framework for PCOS classification from ultrasound images demonstrated superior diagnostic performance compared to conventional CNN models and baseline Mobile Net architectures. The improvements introduced include the optimized depth wise separable convolutions and feature attention mechanisms that can capture basic ovarian morphological differences such as follicle count, distribution, and stromal texture, which are critical in differentiating polycystic from normal ovaries. The lightweight nature of the proposed model is particularly significant in the context of resource-constrained healthcare settings. Traditional deep learning methods such as Res Net, Dense Net, or Efficient Net achieve high accuracy but are computationally intensive, making them less feasible for portable medical devices [4,24]. By maintaining a compact model size. And faster inference speed, the improved MobileNetV3-Smallensuresscalabilityforpoint-of-care applications, especially in rural or underserved regions where access to advanced diagnostic tools is limited. Another important advantage of the proposed approach is its flawless ultrasound noise removal and operator variability. Variations in probe orientation, ovarian visualization, and image quality often hinder consistency in manual diagnosis [5,25]. Through preprocessing methods added with attention-based feature learning, the model achieved stable classification performance across heterogeneous image samples.

CONCLUSIONS AND FUTURE WORK

Future directions of this study include (i) multi-centre validation for generalization, (ii) integration of explainable AI (Grad-CAM) to visualize the decision regions and build clinician trust, (iii) incorporation of automated follicle segmentation and phenol typing, and (iv) real-time deployment via mobile embedded diagnostic systems to enhance accessibility and patient outcomes This study designed a complete and descriptive framework for the detection of PCOS from end to end on ultrasound images. Although careful data readiness protocol and the usefulness of the MobileNetV3-Small transfer learning model with improved performance is achieved. The leading contribution of this work is its commitment to be transparent and reproducible, which is a promising step for clinical AI tools.To describe the limitations of the present study and for clinical translation. The endpoint of any algorithm should be successful under multi-center perceptions. In this situation, it needs to check whether the other centers can carry out their respective analysis without a problem. To determine it, if success can be predicted across different datasets at these centers, this model will apply XAI methods, such as GRAD-CAMs, to make a heat-map of the ultra sound image. This will indicate whether the model labels cases as normal or normal. It will make things more straightforward, and doctors will trust it more. It will assign phenotypes and automatically count and segment antral follicles that provides the clinician with improved quantitative data. Clinical Trial to perform, whether the proposed model is possible to be integrated into the clinical work flow. The trial will also experiment with the model's usefulness on diagnostic accuracy, efficiency, and patient outcomes.

ABSTRACT

Amlapitta is a common gastrointestinal disorder described in Ayurvedic literature, primarily caused by faulty dietary habits, irregular lifestyle, stress, and impaired digestive fire (*Agnimandya*). It closely resembles hyperacidity and acid-peptic disorders of modern medicine. Classical Ayurvedic texts emphasize *Shodhana* followed by *Shamana Chikitsa* for effective management, especially in Pitta-predominant conditions. This case report highlights the role of classical *Vamana Karma* followed by *Shamana Aushadhi* in the management of Amlapitta. A 36-year-old male patient presented with complaints of *Udar-uro Daha* (burning sensation in abdomen and chest), *Amlodgara* (sour belching), *Aruchi* (loss of appetite), *Hrillasa* and *Chardi* (nausea and vomiting), *Udarshula* (abdominal pain), *Klama* (fatigue), and *Bhrama* (vertigo) for six months. The patient had a history of tobacco chewing and had obtained only temporary relief from prior allopathic treatment. Based on clinical history, symptomatology, and Ayurvedic examination including *Ashtavidha Pariksha*, the patient was diagnosed with *Amlapitta*. Subjective assessment was carried out using graded symptom-based criteria. The patient underwent *Deepana–Pachana*, *Snehapana*, *Abhyanga*, and *BashpaSwedana* followed by classical *Vamana Karma*, which resulted in *Madhyama Shuddhi* with six *Vega*. This was followed by *Samsarjana Krama* for five days and *Shamana Chikitsa* with *Sutshekhar Rasa* and *AvipattikarChurna* for 15 days. Assessment after *Samsarjana Krama* and completion of *Shamana Chikitsa* showed marked improvement. Complete relief was observed in burning sensation, sour belching, nausea, vomiting, abdominal pain, and vertigo, while significant improvement was noted in appetite and fatigue. This case demonstrates that classical *Vamana Karma*

followed by appropriate *Shamana Chikitsa* is effective and safe in the management of Amlapitta by addressing both symptoms and underlying pathogenesis.

Keywords: symptomatology and Ayurvedic, gastrointestinal disorder

INTRODUCTION

The present era is characterized by stress and strain due to a highly competitive lifestyle. In an attempt to maintain social status, individuals increasingly adopt westernized dietary and lifestyle practices. As a result, human needs are expanding while available resources remain limited. In this struggle for survival, personal health is often neglected.[1] Changes in lifestyle, dietary habits, and behavioural patterns have led to a rise in functional and psychological disorders, among which gastrointestinal disorders are prominent.[2] Acharya Sushruta has stated that food consumed by a person with a disturbed mental state is not properly digested, even if it is wholesome and taken in appropriate quantity. Proper intake of food is essential for maintaining digestive power (*Agni*), which in turn sustains strength, health, and overall metabolism of the body. Despite advancements in science and technology, human beings continue to face numerous health problems, many of which are attributed to faulty dietary habits. It is estimated that nearly 80% of the top ten life-threatening diseases are related to improper diet and lifestyle.[3] Faulty lifestyle practices and inappropriate food habits disturb the process of digestion, leading to symptoms such as hyperacidity, dyspepsia, and indigestion, which account for approximately 50% of gastrointestinal disorders.[4]*Amlapitta* is one such disease of the gastrointestinal system. Classical Ayurvedic texts like *Charaka Samhita*, *Sushruta Samhita*, and *Ashtanga Hridaya* do not describe *Amlapitta* as a separate disease entity; however, its detailed description is found in texts such as *Madhava Nidana*, *Kashyapa Samhita*, and *Yogaratnakara*.

According to *Kashyapa Samhita*, *Amlapitta* is closely associated with dietary patterns, food habits, timing of meals, lifestyle, and nature of work. In *Amlapitta*, the quantity of *Pachaka Pitta* increases, and its normal bitter taste gets altered into an excessively sour nature.[5] Excessive intake of *Viruddha Ahara* (incompatible food), *Dushta Ahara* (spoiled food), *Ati-Amla* and *Vidahi Ahara* (sour and spicy food), *Pittakara Ahara*, *Guru* and *Abhishyandi Ahara*, excessive liquid intake, suppression of natural urges (*Vegadharana*), excessive alcohol consumption (*Atimadyapana*), and daytime sleep (*Divaswapna*) are described as etiological factors in Ayurvedic classics.[6] These factors lead to vitiation of all three *Doshas*, predominantly *Pitta Dosha*, resulting in impairment of *Agni* (*Agnimandya*). *Agnimandya* leads to improper digestion and metabolism, causing formation of *Ama*, which ultimately manifests as *Amlapitta*. Thus, *Agnimandya* and *Ama* formation are considered the root cause of the disease. In the management of *Amlapitta*, both *Shodhana* and *Shamana Chikitsa* play an important role. As *Pitta Dosha* is predominantly involved, *Vamana Karma* is advocated as a suitable *Shodhana* therapy in selected patients to expel vitiated *Doshas* and restore *Agni*. Following *Shodhana*, *Shamana Aushadhis* such as *Sutshekhar Rasa* and *AvipattikarChurna* are administered to pacify *Pitta Dosha*, improve digestive function, and alleviate symptoms like *Daha* (burning sensation), *Utklesha* (nausea), *Aruchi* (anorexia), *Chardi* (vomiting), and *Agnimandya*. The present case study highlights the effectiveness of *Vamana* followed by appropriate *Shamana* therapy in the management of *Amlapitta*.

Case Presentation

A 36-year-old male patient presented to the Outpatient Department (OPD) of our hospital, with chief complaints of *Udar-Uṛo Daha* (burning sensation in the abdomen and chest region), *Amlodgara* (sour belching), *Aruchi* (loss of appetite),occasional episodes of *Chardi* (vomiting), *Udarshoola* (abdominal pain), *Klama* (fatigue), and *Bhrama* (vertigo). The patient had been experiencing these symptoms for the past 6 months. The patient was a shopkeeper by occupation and reported a history of a tobacco chewing (2–3 times per day) for the last 5-6 years. He had previously taken allopathic treatment for a short duration, which provided only temporary symptomatic relief. There was no past history of hypertension, diabetes mellitus, or any other major systemic illness.

Examination
On physical examination, the patient's vital parameters were found to be within normal limits. Systemic examination did not reveal any abnormal findings. The findings of *Ashtavidha Pariksha* (eightfold examination) are summarized in

Subjective Criteria
Assessment of subjective parameters was carried out based on the gradation of clinical symptoms, as detailed in

Diagnosis
Based on the detailed patient history, presenting clinical features, and findings of physical and Ayurvedic examinations, the patient was diagnosed with *Amlapitta*.

Treatment
The patient was managed with classical *Vamana Karma* as *ShodhanaChikitsa*, considering the predominance of *Pitta Dosha* and presence of *Agnimandya*. *Vamana* was performed following proper *Purva Karma* to expel vitiated Doshas and normalize the digestive fire. After completion of *Vamana* and *Samsarjana Krama*, *Shamana Chikitsa* was administered for 15 days, which included *Sutshekhar Rasa* and *AvipattikarChurna*. These medicines were selected for their *Pitta-shamana*, *Agnideepana*, and *Amapachana* properties, helping to relieve symptoms such as *Daha*, *Amlodgara*, *Aruchi*, and *Utklesha*, and to prevent recurrence of the disease.

Observation and Results
Assessment of the patient was carried out at three stages—before treatment, after completion of *Samsarjana Krama*, and after 15 days of *Shamana Chikitsa*. Before treatment, the patient presented with moderate to severe symptoms of *Amlapitta*, including *Udar-uro Daha*, *Amlodgara*, *Aruchi*, *Klama*, *Udarshula*, *Hrillasa&Chardi*, and *Bhrama*. Following *Vamana Karma* and completion of *Samsarjana Krama*, a marked reduction in the severity of symptoms was observed, indicating effective elimination of vitiated *Doshas* and restoration of digestive function. Symptoms such as *Hrillasa&Chardi* and *Bhrama* showed complete relief at this stage, while significant improvement was noted in *Udar-uro Daha*, *Amlodgara*, and *Udarshula*. After completion of 15 days of *Shamana Chikitsa*, complete remission was observed in *Udar-uro Daha*, *Amlodgara*, *Hrillasa&Chardi*, *Udarshula*, and *Bhrama*. Symptoms of *Aruchi* and *Klama* showed substantial improvement with only minimal residual severity. Overall, the findings suggest that classical *Vamana Karma* followed by appropriate *Shamana Aushadhi* and dietary regulation is effective in the management of *Amlapitta*.

DISCUSSION

After achieving adequate *Deepana–Pachana* and completion of *Snehapana* with *Murchhita Go-Ghrita* in increasing doses until attainment of *Samyak Snigdha Lakshanas*, the patient was subjected to *Abhyanga* with *Murchhita Tila Taila* followed by *BashpaSwedana* using *Dashamoola Kashaya* for three consecutive days. On July 29, 2025, *Vamana Karma* was performed in the early morning hours according to classical Ayurvedic guidelines. *MadanphalaChurna* (3 g) mixed with honey (20 ml) was administered as the *Vamaka Yoga*, followed by intake of *Yashtimadhu Phanta* (approximately 2 liters) as *Vamanopaga Dravya*. The procedure resulted in *Madhyama Shuddhi*, with six *Vega* of vomiting, indicating satisfactory elimination of vitiated *Doshas*. The patient tolerated the procedure well without any complications. Following *Vamana*, appropriate *Paschat Karma* was advised, and *Samsarjana Krama* was followed for five days to restore digestive strength. After completion of *ShodhanaChikitsa* and *Samsarjana Krama*, the patient was administered *Shamana Aushadhi* in the form of *Sutshekhar Rasa* and *AvipattikarChurna* for 15 days. *Sutshekhar Rasa* is a classical formulation predominantly indicated in *Pitta*-dominant disorders and acts by pacifying aggravated *Pitta Dosha*, reducing *Amlata*, and alleviating symptoms such as *Daha*, *Amlodgara*, *Utklesha*, and *Chardi*. Its ingredients possess *Sheeta Virya*, *Pitta-shamana*, and *Agnisthapana* properties, thereby helping to normalize the function of *Pachaka Pitta* and restore digestive balance. *AvipattikarChurna* acts as a mild *Virechaka* and *Anulomana* drug, facilitating the expulsion of residual vitiated Pitta from the gastrointestinal tract while improving digestion and bowel regularity. Its

Deepana, *Pachana*, and *Mridu Rechana* actions help in preventing further formation of *Ama* and recurrence of symptoms. The combined administration of these *Shamana* drugs supports sustained *Pitta* pacification, strengthens *Agni*, and maintains the therapeutic benefits achieved through *Vamana Karma*.

CONCLUSION

Amlapitta is a lifestyle-related gastrointestinal disorder caused by faulty diet, stress, and impaired *Agni*. This case study shows that classical *Vamana Karma* followed by *Samsarjana Krama* and *Shamana Chikitsa* with *Sutshekhar Rasa* and *AvipattikarChurna* effectively relieved symptoms and restored digestive function. The treatment addressed the underlying *Samprapti* by eliminating vitiated *Pitta Dosha* and strengthening *Agni*, indicating that a combined *Shodhana* and *Shamana* approach is effective in the management of *Amlapitta*.

ABSTRACT

Neonatal hyperbilirubinemia is one of the most prevalent conditions that needs to be evaluated and treated in the first few days of life. Because hemolysis speeds up the synthesis of bilirubin and puts newborns at risk for severe jaundice and bilirubin-induced neurological dysfunction, it is a crucial factor among its many etiologies. In general, the causes of hemolysis can be separated into immune-mediated conditions like ABO and Rh incompatibility and non-immune conditions like pyruvate kinase deficiency, glucose-6-phosphate dehydrogenase deficiency, and red cell membrane defects like hereditary spherocytosis. Timely identification of these illnesses is aided by a methodical diagnostic strategy that begins with a clinical history and examination and progresses through focused laboratory testing and, when necessary, molecular analysis. In addition to facilitating genetic counselling and preventive measures in high-risk families, early diagnosis is crucial for directing management with phototherapy, exchange transfusion, and supportive care. The range of haemolytic causes of neonatal hyperbilirubinemia is highlighted in this review, along with useful evaluation approaches and the significance of early identification in lowering morbidity and long-term complications.

Keywords: Neonatal hyperbilirubinemia, Blood grouping incompatibility, G6PD deficiency, Treatment, Management.

INTRODUCTION

Neonatal jaundice (NNJ) denotes the yellow pigmentation of the skin, sclera, and mucous membranes resulting from elevated bilirubin levels in the blood and tissues (serum bilirubin >5 mg/dl) [1,2]. Bilirubin is produced from the breakdown of red blood cells (RBCs), specially through the breakdown of hemoglobin. The resulting unconjugated (indirect) bilirubin travels in the blood attached to albumin because it is not soluble in water. This bilirubin combines with glucuronic acid in the liver to generate conjugated bilirubin, which is a water-soluble form. After that, it is expelled through faeces and excreted into bile. However, the enzyme beta-glucuronidase in the intestine can convert some of this conjugated bilirubin back to unconjugated bilirubin, which is then reabsorbed into the bloodstream in a process known as enterohepatic circulation [3]. Neonatal jaundice is typically categorized as either pathologic or normal. The most prevalent kind of jaundice, which occurs in healthy infants, is physiological. Usually mild, it goes away on its own without any help. This kind of jaundice develops after the first 24 hours of life, peaks between 2 and 4 days (48 and 96 hours), and then progressively goes away by the second or third week. Babies' red blood cells (RBCs) have a shorter lifespan than adults', but they have higher haemoglobin levels at birth. Furthermore, neonates still have underdeveloped liver mechanisms that handle bilirubin that includes absorption, transport, and conjugation [4].Pathologic hyperbilirubinemia can have major consequences for babies, that’s why it must be identified early and treated appropriately.

Elevations of unconjugated bilirubin in the blood can be neurotoxic, meaning they can damage the brain [5]. A disorder known as kernicterus can result from bilirubin accumulation in the brainstem, hippocampus, cerebellum, globus pallidus, and subthalamic nuclei because it can pass the blood–brain barrier. Both acute and chronic neurological issues can result from bilirubin's effects on the brain, which are referred to as bilirubin-induced neurologic dysfunction (BIND). The bilirubin level's level and duration of elevation are the primary determinants of risk [6]. Haemolysis, in which red blood cells degrade more quickly than usual, is the most frequent cause of pathologic unconjugated hyperbilirubinemia. Anaemia becomes the primary clinical issue in persistent haemolysis as the baby grows and conjugation and excretion improve, although the liver's ability to remove bilirubin is still immature in the first few days after delivery [7]. Therefore, hemolysis continues to be a major contributor to hyperbilirubinemia, especially in newborns and individuals with underlying hematological conditions. It is essential to identify these reasons early in order to avoid consequences like kernicterus and persistent anemia. Blood tests, which offer crucial details regarding the location, mode, and degree of red cell death, are primarily used to assess hemolytic causes. The pathophysiology of hemolytic hyperbilirubinemia is the main topic of this review paper, which also emphasizes the significance of different hematological and biochemical tests in determining the underlying causes of the condition.

Causes and risk factors of hyperbilirubinemia

Neonatal hyperbilirubinemia arises from a variety of causes that can be broadly classified into physiological and pathological categories. Physiological jaundice is the most common and is related to immature hepatic conjugation mechanisms, increased red cell mass, and shorter neonatal red cell lifespan. In contrast, pathological hyperbilirubinemia is associated with underlying hemolytic, metabolic, infectious, or structural abnormalities.

Immune causes of hemolysis primarily result from blood group incompatibilities, most commonly involving the ABO and Rh systems, although mismatches in other red cell antigens can also contribute. These incompatibilities lead to maternal alloantibody formation and subsequent immune-mediated destruction of fetal or neonatal red cells.

In contrast, non-immune causes of hemolysis are related to intrinsic or extrinsic factors affecting the red blood cells. These include inherited conditions such as red cell enzyme deficiencies (e.g., glucose-6-phosphate dehydrogenase deficiency), structural defects in the red cell membrane (e.g., hereditary spherocytosis, elliptocytosis), and hemoglobin disorders (e.g., thalassemias, sickle cell disease). Additionally, extrinsic factors like neonatal sepsis can also precipitate hemolysis by increasing red cell destruction and impairing hepatic bilirubin metabolism, thereby aggravating hyperbilirubinemia.

Immune causes of hyperbilirubinemiahemolysis

ABO blood group incompatibility

A, B, AB, and O are the four primary blood group types according to the ABO system. When exposed to comparable antigens in food or microorganisms, people with type O blood can generate anti-A and anti-B antibodies [8]. Only 1%–4% of infants have detectable ABO haemolytic illness, despite 15%–25% of pregnancies including ABO incompatibility between the mother and fetus [9]. Black people often have larger amounts of these antibodies than Caucasians, the disorder is more prevalent among Black populations [10]. Due to a blood type mismatch between the mother and the infant, ABO incompatibility is currently thought to be the main cause of newborn jaundice [11].

Rh incompatibility

There are over 50 antigens in the Rh blood type system, the most significant ones are D, C, c, E, and e [12]. If a person's red blood cells have the D antigen, they are said to be Rh-positive; if not, they are said to be Rh-negative. The most well-known cause of haemolytic disease of the foetus and newborn (HDFN) is Rh incompatibility. When a Rh-positive foetus is carried by a Rh-negative mother, this syndrome develops. IgM antibodies, which are unable to pass through the placenta, are typically produced in response to the initial exposure to foetal red blood cells. The volume of foetal blood entering the mother's circulation, the intensity of the immunological response, and the presence or absence of ABO incompatibility are some of the variables that determine whether the mother gets sensitized. Later pregnancies with Rh-positive foetuses result in HDFN because the mother's IgG anti-D antibodies cross the placenta and kill the foetal red blood cells. Unlike ABO incompatibility, the condition usually gets worse with each consecutive Rh-positive pregnancy. Sensitisation is more likely to occur in situations such foetal maternal haemorrhage. However, by eliminating foetal red blood cells before maternal sensitisation takes place, coexisting ABO incompatibility can actually reduce it [13,14].

Hemolytic Disease of the Foetus and Newborn (HDFN)

Hemolytic disease of foetus and newborn. (HDFN) a dangerous and occasionally fatal disorder known as haemolytic disease of the foetus and newborn (HDFN) can result from maternal–fetal blood group incompatibility (such as ABO, Rh, or other minor antigens) [15]. This occurs when the mother's immune system develops antibodies against foetal red cell antigens, a condition known as alloimmunisation. These maternal antibodies have the ability to pass through the placenta, get into the bloodstream of the foetus, and result in haemolysis and associated problems. Fetomaternal haemorrhage during pregnancy, delivery, obstetric difficulties, or invasive treatments can all result in alloimmunisation [16]. Importantly, alloimmunisation can be triggered by as little as 0.1 mL of foetal blood entering the mother's circulation [17].

Non-Immune causes of hyperbilirubinemiahemolysis

Glucose-6-Phosphate Dehydrogenase (G6PD) Deficiency

glucose-6-phosphate dehydrogenase (G6PD) deficiency is one of the most prevalent hereditary enzymatic diseases, affects around 500 million people globally, or roughly 5% of the world's population. Regular neonatal screening programs include G6PD deficiency in a number of high-prevalence areas.

In the pentose phosphate pathway, the G6PD enzyme is essential for converting NADP to NADPH. The antioxidant defence of red blood cells depends on NADPH. Red blood cells that don't have enough NADPH are more susceptible to oxidative stress, which can cause haemolysis.

Due to X-chromosome inactivation, heterozygous females exhibit varying manifestation of the condition, whereas males are more likely to be affected since it is inherited in an X-linked recessive pattern [18-20].

By 2020, there were about 230 different forms of the X chromosome-based G6PD gene [21].

G6PD variations are divided into four major groups by the World Health Organisation (WHO) [22]:

- Class A: Severe deficiency (less than 20% enzyme activity), which frequently results in chronic haemolytic anaemia of non- spherocytic.

- Class B: Moderate to severe deficiency (<45% activity), usually seen as acute haemolytic anaemia or newborn jaundice brought on by fava bean consumption, medications, or infections
- Class C: little haemolysis and mild to nonexistent deficiency (>60% activity).
- Class U: Variants whose clinical significance is unknown because of insufficient data.

However, because clinical severity is highly dependent on the underlying genetic variation, enzyme activity alone is not always a good indicator of symptoms. [23].

Hereditary spherocytosis

hereditary spherocytosis (HS) is caused by the defects in red blood cell (RBC) membrane proteins. An inherited haemolytic condition that shortens the lifespan of the cells and causes structural instability [24]. Proteins 4.2, band 3, α-spectrin, β-spectrin, and ankyrin-1 are the most frequently impacted [25]. Hereditary spherocytosis (HS) is the predominant hereditary haemolytic anaemia among individuals of Northern European ancestry, occurring in around 1 in 1,000 to 1 in 5,000 live births. Approximately 75% of cases exhibit an autosomal dominant inheritance pattern, whilst the remainder results from recessive inheritance or de novo mutations. Mutations in the ankyrin, β-spectrin, and band 3 genes are predominantly linked to dominant phenotypes [26]. From individuals who have no symptoms to those who have severe, transfusion-dependent anaemia, the clinical severity of HS varies greatly. During the prenatal period, affected foetuses may show signs of severe anaemia or hydrops fetalis. While anaemia, splenomegaly, and jaundice—the classic triad found in older children and adults—are rare in neonates, jaundice, or hyperbilirubinemia, is usually the main sign in newborns. Interestingly, during the first week of life, almost 50% of newborns with HS do not exhibit anaemia [27,28].

Sepsis

Due to a combination of accelerated RBC destruction and compromised liver function, neonates with sepsis are particularly vulnerable to severe jaundice. The prevalence varies by region; in Europe and North America, severe jaundice or kernicterus is reported in approximately 2% of newborns, but in Africa and Asia, it is 14% and 31%, respectively. In low- and middle-income nations, where infection-related hyperbilirubinemia continues to be a major cause of morbidity and mortality, the risk is particularly high. In this context, sepsis-induced oxidative damage to red blood cells is the primary cause of unconjugated hyperbilirubinemia.

Numerous mechanisms lead to haemolysis, such as:

- bacterial lipopolysaccharide insertion into red blood cell membranes, changing their characteristics
- haemolytic pathogens and pore-forming toxins;
- complement activation
- RBC metabolic dysfunction
- RBC apoptosis
- disseminated intravascular coagulation (DIC).

In newborns with hyperbilirubinemia, sepsis is also regarded as a significant neurotoxicity risk factor because it raises the possibility that bilirubin will breach the blood–brain barrier and result in conditions like kernicterus [29-31].

Bilirubin metabolism and pathophysiology

Heme is catabolised by the RES (reticuloendothelial system) to produce bilirubin. Haemoglobin (Hb) is the main source (80–85%), but other heme-containing substances such cytochrome, myoglobin, catalase, and peroxidase also contribute. In haemolytic anaemia, erythropoiesis increases several times, and senescing red blood cells (RBCs) provide an even higher proportion of heme. The liver is thought to be responsible for 13–23% of the body's total heme synthesis. The percentage of non-Hb heme may increase in conditions such as porphyria, protoporphyria, and lead poisoning.Since the mother can no longer eliminate bilirubin from the placenta after delivery, the infant must be able to metabolise and eliminate it on their own. Consequently, the newborn is physiological. Jaundice can develop as a result of bilirubin production, excretion, and enterohepatic circulation. Reports state that neonates produce about twice as much bilirubin as adults, at 8.5 mg/kg/day. This is because neonates have a shorter erythrocyte lifetime (52

days) opposite to adults (120 days)[32].Neonatal hyperbilirubinemia is the outcome of high production due to an increased rate of RBC breakdown and the baby's limited ability to eliminate it. Compared to adults, newborns—especially those born prematurely—produce more bilirubin. It is challenging to obtain unconjugated bilirubin from newborns because they have a limited capacity for bilirubin conjugation. [33].Once RES forms a reversible covalent bond with albumin, bilirubin is released into plasma. Albumin has a strong affinity for its first site and a low affinity for its second site. When albumin levels are low, UCB (unconjugated bilirubin) may bind with high molecular weight lipoprotein in addition to competing for binding with other molecules such as FFA(Free fatty acids) and sulfonamides. Under normal conditions, plasma contains either very little or no unbound (free) UCB. When bilirubin binds with albumin, it prevents tissue precipitation, decreases glomerular filtration, and limits its escape from the circulatory space (34).

Clinical manifestation of hyperbilirubinemia

A thorough history is taken before evaluating a newborn who exhibits jaundice. Important factors include the timing of the beginning of jaundice, the sufficiency of feeding, maternal serology results, delivery details, family history of jaundice or blood disorders, and pregnancy difficulties. Important hints on the type of jaundice may also be found in the colour of the stool and urine.minor risk factors are male gender, macrosomic newborns of diabetic mothers, polycythaemia, high-intermediate blood bilirubin, and maternal age greater than 25 years.

According, to the American Academy of Paediatrics (AAP) every 12 hours from the time of birth until hospital release, all babies should be visually screened for jaundice. Additionally,physicians should also determine the risk factors for severe hyperbilirubinemia.

For neonates born after 35 weeks of gestation, the major risk factors include:

- Jaundice appearing in the first 24 hours of life
- Predischarge bilirubin in high-risk zone (Bhutani nomogram)
- Blood group incompatibility with a positive direct agglutination test
- Gestational age 34–36 weeks
- Previous sibling with jaundice requiring phototherapy
- Exclusive breastfeeding, particularly if associated with poor intake or excessive weight loss
- Hemolytic disease (e.g., G6PD deficiency, hereditary spherocytosis)
- Presence of significant bruising or cephalohematoma
- East Asian ethnicity

Newborns should ideally be examined in the daytime to check for jaundice. Clinical evaluation by itself, is frequently unreliable, especially in newborn with darker skin tones or those who have already undergone phototherapy [36–38].

Acute Bilirubin Encephalopathy

Depending on when symptoms first appear, newborns with severe unconjugated hyperbilirubinemia may have different clinical signs of bilirubin encephalopathy. It is unclear exactly what bilirubin level causes neurotoxicity, and kernicterus has been seen in newborns whose postmortem results show no significantly elevated bilirubin levels.

Usually, acute bilirubin encephalopathy develops in three stages:

• Phase 1 (first 1-2 days): Hypotonia, lethargy, seizures, irritability, or poor feeding.

• Phase 2 (midway through the first week): deteriorating neurological symptoms, including retrocollis, opisthotonus, and elevated extensor muscle tone.

• Phase 3 (after the first week): Severe symptoms such apnea, repeated seizures, muscle rigidity, and stupor or coma.

Chronic Bilirubin Encephalopathy (Kernicterus)

Severe acute bilirubin toxicity or untreated bilirubin poisoning can result in chronic bilirubin encephalopathy, a permanent and incapacitating neurological disorder. The age at which it manifests affects its manifestations.

• During the first year of life, infants may have delayed motor milestones, hypotonia, exaggerated deep tendon reflexes, and the required tonic neck reflex.

• After the first year: Sensorineural hearing loss, upward gaze abnormalities, dental enamel hypoplasia, and movement difficulties (most frequently choreoathetoid cerebral palsy) are among the clinical characteristics.

Therefore, a transcutaneous bilirubin (TcB) test or a total serum bilirubin (TSB) measurement should be used to confirm any clinically severe jaundice. The underlying cause of pathologic jaundice may be found with the aid of a targeted physical examination. Pallor, petechiae, cephalohematoma, severe bruises, hepatosplenomegaly, weight loss, and dehydration are important symptoms. Clinical signs of bilirubin encephalopathy, including poor feeding, lethargy, irregular sleep patterns, aberrant muscular tone, and seizures, should also be evaluated in all newborns with jaundice. Remarkably, up to 15% of newborns with kernicterus may show no symptoms at all during the neonatal period [39,40].

Laboratory evaluation and diagnostic Approach

According to the American Academy of Paediatrics (AAP) every infant should have their bilirubin levels evaluated 24 to 48 hours after birth. Bilirubin should be checked before the baby leaves the hospital if they are released earlier. A transcutaneous bilirubin (TcB) device is typically used for the initial examination, and a total serum bilirubin (TSB) test is used for confirmation if necessary. One effective screening method for hyperbilirubinemia is the transcutaneous bilirubin (TcB). It lessens the need for neonates to have blood drawn frequently. Its precision is constrained, though, in babies with darker skin tones and those who have had phototherapy, where the outcomes might be less trustworthy. [42, 43].

Assessing neonatal jaundice begins with a comprehensive physical examination of the newborn and a full family and pregnancy history. Additional research is required to determine the underlying aetiology of jaundice that seems pathological.

Key diagnostic tests include:

- Maternal and neonatal ABO and Rh typing – to detect blood group incompatibility.
- Direct Antibody Test (DAT/Coombs Test) – to confirm immune-mediated hemolysis.
- Complete Blood Count (CBC) – to assess anemia and overall hematological status.
- Reticulocyte Count – elevated values suggest increased red cell turnover due to hemolysis.
- Peripheral Blood Smear – to identify abnormal red cell morphology.
- Glucose-6-phosphate dehydrogenase Testing(G6PD) – to detect enzyme deficiency, a common cause of hemolytic jaundice.
- Pyruvate kinase (PK) deficiency testing - to identify a genetic haemolytic cause of neonatal hyperbilirubinemia[44,45].

Treatment/ management

The two cornerstones of treatment for infants with unconjugated hyperbilirubinemia are exchange transfusion and phototherapy. Depending on how effectively the infant responds to these treatments, more therapy modalities might be used. The presence of neurotoxicity risk factors, the neonate's gestational age, and the hourly total serum bilirubin (TSB) level all influence the treatment decision.

Phototherapy

The first-line treatment for pathologic unconjugated hyperbilirubinemia is phototherapy (PT). It successfully reduces the risk of bilirubin neurotoxicity and the requirement for exchange transfusion by bringing total serum bilirubin (TSB) down to safe levels. The presence of neurotoxicity risk factors, the infant's gestational age, and the hour-specific TSB concentration all influence the threshold for starting physical therapy.

Risk factors for neurotoxicity that call for starting PT at lower TSB levels include:

• Serum albumin <3.0 g/dL.

• Neonatal gestational age <38 weeks

• Deficiency inglucose-6-phosphate dehydrogenase (G6PD), positive direct antiglobulin test (DAT), other haemolytic disorders

•Severe clinical decline throughout the previous 24 hours;
•sepsis
Severe clinical decline throughout the previous 24 hours; sepsis Standardised recommendations for PT initiation in preterm infants are still scarce. As a result, numerous hospitals create their own exchange transfusion and phototherapy procedures, usually based on gestational age and birth weight [46–48]. The first effective treatment for jaundice was Exchange transfusion (ET), which was introduced in 1947.[49] Since phototherapy was created in the 1950s, ET has become the second-line treatment for severe unconjugated hyperbilirubinemia. [50,51]. Neonatal failure to react to PT or a TSB level at the exchange transfusion threshold are among the indications for this treatment. The TSB level and rate of rise, neonatal age (i.e., hours or days after birth), and risk factors for neurologic problems are some of the parameters that are used to determine the threshold to start exchange transfusion. Hemolysis-causing antibodies and bilirubin are quickly eliminated from the baby's bloodstream by ET. Aliquots of the neonate's blood are swapped out for crossed-matched donor blood during a double-volume exchange blood transfusion (160–180 ml/kg). Since the majority of total body bilirubin is extravascular, the TSB level right after ET is around 60% of the pre-exchange level; however, equilibrium causes that level to rise to 70% to 80% of the pretreatment level.The neonate's vital signs should be regularly checked during ET. Potential complications include electrolyte abnormalities (e.g., hypocalcaemia and hyperkalaemia), cardiac arrhythmias, thrombocytopenia, blood-borne infections, portal vein thrombosis, graft versus host disease, necrotising enterocolitis (NEC), and TSB, CBC, serum calcium, glucose, and electrolytes. These should all be rechecked after the procedure [52,53]. After an exchange transfusion, phototherapy should continue until the bilirubin level is low enough to safely stop PT(Phototherapy).

Intravenous Immunoglobulin (IVIG)
Intravenous immunoglobulin (IVIG) is recommended. when immune-mediated haemolysis results in unconjugated hyperbilirubinemia. It works by preventing red blood cells' (RBCs') Fc receptors from functioning, which lessens antibody-mediated haemolysis. When, in spite of intense phototherapy, the TSB stays within 2–3 mg/dL of the exchange transfusion threshold, the American Academy of Paediatrics (AAP) advises IVIG delivery [54,55]. Despite IVIG's widespread usage in clinical practice, there is conflicting information about how effective it is at lowering the need for exchange transfusions. However, it remains a valuable supplementary treatment for severe unconjugated hyperbilirubinemia, especially when immune-mediated processes are at play.

Recent advances and future perspectives
The diagnosis and treatment of neonatal hyperbilirubinemia have advanced significantly in recent years, with improvements aimed at enhancing long-term results, safety, and accessibility. The advent of home phototherapy programs, which enable newborns to get treatment in a familiar setting without requiring prolonged hospitalisation, is one of the most promising advancements. Home-based phototherapy has been shown to be safe and effective, reduce the strain on healthcare systems, and improve parental adherence and satisfaction (56) Significant advancements in phototherapy equipment and diagnostic techniques have also been observed. Modern phototherapy equipment can produce optimal light intensity throughout various wavelengths and is more portable and energy-efficient. These characteristics reduce the possibility of side effects while increasing therapeutic efficacy. Simultaneously, improvements in diagnostic instruments, especially non-invasive methods like transcutaneous bilirubinometry, have improved accuracy and dependability and made it easier to identify hyperbilirubinemia early. When taken as a whole, these developments provide more effective and customised newborn care (57).

To further enhance results, researchers are looking into pharmaceutical adjuncts in addition to phototherapy. Tin-mesoporphyrin, a heme oxygenase competitive inhibitor, has shown promise as a bilirubin synthesis inhibitor. Its therapeutic applicability is still being evaluated, despite the fact that preliminary research supports its effectiveness. Long-term safety concerns and the requirement for bigger multicenter trials underscore this. The application of wearable technology for bilirubin monitoring is a new and quickly developing field. The viability of wearable, non-invasive devices that can continually assess neonatal bilirubin levels has been shown by recent pilot studies. By facilitating real-time monitoring, early detection of sharply increasing bilirubin levels, and prompt action, such technology has the potential to revolutionise clinical practice and reduce the likelihood of serious consequences like

kernicterus (58). Going forward, a more thorough and patient-centered strategy to neonatal hyperbilirubinemia is probably going to be shaped by the combination of wearable monitoring devices, pharmaceutical adjuncts, optimised phototherapy equipment, and home-based treatment. The use of genetic profiling to detect infants at high risk, the application of artificial intelligence to forecast bilirubin trajectories, and the expansion of affordable technologies to environments with low resources are possible future avenues. When taken as a whole, these developments mark a paradigm change in neonatal care towards safer, more individualised, more technologically sophisticated care.

DISCUSSION

One of the most prevalent conditions during the neonatal era is neonatal hyperbilirubinemia. The majority of cases are physiologic jaundice, but in order to avoid consequences like acute bilirubin encephalopathy and kernicterus, it is imperative to promptly identify the pathologiccauses. Hemolysis, elevated bilirubin load, or physiologic immaturity are the most common causes of unconjugated hyperbilirubinemia. While enzyme abnormalities like pyruvate kinase deficiency and glucose-6-phosphate dehydrogenase (G6PD) emphasise the genetic basis of excess hemolysis, immune-mediated factors like ABO and Rh incompatibility continue to be significant worldwide. Cephalohematoma and jaundice from breastfeeding can play a role, though they often have a benign course if detected early. Despite being less frequent, conjugated hyperbilirubinemia is always harmful. Since results rely on prompt surgical repair, biliary atresia is the most urgent cause. Cholestatic syndromes, metabolic liver disorders, and newborn hepatitis are further problems. Therefore, it is crucial to measure direct bilirubin when assessing chronic or unusual jaundice.

Despite progress, problems still exist. Preventable morbidity is exacerbated in settings with low resources due to obstacles to universal predischarge screening and TcB provision. Additionally, there is limited access to genetic testing for metabolic and haemolytic disorders. These gaps could be filled by creating region-specific screening methods and affordable point-of-care diagnostics

CONCLUSION

The causes of neonatal hyperbilirubinemia are many and include hemolytic, metabolic, cholestatic, and physiological immaturity. To differentiate benign from pathological cases, a systematic evaluation is necessary, starting with risk assessment and bilirubin measurement and continuing with specific laboratory testing. Hemolytic disorders and conjugated hyperbilirubinemia require special attention since they both pose serious hazards if they are not identified right away. Although universal screening and advanced diagnostic technologies have enhanced early detection in high-resource environments, significant obstacles still exist in low- and middle-income nations. Reducing avoidable morbidity and death requires enhancing standard screening procedures, guaranteeing access to reasonably priced point-of-care diagnostics, and raising awareness among medical professionals. Finally, ensuring long-term neurodevelopmental outcomes requires prompt and methodical assessment of newborn hyperbilirubinemia.

ABSTRACT

The current antibiotic medications are less effective and more prone to resistance due to the growing global problem of AMR. Because of their wider range of action, quick bactericidal kinetics, and decreased tendency to acquire resistance, alternative drug discovery programs based on the utilization of AMPs and peptidomimetics have gained popularity. An overview of contemporary synthetic approaches, including sophisticated methods and bio-orthogonal chemistry, as well as the traditional solid-phase peptide synthesis (SPPS), can be utilized to design and optimize these peptides. The latter enables targeted alteration of AMPs under physiological settings by chemoselective conjugations, native chemical ligation, and azide–alkyne cycloadditions that are both strain- and copper-promoted. Apart from these techniques, different pharmacological activities of AMPs and peptidomimetics have been discovered, such as intracellular targeting of bacteria, immune modulation, and breakdown of cell membranes. Structurally varied frameworks are provided via bio inspired techniques, particularly TCM-inspired molecules. Even if progress has been achieved, issues such as metabolic instability, synthesis challenges, and expenses still exist. To overcome these obstacles, rational design concepts, computer simulation methods, hybrid systems, and biorthogonal approaches will be integrated.

Keywords: Antimicrobial Resistance, Antimicrobial Peptides (AMPs), Peptidomimetics, Solid-Phase Peptide Synthesis (SPPS), Biorthogonal Chemistry, Structure-Activity Relationship (SAR), Traditional Chinese Medicine (TCM).

INTRODUCTION

Global Burden of Infectious Diseases

As one of the main causes of morbidity and mortality in many regions of the world, particularly in developing and impoverished nations, infectious diseases continue to be a major global health concern[1]. According to the World Health Organization, infectious diseases include infections caused by bacteria (such as sepsis and tuberculosis), viruses (such as influenza and HIV), and fungi (such as candidiasis and aspergillosis). ICD-11 provides a systematic framework for categorizing infectious diseases. Urbanization, climate change, and international travel have increased the prevalence of emerging and reemerging illnesses. Furthermore, people who have compromised immune systems as a result of diseases like chemotherapy and transplant surgery are more susceptible to infections. Because pathogens tend to adapt easily, it is challenging to regulate the progression of disease, even with current technology[2][3].

Antimicrobial Resistance (AMR): Need for Novel Therapeutics

The effectiveness of current medical therapies is threatened by antimicrobial resistance (AMR), a major public health concern[4]. The widespread overuse and misuse of antibiotics in clinical treatment, agriculture, and animal husbandry is the main cause of AMR's rapid rise. Conventional antibiotics that prevent the synthesis of proteins, the creation of cell walls, or the reproduction of genetic material are becoming less and less effective. Additionally, the high cost of research, strict regulations, and low financial gains limit the search for novel antibiotics. Finding alternative antimicrobials with unique mechanisms of action that can overcome resistance is therefore imperative[5][6].

Peptides and Peptidomimetics as Next-Generation Antimicrobials

Peptidomimetics and antimicrobial peptides are great alternatives to the antibiotics that are already in use. Due to their capacity to damage cell membranes, antimicrobial peptides are a crucial part of innate immunity and exhibit broad antimicrobial action against a variety of pathogens, including bacteria, fungi, viruses, and parasites[7]. Peptidomimetics, on the other hand, are artificial substances created using artificial amino acids and further modifications to boost their stability and stop hydrolysis. Both types of peptides offer a method for SAR research and have great target selectivity and low cytotoxicity [8][9].

Relevance to Traditional Chinese Medicine (TCM)

An abundance of bioactive compounds with immune-modulating and antibacterial properties can be found in TCM[10]. Traditional Chinese medicine's ingredients serve as models for developing new medications. In order to create better versions, current scientific advances entail separating the active ingredients and copying their structure. The lack of uniform composition, dosage, and quality is still a challenge. When paired with contemporary techniques like solid-phase peptide synthesis and bioorthogonal chemistry, traditional Chinese medicine provides a wealth of knowledge[11][12]

Novelty and Scope of the Present Review

There are still a few comprehensive reviews that address every facet of the translational pipeline, despite the numerous reviews that have been published on antimicrobial peptides (AMPs), peptidomimetics, peptide synthesis, or antimicrobial mechanisms independently. By combining intelligently designed peptides, SAR research, advanced synthesis methods (solid-phase peptide synthesis, microwave-assisted synthesis, green chemistry, click chemistry, and bioorthogonal chemistry), pharmacology studies, quality control, and clinical translation into a single image, the current review offers a comprehensive overview. Additionally, novel developments, including nanoparticle-based delivery methods, TCM-inspired peptide scaffolds, aided AI peptide discovery, and bioorthogonal chemistry applications in next-generation antimicrobial medicine, are significantly addressed. In order to combat antibiotic resistance, this comprehensive review attempts to offer a translational guideline for logically developing and refining peptide-based antimicrobial medications[13][14].

Classification and Design of Peptide-Based Antimicrobials

Natural Antimicrobial Peptides (AMPs)

Endogenous molecules of the innate immune system, antimicrobial peptides (AMPs) are found in bacteria, plants, insects, and humans. AMPs, which are typically made up of 10 to 50 amino acid residues, are cationic and amphipathic, allowing them to attach themselves specifically to the negatively charged surfaces of microbes. AMPs can be loop, extended, α-helical, or β-sheet peptides, depending on the secondary structure. AMPs most frequently work by disrupting membranes using barrel-stave, toroidal pore, or carpet models; however, some of them also operate as inhibitors of intracellular activities such as the creation of DNA, RNA, and proteins[15][16][17].

Synthetic Peptides

The synthetic peptides were developed to get around issues with toxicity and stability, among other issues. Solid phase peptide synthesis makes it possible to rationally modify peptides utilizing a variety of techniques, including as amino acid substitution, end-group manipulation, peptide cyclization, and sequence length reduction, all of which increase the peptides' efficacy, selectivity, and resistance to degradation. This method offers useful data regarding the SAR of possible leads[18][19].

Peptidomimetics (β-Peptides, Peptoids, Stapled Peptides)

Chemically modified peptide mimics known as peptidomimetics have biological activity that is comparable to that of natural peptides and have better pharmacokinetics and high stability. β-peptides, peptoids, and stapled peptides are examples of peptidomimetics because they have stable secondary structures and are extremely resistant to protease degradation. Future antimicrobial medications may employ peptidomimetics[20][21].

Structure–Activity Relationships (SAR) of Peptide-Based Antimicrobials

Since chemical properties and biological activity are correlated, SAR analysis is essential for the logical design of peptide antimicrobials. A balanced ratio of net positive charge, hydrophobicity, amphiphilicity, peptide length, secondary structure, and amino acid makeup provides the antimicrobial peptides' effectiveness. While a high charge can be more harmful, a positive charge between +2 and +9 promotes electrostatic contact with negatively charged bacterial cell membranes. In addition to ensuring the capacity to insert into and disrupt membranes, the right ratio of hydrophobic to amphiphilic characteristics prevents aggregation, hemolytic activity, and non specificity brought on by high hydrophobicity. The peptide's length, which typically ranges from 10 to 30 amino acids, is also important. Protease stability, membrane interaction, and pharmacokinetics can all be enhanced by secondary structure and amino acid composition, particularly the presence of D- or unnatural amino acids. Together, these factors can be optimized to create antimicrobial peptides that are more effective and less harmful[22][23][24][25]

Synthetic Strategies for Peptides and Peptidomimetics

Solid-Phase Peptide Synthesis (SPPS)

Because of its great efficiency, repeatability, and automation-friendliness, Merrifield's solid phase peptide synthesis (SPPS) technique remains the standard for peptide and peptidomimetic synthesis. Because of its easy conditions and tolerance for different groups, the Fmoc-based approach is used to synthesize peptides via stepwise couplings and deprotections on a solid platform. Although the speed and quality of peptide synthesis have increased thanks to modern automated peptide synthesizers, there are still drawbacks such as low yield of lengthy and hydrophobic peptides, racemization, poor coupling efficiency, and peptide aggregation[26][27][28].

Solution-Phase and Hybrid Approaches

Despite being more complex than SPPS because purification procedures must be taken after each reaction, solution phase synthesis is nevertheless a useful technique for producing tiny peptides and peptide fragments with extremely high purity. To create longer and more complex peptides, a combination approach combines SPPS with solution-phase ligation techniques such as native chemical ligation (NCL) [29][30].

Microwave-Assisted and Green Synthesis

Microwave-assisted peptide synthesis speeds up coupling and deprotection reactions, which shortens reaction times while raising yield rates and reducing byproduct production. Environmentally friendly solvents, recyclable resins, solvent-free or minimal solvent procedures, enzyme catalysts, and flow chemistry are some of the ways that green chemistry approaches enhance sustainability [31][32][33].

Click Chemistry and Bio-Orthogonal Methods

The click reaction and bioorthogonal chemistry are two extremely effective and selective ways to modify peptides. While the SPAAC click reaction eliminates the need for hazardous copper catalysts and permits its application in biological systems, the CuAAC click reaction has been widely used for peptide coupling. Other instances of bioorthogonal processes include inverse electron-demand, Staudinger ligation, and oxime ligation. Diels-Alder chemistry enables the site-specific tagging of peptides with targeting moieties, medications, and fluorescent dyes [34][35][36].

Post-Synthetic Modifications

The biological activity of antimicrobial peptides have often been customized using post-synthetic modification techniques. While lipidation promotes affinity for the membrane surface and antibacterial activity, PEGylation results in enhanced circulation and lower immunogenicity, while cyclization increases stability and protease resistance. Peptide stability and delivery are also improved by other techniques like glycosylation and nanoparticle coupling [37][38][39].

Integrated Structure–Activity Relationship (SAR) Framework for Rational Peptide Design

Cationic charge, hydrophobicity, amphiphilicity, length of the peptide chain, and secondary structures are just a few of the physicochemical characteristics that work together to mediate the mechanism of action of antimicrobial peptides (AMPs) and peptidomimetics.While an excessive amount of positive charge can lead to greater cytotoxicity, the positive charge (+2 to +9) permits electrostatic contact with negatively charged bacterial membranes. While an overabundance of hydrophobic residues might result in hemolysis and non-selective contact with other membranes, hydrophobic and amphiphilic equilibrium leads to strong membrane recognition and destabilization. Because medium-length peptides provide the best balance between antibacterial effectiveness, chemical stability, and simplicity of production, peptide length is also important. In addition to increasing the molecule's affinity for the membrane and resistance to proteolysis, secondary structures such as α-helix, β-sheet, cyclic peptides, and peptidomimetic scaffold stabilize the molecule [40][41][42].

Mechanisms of Action

Membrane Disruption Models

The majority of antimicrobial peptides work by rupturing membranes. Because of their positive charges, they can readily interact electrostatically with the negative charges found in bacterial membranes, causing membrane permeabilization. Antimicrobial peptides have three primary modes of action: barrel stave, in which peptides create pores in transmembrane regions; toroidal pore, in which peptides and lipid heads form the lining of the pore; and carpet model, in which peptides build up on the membrane's surface and induce detergent-like membrane destruction [42][43][44].

Intracellular Targets

Certain AMPs and peptidomimetics can infiltrate bacterial cells and interfere with crucial intracellular processes in addition to rupturing membranes. Some of them could be inhibitors of cell wall construction, RNA transcription, DNA replication, protein synthesis, enzymes, or oxidative stress caused by ROS. Proline-rich AMPs, which inhibit bacterial ribosomes without altering their membranes, are well-known examples [45][46][47].

Immunomodulatory Effects

A growing amount of research indicates that many AMPs have immunomodulatory activities in addition to their intrinsic antimicrobial qualities. These include controlling the secretion of cytokines and chemokines, suppressing inflammation (for example, by blocking the NF-κB signaling pathway), attracting and activating leukocytes, and promoting wound healing through angiogenesis and tissue repair [48][49].

Multi-Target Mechanisms

AMPs can target numerous locations by breaking cell membranes, blocking their intracellular processes, and regulating immunity, in contrast to other antibiotic medications that primarily target one site. Peptidomimetics that are logically created for these combination actions improve stability, potency, and efficiency while lowering the risk of drug resistance [50].

Critical Comparison of Membrane-Dependent and Membrane-Independent Mechanisms

Antimicrobial peptides (AMPs) use both membrane-dependent and membrane-independent mechanisms, most of which work in concert. When it comes to membrane-dependent actions, the AMP works electrostatically on the negatively charged bacterial membranes prior to membrane insertion, pore creation, and membrane disruption, which results in quick cell lysis and decreased resistance to antimicrobial activity.On the other hand, in membrane-independent activities, the AMP is carried into the cytoplasm of the bacteria, where it influences the synthesis of DNA, RNA, and proteins, the activity of enzymes, the creation of cell walls, and oxidative stress caused by reactive oxygen species (ROS). Examples of these compounds that target bacterial ribosomes are proline-rich AMPs[15]. These pathways are supported by experimental data. While the intracellular mechanisms have been experimentally supported by DNA/RNA binding assays, ribosome binding assays, enzyme inhibition assays, ROS analysis, and transcriptional or proteomic studies, membrane disruption has been demonstrated through membrane permeabilization and depolarization assays, liposome leakage assays, and electron microscopy studies. In contrast to conventional antibiotics that target certain biological activities, these two strategies work in concert to make these compounds function as broad-spectrum antimicrobial agents with lower risks of resistance[51]

Pharmacological Evaluation

In Vitro Antimicrobial Assays

The initial step in identifying the antibacterial qualities of peptides and peptidomimetic substances is in vitro screening. The two primary metrics used to assess the antimicrobial efficacy against Gram-positive, Gram-negative, and fungal bacteria are minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC). The kinetics of bacterial cell lysis are ascertained by time kill tests, while the mode of action and toxicity are ascertained by hemolysis, permeabilization of the bacterial membrane, and mammalian cytotoxicity experiments [52][53][54].

In Vivo Models

To demonstrate the effectiveness and safety of the possible medication candidate, additional testing is conducted on animal models of infection, such as sepsis, cutaneous infection, lung infection, and biofilm development. The survival rate, bacterial load, inflammatory responses, histopathological alterations, and PK/PD parameters are significant factors. Despite the challenges related to costs, ethical issues, and interspecies differences, comparative studies with current antibacterials and combination therapies improve the therapeutic potential[55][56].

Traditional Chinese Medicine-Derived Antimicrobial Peptides and Their Translational Potential

TCM is a valuable source of biologically active natural compounds that could be the foundation for the development of peptide drugs. With a wide range of antibacterial and immunomodulatory qualities, peptides and bioinspired peptides such as jineol, Pseudin-2, and thanatin are interesting models for peptide engineering and design. Although TCM-derived peptides have greater structural variety than their conventional counterparts, they have low bioavailability, rapid cleavage, and poor metabolic stability. However, modern engineering techniques like cyclization, D-amino acid substitution for L-amino acids, PEGylation, and nanoparticle distribution can be used to

overcome these disadvantages. Therefore, peptides produced from TCM could be considered additional scaffolds for the generation of antimicrobial peptides [57][58].

Comparative Analysis of Natural Antimicrobial Peptides, Synthetic Peptides, and Peptidomimetics

The distinct characteristics of each type of antimicrobial medications—natural AMPs, synthetic peptides, and peptidomimetics—make their application beneficial in the creation of novel antimicrobial agents. Although they have a wide range of activity and immunomodulatory properties, natural AMPs have poor pharmacokinetics and stability. Although the sequence, specificity, and effectiveness of antimicrobial action can be rationally altered with synthetic peptides, they are vulnerable to enzyme degradation. Compared to other peptides, peptidomimetics have the advantage of avoiding the majority of the drawbacks of other peptide types, including poor membrane penetration, limited stability, and unfavorable pharmacokinetics. Peptidomimetics have the most potential among antimicrobial peptides, despite being more difficult to manufacture and control [59][60].

Safety, Toxicity, and Pharmacokinetics

Cytotoxicity and Hemolysis

Hemolytic activity and cytotoxicity are important factors in determining the toxicity and selectivity of AMPs. High cationic charge and hydrophobicity can raise the danger of mammalian cell toxicity, even though AMPs are known to operate selectively on microorganisms. Techniques such as rational peptide design by cyclization, hydrophobicity, and amino acid changes improve selectivity and reduce toxicity[61][62].

Stability and Degradation

However, proteolytic cleavage causes the majority of peptides to have low stability. Peptides' half-lives and metabolic stability are enhanced by cyclization, the use of D-amino acids, alteration at the ends of the peptides, pegylation, lipidation, and peptidomimetic approaches [63][64].

Immunogenicity

Peptides are less immunogenic than proteins, but regular administration can lead to the production of ADAs, which lowers the efficacy of the medication. This is accomplished by pegylation, substitution of D amino acids for L amino acids, sequence changes, and appropriate formulation techniques [65][66].

ADME Considerations

Rapid proteolysis, poor oral bioavailability, and renal clearance frequently limit peptide pharmacokinetics. Peptidomimetics, chemical changes, and nanocarrier-based delivery systems enhance tissue distribution, stability, absorption, and overall pharmacokinetic performance [67][68].

Bacterial Resistance to Antimicrobial Peptides and Rational Engineering Strategies

Although AMPs are more resistant to bacterial resistance than conventional antibiotics, bacteria use efflux pumps, biofilm formation, cell membrane modification, proteolytic enzyme release, and changes in cell membrane charge to counteract the effects of AMPs. Applying logical techniques like D-amino acid substitution, cyclization, peptidomimetics, charge and hydrophobicity adjustment, nanocarrier-mediated delivery, and a combination approach effectively improves the peptide's stability, boosts its antimicrobial potency, and lowers resistance[69].

Challenges in Large-Scale Industrial Manufacturing of Peptide Therapeutics

Large-scale manufacturing of antimicrobial peptides still confronts a number of challenges because of issues with scalability, purification, batch uniformity, and high production costs, despite notable advancements in the field of peptide synthesis. Even though SPPS is the conventional method of peptide synthesis, its low yield, inadequate coupling, and aggregation make it ineffective for the synthesis of lengthy and complex peptides. Although HPLC is a dependable and effective purification method, it is too expensive, requires a lot of solvents, and is difficult to scale up, making it a significant contributor to high manufacturing costs [70]. During the regulatory process, where

process validation, characterization, and control become effective, batch consistency becomes crucial. Additionally, the commercialization of peptides is hampered by the high cost of amino acids, reagents, purification, and GMP. These issues can be resolved and the next generation of peptide therapies developed with the aid of modern technologies like automated peptide synthesis, microwave-assisted synthesis, green chemistry, continuous purification, process analytical technology (PAT), and AI-assisted process optimization[71].

Peptide-Based Antimicrobials in TCM Context

Antibacterial peptides and peptide-inspired scaffolds with anti-inflammatory, immune modulatory, and antibacterial qualities are widely available in Traditional Chinese Medicine (TCM). The identification of these molecules with biological activity has been made easier by recent developments in the domains of proteomics, bioinformatics, and mass spectrometry. Significant challenges include inconsistent herbal resources, a lack of standardization, and an inadequate pharmacological profile. Novel antimicrobial drugs may be developed by combining TCM-derived peptide-inspired scaffolds with peptide design and synthetic chemistry[58][72][73].

Challenges Limiting the Clinical Translation of Antimicrobial Peptides

Despite encouraging results in pre-clinical research, few antimicrobial peptides (AMPs) have been used in clinical settings because of a multitude of obstacles, including scientific, pharmacokinetic, manufacturing, regulatory, and financial ones. The problems include cytotoxicity, rapid hydrolysis, low oral bioavailability, short half-life in plasma, and lack of action under physiological settings. Strict regulations, complicated purification, high manufacturing costs, and challenges in scaling up production are further problems. These obstacles would be overcome by innovative approaches in peptide design, nanostructure delivery, artificial intelligence-based design, sustainable production, and regulatory requirements[74].

Clinical and Translational Perspectives

Clinical Trials and Approved Peptide Drugs

The FDA has approved numerous other antibiotics, including Colistin, Polymyxin B, and Daptomycin, for the treatment of MDR bacterial infections. To find novel peptides with improved pharmacological, biophysical, and pharmacokinetic properties through peptide manipulation through genetic engineering and chemical changes, clinical studies are presently being conducted [75][76].

Challenges in Clinical Translation

Numerous challenges, including limited bioavailability, proteolysis, short half-life, cytotoxicity, immunogenicity, and costly manufacture, impede the therapeutic advancement of antimicrobial peptides. However, strategies like chemical modification and the creation of innovative drug delivery techniques have significantly improved the stability and efficacy of peptides[77].

Regulatory Considerations

Good production Practices, verified production processes, strict quality control standards, and comprehensive preclinical and clinical evaluations based on the specified regulatory requirements (e.g., FDA, EMA, and ICH) are all necessary for peptide therapeutic therapies. Clinical success still depends on manufactured standardization, batch homogeneity, pharmacovigilance, and post-market monitoring[78].

Integration of Artificial Intelligence with Experimental Validation for Antimicrobial Peptide Discovery

Through faster screening of peptide libraries, the prediction of antimicrobial efficacy, toxicity, stability, and pharmacokinetics, and quick lead optimization, developments in AI and ML have had a substantial impact on AMP research. However, these computational methods require experimental validation using peptide synthesis, MIC testing, hemolysis and cytotoxicity investigations, membrane penetration tests, pharmacokinetic evaluation, and in vivo infection models. AI models must incorporate experimental findings through iterative design-build-test-learn (DBTL) cycles. Despite their potential to transform AMP discovery, there are still issues with forecast inaccuracy,

poor explainability of the models, and bias in training datasets. Standardized training sets, AI, external model validation, and high throughput experiments will increase the reliability of AI-guided AMP discovery and accelerate the development of new antimicrobial therapies [79].

Translational Roadmap for Next-Generation Antimicrobial Peptide Therapeutics

AI, peptide engineering, bio-orthogonal chemistry, nanotechnology, and testing are all integrated in the translational development of AMPs. Peptide engineering improves stability, specificity, and pharmacokinetics, while AI facilitates quick screening and SAR investigations of AMP candidates. The potency of such candidates can also be increased by using nanocarrier-based delivery methods and bio-orthogonal chemistry. DBTL must be used to test optimized peptides employing in vivo infection models, pharmacokinetic research, and in vitro antimicrobial investigations. Last but not least, successful translation depends on GMP production, regulatory compliance, and clinical evaluation. This integrated method can offer helpful direction for the creation of AMP treatments that are usable in clinical settings.

Emerging Trends and Future Directions

Interdisciplinary advances in artificial intelligence (AI), nanotechnology, bio-orthogonal chemistry, and precision medicine are reshaping the development of antimicrobial peptides (AMPs) to address antimicrobial resistance (AMR).

AI-Driven Peptide Design

AI and machine learning enable rapid identification and optimization of AMPs by predicting antimicrobial activity, toxicity, stability, and structure–activity relationships (SAR), thereby accelerating lead discovery while reducing development time and cost [80][81].

Personalized Antimicrobial Therapy

Advances in genomics, proteomics, and precision diagnostics support the development of personalized peptide therapeutics tailored to pathogen characteristics and patient-specific factors, improving efficacy while minimizing off-target effects[82][83].

Nanocarrier-Based Delivery

Nanocarriers, including liposomes, polymeric nanoparticles, dendrimers, and lipid nanoparticles, enhance peptide stability, bioavailability, targeted delivery, and controlled release, thereby improving therapeutic efficacy [84][85].

Bio-Orthogonal In Vivo Applications

Bio-orthogonal reactions, such as strain-promoted azide–alkyne cycloaddition (SPAAC) and inverse electron-demand Diels–Alder chemistry, enable site-specific peptide labeling, activation, and targeted delivery under physiological conditions, facilitating precision antimicrobial therapy. Overall, integrating AI, peptide engineering, nanotechnology, and bio-orthogonal chemistry is expected to accelerate the discovery, optimization, and clinical translation of next-generation antimicrobial peptide therapeutics [86][87][88].

CONCLUSION

When treating AMR, AMPs and peptidomimetics may be useful alternatives to conventional antibiotics. Peptide design and functionalization can be enhanced by the advancement of peptide chemistry and synthesis technologies such as solid-phase peptide synthesis (SPPS), microwave-assisted synthesis, click chemistry, and bio-orthogonal techniques. Because of their methods of action, which include intracellular activity, immunomodulation, and cell membrane rupture, peptides exhibit a wide range of effects. Therefore, it is unlikely that peptides would have the same issues related to the emergence of AMR. However, there are still several issues with these peptides' instability, toxicity, pharmacokinetics, manufacturing method, and clinical application. Researchers were able to enhance the

drug-like properties of peptides with the aid of peptide engineering and nanotechnology in delivery systems and appropriate formulation. Furthermore, peptides with antibacterial properties can be created using the framework of peptides from traditional Chinese medicine. The application of artificial intelligence in peptide design, bio-orthogonal chemistry, nanotechnology, and interdisciplinary experiments will be linked to the next stage of peptide research.

Table 1: Classification and Structural Features of Peptide and Peptidomimetic

Class	Motif Sequence	Net Charge (pH 7.4)	Hydrophobicity Index (%	Secondary Structure	Key Structural Modifications	Primary Mechanism of Action	Spectrum of Activity	Limitations
Natural AMPs (α-helical)	Magainin	+4 to +6	40–50%	α-helix	C-terminal amidation	Disruption of membranes	Gram+, Gram−, and Fungi	Moderate toxicity and proteolytic instability
Natural AMPs (β-sheet)	Defensins (Cys-rich peptides)	+3 to +7	30–40%	β-sheet	Disulfide bridge formation	Membrane permeabilization	Gram+ / Gram− / Virus	Complex synthesis, stability issues
Extended AMPs	Indolicidin (Trp-rich)	+4	45–55%	Random coil	Trp-rich motif	DNA binding + membrane disruption	Gram+ / Gram− / Fungi	Cytotoxicity, hemolysis
Synthetic Linear Peptides	Designed Lys-Leu-rich sequences	+5 to +9	45–60%	α-helix	Sequence truncation, substitution	Membrane lysis	Broad spectrum	Toxicity at high doses

ABSTRACT

Sun drying is considered the least expensive and efficient food preservation methods in Tamil Nadu and the product plays an important role particularly in providing nutrition to the poor and economically disadvantaged people, especially in remote areas with few rainfall and seasonal water streams. The prime objective of this study is to analyze the nutritional, microbial, sensory and heavy metals content of sun and turmeric treated dried *S. guttatus* collected from local fish market at Rameswaram. The dried fish products available in the markets of Rameswaram were found to have high nutritional value. Both the dried samples of *S. guttatus* were found to have overall acceptability score in the range of 8.86 and 9. The sensory evaluation of the both the samples revealed that maximum overall acceptable quality. After one year of storage dried samples were found to have decline in overall acceptability score. The highest TVC was recorded in sun dried samples (4.2×10^3) and the lowest value was recorded in turmeric treated dried samples (4.0×10^3) and after one year of storage the highest TVC was 16×10^3 while lowest was 14×10^3 respectively. Though the absence of *E.coli* and Salmonella species was a good sign for consumers, the presence of S. aureus in the product indicates slight unhygienic handling during processing and storage.

Keywords: *Scomberomorous guttatus,* Dried Fish, Nutritional quality, Microbial quality and Sensory Quality

INTRODUCTION

Dried fish is one of the traditionally preserved foods. Dry fish is an essential source of animal protein supplement, which is preferred as a key dish or used as a flavoring agent in combination with other food items. One hundred

grams of dried fish contains about 80% protein with 300 calories. This profile makes dried fish a compelling purchase for those looking to increase their intake of healthy food and provides a distinct advantage of dried fish retailers. As per the recent report published by Marine Product Export Development Authority, more than Rs.2852.60 crore worth dried items exported to various part of the world (MPEDA, 2025). The consumption of dried fishes is about 32% of the total marine landings in India and this ranks second to fresh fish consumption. Dry fish is also a very favorite food item among people and has a good market demand besides fish and seafood products. It has a storage life for several years and it is consumed all over the world for its nutritional value, taste and aroma. Dried fishes are healthy white meats with low levels of cholesterol so it is recommended for complete and comprehensive diets of diabetes and obesity people. Pure dried fish is a completely natural product that retains the antioxidant and omega-3 benefits of fresh fish, while constituting a healthy and widely available food for people. It helps to mitigate the occurrence of heart attacks and keeps the body's circulation functioning well. These benefits provide key marketing tools that can make dried fish retailing a profitable business (Rimm, 2016).

Spoilage proceeds as a series of complex enzymatic, bacterial and chemical changes that start in some few hours after fish being caught depending on the species and the prevailing ambient temperature. This may render it unacceptable and unfit for human consumption. Plenty of fish is available during the fishing season when the fishermen for want of speedy transport facilities cannot send to the market for sale. Thus, the fishermen either have to sell their catch at a cheaper rate or they have to let their catch go waste due to lack of proper processing and strong facilities. If the bulk could be processed or preserved for short term or long-term period and stored successfully the requirement of the off season would have been met up to a significant extent. Proper preservation starts the moment it is harvested until reaches the consumer's table (Oluborode *et al*., 2010). Traditionally, fishermen often resort to salting and drying in order to preserve and save surplus fish harvested during peak harvest seasons for use during off seasons. In addition, some high value products such as shark fin fish, seer fishes and fillets are dried for export markets (Al-Ghabshi *et al*., 2012). Efforts should therefore, be geared towards increased fish production through improved resource management matched with effective postharvest handling, preservation and processing to prevent spoilage. Consequently, research is needed to improve their shelf life and nutritional values in traditional preservation techniques, so in the peak harvesting periods, these fish could preserve properly to serve in lean periods as a cheap and immediate source of animal protein to all classes people (Latifa *et al*., 2014).

The salting process is considered as one of the oldest method of fish preservation and this process is still being used in several places around the world. Salted fish products are popular in many countries and it has been proved to be safe for the millenniums even in developed countries (Turan *et al*., 2007). Salting is generally aimed at reducing water activity (aw) which inhibits the growth of spoilage microorganism as well as to inactivate autolytic enzymes (Ashie *et al*., 1996). The aim of salting is not only to extend the shelf life of fresh fish but also to provide desirable sensorial changes (Andres *et al*., 2005). The quality of salted and sun dried fishes are adversely affected by the occurrence of microorganisms. Determination of microbiological quality of such processed fishes from the market is very important for guarding consumer's health and hygiene (Lilabati *et al*., 1999). The spoilage of dried fish is mainly due to bacterial, fungal or yeast action, rancidity, autolysis, browning and other reactions, all of which are temperature and water activity dependent (Doe, 1982). The fish usually takes 5 to 7 days to dry during which it gets heavily contaminated. High levels of metals have been to cause rapid physiological changes in fish (Tarrio *et al*., 1991). These toxic wastes are usually industrial wastes, sewage, pesticides and heavy metals such as Mercury and Cadmium. The pollutants especially Mercury could possibly end up in human bodies due to the consumption of affected fish (Atuanya and Okoro, 2007). There is increasing concern about the quality of foods in several parts of the world; the determination of toxic elements in processed food has prompted studies on toxicological effects of them in food (Khansari *et al*., 2005). The risk associated with the exposure to heavy metals present in dried fish products had aroused widespread concern in human health. Improvements in the food production and processing technology had increased the chances of contamination of food with various environmental pollutants, especially heavy metals (Santhi *et al*., 2008).

The proximate composition is an important aspect of dried fish quality and it influences both the keeping quality and technological characteristics of the fish. The main chemical components such as water, crude protein, lipid and ash have the largest impact on the nutritive value, the functional properties, and the sensory quality and storage ability of flesh. Therefore, information on the nutritive value and its food quality are equally important regarding the proper utilization of products (Flowra and Tumpa, 2012). But nutritional composition varied in large scale in different dried fish product. Hence, it is necessary to ensure the nutritional value as well as quality of the dried fish products. Now a days various herbal preservatives are used in drying process and to improve the quality of dried fish. Use of herbal preservatives such as turmeric powder is most commonly used in India. Turmeric powder act as a repelling effect of beetles and mites associated with dried fish (Akter *et al*., 2013). In tropical area of Rameswaram, apart from the fresh fish some quantity of the fishes used for salting and sun drying and used as a dried fish in local and export market. The study was aimed at understanding the safety of dried fish products after the drying process and to identify the microorganisms that contaminate dried fish and made appropriate recommendations for mitigation.

Prakash *et al*., (2011) determined the microbial quality of six sundried seafood species available in Tuticorin dry fish market, South East Coast of India. An analysis of biochemical with minerals composition of three different fish species by drying methods (*Bonga* species, *Sardinella* species and *O. niloticus*) was done by Priya *et al*., (2011). Saritha *et al*., (2012) carried out a study on microbial and biochemical qualities of seven salted and sun dried sea foods of Cuddalore, South East Coast of India. Quality and safety aspects of three sun dried marine fish species Chinese pomfret (*Stromateus chinensis*), Bombay duck (*H. nehereus*) and ribbon fish (*Trichiurus haumela*) was discussed by Pravakar *et al*., (2013). Latifa *et al*., (2014) evaluated the shelf life quality of salt and turmeric treated fishes, chapila (*G. chapra*), Kaika (*Xenentodon cancila*), Guchi Baim (*Mastacembelus pancalus*) and also analyzed the biochemical composition and sensory evaluation during storage at refrigeration temperature. Igwegbe *et al*., (2014) evaluated the effects of season and a fish preservation process namely salting and sun drying (using a solar tent dryer) on the levels of Lead, Cadmium, Mercury and Arsenic in the fresh and processed fish species, *Tilapia nilotica*, *Synodontis guentheri*, *H. niloticus* and *C. anguillaris*. Influence of drying processing on nutritional properties of three fish species Govazym stranded tail, Hamoor and Zeminkan was observed by Aberoumand and Abad (2015). Bhuyan (2016) studied some indigenous fish preservation techniques practiced in Jorhat District, Assam, India. Sahu *et al*., (2018) reviewed the economics of fish drying in Digha Mohana Khuti, West Bengal, India. Nutritional and microbial quality of dried nile bulti *Oreochromis niloticus* (Trewavas) tested by Ali *et al*., (2021) and proximate composition, microbiological quality and safety of raw and open sun-dried fish products in Lake Tana, Ethiopia reported by Birie *et al*., (2025). With this background, the present investigation was designed to carried out in order to assess the nutritional, microbial, sensory and heavy metals content of sun and turmeric treated dried *S. guttatus* collected from local fish market at Rameswaram., Tamil Nadu, South India.

MATERIALS AND METHODS

Sample collection

The experimental samples of sun dried and turmeric treated dried fish (Local name: Pattara karuvadu) of *S. guttatus* were collected from local fish market at Thangachimadam in Rameswaram Island. The collected samples were taken to the laboratory in an airtight glass container and stored at room temperature for subsequent studies. The analyses were carried out in triplicates of each sample of dried fish.

Sample preparation

Sun dried fish: The fishes were washed in the sea water and immersed in salt water solution for 24 hours and dried for 2 - 4 days on a sea shore sandy area or on palm leaves under the direct sun. The ratio of salt used for salting of fish is too low to ensure adequate preservation.

Turmeric treated dried fish (Pattara karuvadu)

The fishes were washed in the sea water and split longitudinally, after that they were removed and cleaned properly. The fishes were filled with salt and dumped inside the sand for 7 days. After 7 days the fishes were removed from the sand and coated with turmeric powder. Both the dry samples were taken accurately and each sample was crushed with mortar and pestle. The samples were analyzed for physicochemical composition, proximate composition, microbial and heavy metals content.

Biochemical and Microbial analysis of dried fish:

pH value, protein, carbohydrate, lipid and ash contents of the dry fish samples were measured by following the method of AOAC (2005). For microbial analysis one gram (1g) of dry fish sample was dissolved in sterile deionized water and serially diluted. One milliliter (1ml) of appropriate dilutions was seeded on plate count agar using spread plate method, and the medium was then incubated at 37°C for 24 hours. The plate count agar was examined and colonies present were counted and recorded after incubation at 37°C for 24 hours to get the total colony count in Cfu/g (Obi and Krakowiakass, 1983). Amine forming bacteria and fungus species were isolated using suitable agar medium (Surendran *et al*., 2006).

Sensory analysis of dried fish

Appearance, colour, flavour, odour, texture and the overall acceptability of the dried fishes were evaluated using 9 point grading scales. The panelist was requested to rate each sensory features of the selected dried fishes. The average score of 5 was considered to be the borderline of acceptability (9 - like extremely; 8 - like very much; 7 - like moderately; 6 - like slightly; < 5 bad).

Heavy metal analysis of dried fish:

Sample preparation and heavy metal analysis

Accumulation of metals such as Mercury, Lead, Cadmium and Chromium were estimated in both the dried samples of *S. guttatus*. The dried fish samples were crushed and powdered in a mortar and pestle. The samples were digested in concentrated nitric acid and sulphuric acid (4:1) till all the material gets dissolved. It was then filtered through Whatman No.1 filter paper and then washed with distilled water and collected in a 50 ml volumetric flask. The digested samples of muscles from *S. guttatus* were then poured into an auto analyzer cups and concentration of heavy metals (Mercury, Lead, Cadmium and Chromium) in each sample was determined using Atomic Absorption Spectrophotometer (AAS). The values of heavy metal concentrations in the tissues were calculated based on dry weights as this discounts the variability due to inner parts differences in the moisture content of organisms.

Analysis after storage period

The samples of dried *S. guttatus* collected from local fish market at Thangachimadam in Rameswaram Island were packed in an airtight glass container and stored at refrigerator temperature for the period of twelve months. The physicochemical, biochemical, microbial and sensory characteristics of sun and turmeric treated *S. guttatus* were analyzed after storage period. The analyses were carried out in triplicates of each sample of dried fish.

Statistical analysis:

The biochemical composition analysis was conducted in triplicates from three independent experiments conducted for the study. Results were expressed as mean values ± Standard deviation (SD). The difference between the sand and turmeric treated *S. guttatus* were calculated using paired 't' test and statistically significant difference were reported at $p<0.05$.

RESULTS

Biochemical, microbial, heavy metal and organoleptic analysis were done in sun dried and turmeric treated sand dried samples of *S. guttatus*. The performance of salt and turmeric treatment against insect infestation and storage

conditions were observed using airtight containers. The drying time was shorter in sundried compared to the turmeric treated sand dried samples. Increase in temperature resulted in shorter drying time. The drying time was five days in sun dried and seven days in turmeric treated sand drying method.

Biochemical composition of dried sample

The moisture content of the sun and turmeric treated sand dried samples of *S. guttatus was* in the range of 9.2 ± 0.2 to 10.1 ± 0.15%. The highest moisture content was recorded in sun dried sample (10.1 ± 0.15%) and the lowest (9.2 ± 0.2%) was in turmeric treated sand dried sample. The protein content of sun and turmeric treated sand dried *S. guttatus* ranged from 32.5 ± 0.07 to 35.7 ± 0.1%. Highest protein content was observed in turmeric treated samples (35.7 ± 0.1%), while lowest in sun dried (32.5 ± 0.07%) samples. Lipid content was ranged from 0.51 ± 0.022 to 0.59 ± 0.01%. The highest lipid content was found in sun dried (0.59 ± 0.01%) samples and lowest in turmeric treated dried (0.51 ± 0.022%) samples. Similarly highest carbohydrate content (5.5 ± 0.022%) was observed in turmeric treated samples and lowest (5.2 ± 0.2%) in sun dried samples. The highest ash content was found in sun dried samples (20.8 ± 0.12%) and lowest in turmeric treated dried (19.7 ± 0.21) samples. pH value is a reliable indicator of the degree of freshness or spoilage. The highest pH was observed in turmeric treated dried samples (6.88 ± 0.01) and the lowest value was observed in sun dried samples (6.79 ± 0.01).

Biochemical changes of dried samples after storage period

After one year of storage the moisture content was 71.5 ± 0.05% and 68.9 ± 0.07% in sun and turmeric treated sand dried samples. The maximum protein content was recorded in turmeric treated samples (19.2 ± 0.1%) and lowest in sun dried samples (16.5 ± 0.23%). Highest carbohydrate content recorded in turmeric treated dried (4.2 ± 0.26%) and lowest value was recorded in sun dried samples (3.9 ± 0.17%). Highest lipid and ash contents were recorded in sun dried samples (0.39 ± 0.012% and 2.2 ± 0.21%), while lowest values were recorded in turmeric treated sand dried samples (0.37 ± 0.01% and 1.98 ± 0.03%). The highest pH value was observed in turmeric treated dried samples (5.89 ± 0.01) and lowest value observed in sun dried samples (5.79 ± 0.01%) after one year storage in airtight containers.

Microbial analysis of dried samples before and after storage

The number of bacteria in foods serves as a general indicator of hygiene. Determination of total bacterial count is widely used to assess the bacterial quality of fish. The limit for TVC is 1×10^5 Cfu/g in dried products. The highest TVC was recorded in the sun dried samples (4.2×10^3 Cfu/ g) and the lowest value was recorded in turmeric treated sand dried samples (4.0×10^3 Cfu/ g). After one year of storage period, the highest TVC (16×10^3 Cfu/ g) was recorded in sun dried samples and the lowest (14×103 Cfu/ g) was in turmeric treated sand dried samples The susceptible distribution of bacterial and fungal species presents in both the dried samples of *S. guttatus* were *E. coli, K. pneumonia, S. aureus, P. vulgaris, P. aeruginosa* and *S. typhimurium*. The distributions of fungal species present in the *S. guttatus* were *A. niger, M. canis* and *F. oxysporum*. *E. coli* and *S. aureus* were isolated from the sun dried samples. In turmeric treated dried samples *S. aureus* were isolated. Other bacterial species were not detected in sun and turmeric treated dried samples. After one year of storage *E. coli*, *S. aureus* and *A. niger* were isolated from sun dried samples, in turmeric treated sample *S. aureus* were isolated.

Sensory analysis of dried samples before and after storage

The mean score obtained for sensory analysis, which emphasizes colour, appearance, flavour, odour, mouth feel, texture and overall acceptability are tabulated. The products of sun and turmeric treated dried samples were found to have overall acceptability score in the range of 8.68 to 9.0. After one year of storage the sun and turmeric treated dried samples of the scores for appearance, colour, flavour, odour, mouth feel, texture, and overall acceptability were declined and the scores were declined from 4.71, 5.14, 5.28, 5.14, 5.0, 5.28 and 5.0 in sun dried sample and 5.14, 6.0, 6.5, 6.0, 6.2, 6.0 and 6.5 in turmeric treated dried samples respectively.

Heavy metal analysis in dried samples

Accumulation of heavy metal contents Mercury, Lead, Chromium and Cadmium of sun and turmeric treated dried samples were well below the detectable limit (BDL). There is no metal accumulation in both the dried samples.

DISCUSSION

Being one of the richest sources of protein, vitamins and minerals fishes are widely used as essential source of nutrients required for people. But the availability of this valuable nutrients source largely depends on the extent of salting, drying, smoking and freezing and may other types of preservation methods (Farid *et al*., 2014). There are unsuitable maintenance techniques which make problems for access to its protein. Drying process is a treatment for maintenance of fish and other animal proteins, because its quality is preserved for long time period and little changes and lost minimum in production. Moisture plays an important role in the spoilage of fish and fish products and thereby reducing the level of moisture retards spoilage. In this study, the sun dried samples were treated with salt and turmeric treated dried samples treated with the combination of salt and turmeric. The salt treated sun dried *S. guttatus* was observed to have highest moisture content, irrespective with lowest protein, lipid and ash contents. High value of moisture content of the products studied might be due to absorption of moisture during storage and marketing. This finding was similar to the results obtained by Prodhan *et al*., (2010) evident that, with the increase of storage period moisture content increased in the samples of *S. guttatus* (15.88 ± 1.91 to 17.8 ± 3.12%). While working with S. fimbriata, Immaculate *et al*., (2012) found that naturally and hygienically sundried, using solar dryer and fishy rack moisture content were 11.60%, 8.3% and 4.0% respectively. Mansur *et al*., (2013) reported that moisture content of dried Indian major carps ranged from 19.17 to 23.99%. The present results of sun and turmeric treated dried products of *S. guttatus* was also agreed with the above studies. The moisture content of sun and turmeric treated dried *S. guttatus* from Rameswaram market (9.2 ± 0.2 to 10.1 ± 0.15%) was within the acceptable levels specified by MPEDA. The samples collected from the local market in Rameswaram have acceptable level of moisture content. It may be due to quality of raw fish, proper drying and maintenance and good storage facility.

Protein is essential for the sustenance of life and exists in largest quantity of all nutrients as a component of the human body (Okuzumi and Fujii, 2000). It is desirable to have a high percentage of protein in food products which is an important factor in case of quality analysis. Protein decreased with storage of cured meat was attributed to some changes during storage that caused by Maillard reaction and changes in pH (Lawrie, 1990). Salt causes the proteins in fish muscle to swell and salt lead the protein become denatured if increases in the muscle (Hamm, 1994). A significant increase in the amount of protein in dried fishes indicates that fish protein nitrogen in drying period is not going to lose. The protein content varied significantly ($p<0.05$) between the samples and the values were 35.7 ± 0.1% in turmeric treated and 32.5 ± 0.07% in sun dried samples of *S. guttatus*. Generally, dried fishes showed the highest protein content then compared to the fresh fishes. It may be the result of dehydration of water molecules present between the proteins thereby causing aggregation of protein and thus resulted in the increase in protein content of dried fishes. This result was also in agreement with the finding of Sankar *et al*., (2013). Ogbonnaya and Shaba (2009) observed that protein nitrogen was not lost during drying, so the protein content increased with the reduced moisture content in the fish samples. Flowra and Tumpa (2012) found that protein content of selected dried fishes varied from 28.20% (*W. attu*) to 51.19% (*Palaemon* species). Lipids are the major sources of metabolic energy and essential materials for the formation of cell and tissue membrane (Sargent, 1995). Lipid content may be influenced by season and geographic condition (Agren, 1991).

The carbohydrate content was relatively low ($p < 0.05$) when compared to the protein content of the samples. Major function of carbohydrate is production of energy for body cells, for accumulation and shrinkage of some food molecules and many of the 93 physiological functions needs carbohydrate. Aberoumand and Abad (2015) reported that carbohydrate content of three fish species (Govazym stranded tail, Hamoor and Zeminkan) varied from 77.44 ± 0.26 to 85.66 ± 0.26%. Ash content is generally influenced by size of fish. Smaller sized fish species tend to have higher

ash content due to the higher bone to flesh ratio (Daramola *et al*., 2007). Generally, in the fresh fishes, the ash content was very low, and dried fishes have higher ash contents. The ash content varied significantly between the samples and the values were 20.8 ± 0.12% in sundried and 19.7 ± 0.21% in turmeric treated dried samples of *S. guttatus*. Clucas and Ward (1996) reported that inorganic contents remain as ash after the organic matter is removed by incineration. Natural sun drying was done in open space which allows settling of windborne dust, insect and bird infestation. It would increase the inorganic contents in the samples and this may be the major reasons for higher ash content in sun dried samples. In sand drying method the samples were dried under the sand so there is no insect infestation, wind borne dust, this may be the reason for lower ash content in sand dried samples. Ash content reflects fair degree of importance of a species as a source of minerals and our present findings are in agreement with other reported values. Flowra *et al*., (2012) reported that the ash content in dried fishes ranged between 9 to 30% on the basis of moisture and dry matter contents. Patterson *et al*., (2018) reported that ash content of the dried fish *S. commersonnii* was varied from 0.65 ± 0.83 to 0.72 ± 1.74% in different drying method. Similar work was done by Longwe and Kapute (2016), who reported that ash content of the *O. karongae* varied from 20.00 ± 0.00 to 21 ± 1.07% and Azam *et al*., (2013) reported that 5.08 to 16.02% of ash content in four dried fishes.

pH value varied significantly between the samples and the values were 6.79 ± 0.01 in sundried and 6.88 ± 0.01 in turmeric treated sand dried samples of *S. guttatus*. The conventional air drying at a relatively higher temperature is determined to fish muscle and resulting in changes in pH, which affect solubility and water binding properties (Zyas, 1997). Decomposition of nitrogenous compounds often tends to increase in pH level in fish flesh in the post mortem period. Farid *et al*., (2014b) found that pH ranges varied from 6.9 to 7 in the shoal fish (*C. Striatus*) and taki fish (*C. Punctatus*). All the biochemical parameters of turmeric 94 treated dried fish samples showed significant values ($p < 0.05$) when compared to sundried samples. Fish is a reservoir of large number of microorganisms. One of the major factors contributing to poor quality of the fish in retail trade is unhygienic handling and storage leading to the smell, physical damage and contamination with dirt and objectionable microorganisms (Sugumar *et al*., 2004). Bacterial spoilage is characterized by softening of the muscle tissue and the production of slime and offensive odours. Low level of TVC was found in turmeric treated sand dried sample (4.0×103 Cfu/g) at the initial period; this may be attributed to low moisture content. High moisture content may be the reason for high level of TVC in sun dried samples (4.2×103 Cfu/g). Saritha *et al*., (2012) found that the higher bacterial count in dried *Parupeneus indicus* (2.13×106 Cfu/g). Prakash *et al*., (2011) reported that *S. fimbriata* collected from Tuticorin market had the highest bacterial count (5.7×104 Cfu/g) and Logesh *et al*., (2012) also found that highest total plate count of *S. longiceps* collected from Parangipettai (5.3×106 Cfu g-1) and lowest in Pudukuppam (3.2×106 Cfu g-1), Tamil Nadu. Majumdar and Rashid (2017) found that the total plate count of dry salted Hilsa, *T. ilisha* collected from different retail markets ranged from 5.75 ± 0.35×106 Cfu/g to 8.74 ± 0.39×107 Cfu/g.

The results of the study revealed that *S. aureus* were the common pathogenic bacteria found associated with sun and turmeric treated dried *S. guttatus* may be due to the contamination of the fish samples by man through handling and processing. *S. aureus* is a natural microflora of fish and shellfish (Clucas and Ward, 1996). Its main habitat is humans and animals, and found mostly in the nose, throat and skin of healthy individuals. This indicates that dried fish with these bacterial pathogens, must have been contaminated the dried fish through human handlers, air and soil. The contamination with *Staphylococcus* can be prevented by adequate control over the health and hygiene of fish handlers. The present results were in parrellel with Udochukwu *et al*., (2016), who observed that the *S. aureus* in some fresh and smoked fishes sold in Benin City. The quality of the dried fish is often adversely affected by the growth of fungi (Chakrabarti and Verma, 1997) and substantial amounts of fish are discarded during drying due to fungal growth (Gupta and Samuel, 1985). At the initial stage the dried fish samples of the present study were free from visible fungal colonies but after one year of storage of dried sample, plating on potato dextrose agar revealed presence of fungi (1×101 Cfu/g) in sun dried sample of *S. guttatus*. For consumers, the perceivable sensory attributes of colour, appearance, flavour, odour, mouth feel, texture and overall acceptability are the deciding factors in food acceptance. The sensory evaluation of the product helps in ensuring that the consumers get consistent, non-defective and enjoyable foods (Pal *et al*., 1995). The ultimate measure of quality is consumer acceptance and hence sensory quality of the product plays a major role in determining the quality of dried products. The difference in the sensory quality

and overall acceptability of the product might be attributed to the different degree of biochemical and microbiological changes in the dried fish may have undergone during drying and subsequent storage. Turmeric treated dried sample of *S. guttatus* were liked by panellist and the obtained overall acceptability score was 9.0 point from grading scales and sun dried sample have the overall acceptability of 8.86 ± 0.26 from the 9.0 point grading scales. Both sun and turmeric treated dried fishes were having the appearance of freshly dried, the texture was firm, colour was good and bright, odour was absent. The initial scores of sun dried samples were 8.85, 8.71, 9.0, 8.71, 9.0, 8.29 and 8.86 respectively and the initial scores of turmeric treated sand dried samples for appearance, colour, flavour, odour, mouth feel, texture, overall acceptability were 9.0, 9.0, 8.78, 8.86, 9.0, 8.57 and 9.0 respectively. Both the sun and turmeric treated dried products was rated as "good" based on the overall acceptability.

Many countries are now taking voluntary or mandatory action to reduce pollution of the aquatic environment with heavy metal for the food safety of aquatic food particularly fish. Considering the effect of heavy metal on fish quality and safety the food regulatory and health authorities in some developed countries have taken serious view and adopted maximum allowable limit of harmful metals and elements usually the pollutants of metals and element category contaminate the raw fish. Accumulation of heavy metals content of sun and turmeric treated dried samples of *S. guttatus* were well below the detectable limit (BDL). There is no metal accumulation in the dried sample of *S. guttatus* collected from the Thangachimadam market, Rameswaram. This information is very important for the domestic consumers in Rameswaram as well as for international markets where dried fishes are exported. The initial moisture contents observed in sun and turmeric treated sand dried samples were 10.1 ± 0.15% and 9.2 ± 0.2% respectively and after one year of storage the moisture contents were 71.5 ± 0.05% and 68.9 ± 0.07% respectively. High value of the moisture content of the products during storage might be due to absorption of moisture content in storage period. The mean percentage of moisture content was increased due to increasing of storing period.

The initial protein content observed in sun and turmeric treated dried samples were 32.5 ± 0.07% and 35.7 ± 0.1% respectively. After one year of storage, the protein contents were 16.5 ± 0.23% and 19.2 ± 0.1%, which was relatively low when comparing to the initial level. The protein digestibility is adversely affected by the dehydration and storage of dried fish products (Raghunath *et al*., 1995). The species of fish, freshness of the raw material prior to drying and the drying method could influence the reactions that read to a reduction in the biological value of fish protein (Opstve *et al*., 1988). The initial lipid content recorded in sun and turmeric treated dried samples were 0.59 ± 0.01% and 0.51 ± 0.022% and after one year of storage the lipid contents were decreased to 0.39 ± 0.012% and 0.37 ± 0.01%. The results showed that the lipid content decreased during storage period, it may be due to the moisture gain in both sun and turmeric treated dried samples. Prodhan *et al*., (2010) reported that during storage period (12 months) the lipid content was gradually deceased in the samples of *S. guttatus* 7.2 ± 0.5% to 6.0%. Carbohydrate level in the analyzed samples varied from 5.2 ± 0.2 to 3.9 ± 0.17% and 5.5 ± 0.022 to 4.2 ± 0.26% during storage time. Siddique and Aktar, (2011) observed that the carbohydrate content of three marine dried fishes (*H. nehereus, J. dussumieri* and *L. savala*) was varied from 4.11 - 2.41%; 2.94 - 1.13% and 1.64 - 0.08% respectively during the storage period which was similar to our present findings. In the present study, ash level in the analyzed sun and turmeric treated dried samples of *S. guttatus* were varied from 20.8 ± 0.12 - 2.2 ± 0.21% and 19.7 ± 0.21 - 1.98 ± 0.03% during the storage period. Mansure *et al*., (2013) found that the ash content in the range of 11.11 - 18.89% in three dried fishes. The initial pH content recorded in sun and turmeric treated dried *S. guttatus* were 6.79 ± 0.01 to 6.88 ± 0.01 respectively, after one year of storage the pH content was 5.79 ± 0.01 to 5.89 ± 0.01.

The highest TVC was recorded in sun dried samples of *S. guttatus* (16×103 Cfu/g) while lowest values were recorded in turmeric treated dried samples (14 $\times 10^3$ Cfu/g). In the present study during storage TVC in both the samples increased due to increase in moisture content. A similar trend was observed by Relekar *et al*., (2014) during the storage of dried *L. savala*. Similarly, Kakati *et al*., (2017) reported that total viable count range (3.2 to 4.1 log Cfu/g) of six selected dried fishes in Assam, India. Imtiaz *et al*., (2017) also found that the lowest bacterial load of 2.1×10^5 Cfu/g in turmeric treated sample of *T. haumela*, followed by 2.4×10^5 Cfu/g in salted samples and the highest value of 3.0×10^5 Cfu/g in control samples within seven days storage. After one year of storage the scores for appearance, colour, flavour, odour, mouth feel, texture and overall acceptability of sun and turmeric treated dried samples declined and

the scores were from 4.71, 5.14, 5.28, 5.14, 5.0, 5.28 and 5.0 in sun dried samples and 5.14, 6.0, 6.5, 6.0, 6.2, 6.0 and 6.5 in turmeric treated dried samples. The sun dried samples were appearing stale with firm texture, slight fishy odour, slight discolouration were occurred and rated as „slightly poor" and turmeric treated dried samples were rated as „moderately good" after a storage period of one year based on the overall acceptability.

CONCLUSION

Fish is a favorite foodstuff for the majority of societies. Fish has been recognized as an excellent food source for human beings for centuries and is preferred as a perfect diet not only due to its excellent taste and high digestibility but also because of having higher proportions of unsaturated fatty acids, essential amino acids and minerals for the formation of functional and structural proteins. Body composition is a good indicator of the physiological condition of a fish but it is relatively time consuming to measure. Proximate body composition is mainly the analysis of moisture, fat, protein and ash contents of fish. Both the dried fish products available in the markets of Rameswaram were found to have high nutritional content. The sensory evaluation of the dried products of sun and turmeric treated sand dried *S. guttatus* revealed that maximum overall acceptability quality. Microbial quality of both the dried products were acceptable limit. Though the absence of *E.coli* and *Salmonella* species was a good sign for consumers, the presence of *S. aureus* in the product indicates slight unhygienic handling during processing and storage. Therefore, care should be taken for hygienic measure right from the preparation of raw materials, use of utensils, handling practices, processing methods and during storage, in order to safeguard the health of the consumers. Packing may also be important for better keeping and increasing shelf life of the products. Heavy metals (Mercury, Lead, Chromium and Cadmium) accumulations in dried samples were found below the detectable limit. There is no heavy metal accumulation in dried samples collected from Thangachimadam, Rameswaram Island.

ABSTRACT

Generalized Anxiety Disorder (GAD) is a prevalent psychiatric condition marked by persistent, excessive anxiety with cognitive, emotional, and somatic symptoms. Despite advances in standard treatments, challenges like adherence, adverse effects, chronicity, and individual variability persist. Individualized therapeutic approaches based on constitutional and temperamental assessment may offer a new framework for understanding the diversity in anxiety presentations. This study investigates temperament-based constitutional prescribing in GAD patients receiving individualized homoeopathic treatment. A prospective observational clinical correlation study was conducted between January 2021 and March 2023 at the Parul Institute of Homoeopathy, Parul University, India. 100 patients with GAD (DSM-5 criteria, GAD-7 scale) were enrolled; 97 completed the study. Each underwent individualized homoeopathic case analysis, constitutional prescription, and 4–6 follow-up visits. The study analyzed correlations between remedy temperament affinity and clinical improvement using repeated GAD-7 scores, of 97 participants, baseline anxiety was mild (7), moderate (69), severe (21). Post-treatment, 88 had minimal anxiety and 9 had mild residual anxiety. Most prescribed remedies: Lycopodium clavatum (24), Arsenicum album (21), Nux vomica (18), Sulphur (13), Silicea (11), Ignatia amara (8). Bilious/choleric temperament remedies dominated prescriptions. There is a relevant relationship between constitutional remedy temperament affinity and prescribing patterns in GAD within an individualized homoeopathic

framework. Temperament-oriented constitutional analysis could support psychobehavioral profiling in anxiety disorders. Further controlled research is required to validate this model.

Keywords: Generalized anxiety disorder, individualized medicine, constitutional prescribing, temperament theory, homoeopathy, GAD-7, psychobehavioral profiling

INTRODUCTION

Anxiety disorders are a global public health issue, with GAD being a chronic subtype causing significant psychological and functional impairment. GAD is characterized by excessive worry, autonomic arousal, restlessness, irritability, sleep disturbance, and poor concentration. Contributing factors include neurobiological vulnerability, personality traits, and environmental stressors. In India, anxiety disorders are a leading mental health concern. Current treatments (SSRIs, SNRIs, benzodiazepines, psychotherapy) have limitations such as delayed response, adverse effects, relapse risk, and variable patient response, highlighting the need for individualized models. Temperament theory—from Hippocratic and Galenic origins to modern psychobiological research—offers a framework for understanding personality and emotional characteristics. The four classical temperaments (choleric, melancholic, sanguine, phlegmatic) remain relevant for understanding behavioral patterns and constitutional medicine. In homoeopathic philosophy, temperament is integral to constitutional individuality and remedy selection. However, few clinical studies have systematically linked temperament, constitutional prescribing, and psychiatric outcomes using structured measures. This study addresses that gap in GAD management.

Conceptual and Theoretical Framework

This study is based on the intersection of:

- Contemporary anxiety psychopathology
- Classical temperament theory
- Constitutional homoeopathic prescribing

GAD presents with diverse behavioral and emotional profiles. Temperament theory helps organize these patterns, with homoeopathic constitutional medicine providing a parallel interpretive model. Remedies are matched to temperamental dispositions, and selection extends beyond diagnosis to constitutional patterns.

Research Objective: To explore temperament-based constitutional prescribing patterns and their clinical correlation in GAD patients under individualized homoeopathic treatment.

Research Gap: Current literature lacks prospective clinical studies on constitutional remedy temperament affinity in anxiety disorders using structured psychiatric outcomes. This study integrates temperament theory, constitutional analysis, and psychometric assessment.

METHODS

Study Design and Setting

A prospective, observational clinical correlation study was conducted from January 2021 to March 2023 at the Parul Institute of Homoeopathy, Parul University, Vadodara, Gujarat, India. The design focused on real-world constitutional prescribing, not protocolized interventions.

Ethical Considerations

- **Approval:** Institutional Ethical Committee, Parul University
- **Consent:** Informed consent obtained from all participants
- **Confidentiality:** Maintained per institutional and ethical standards

Participant Recruitment and Eligibility

Inclusion Criteria:

- Age 18–80 years
- DSM-5 diagnosis of GAD
- Anxiety symptoms present most days for ≥6 months
- At least three symptoms (excessive worry, restlessness, irritability, poor concentration, fatigue, sleep disturbance)
- GAD-7 score **≥10** or clinically significant
- Willingness for individualized homoeopathic management and follow-up

Exclusion Criteria:

- Panic disorder, social anxiety, trauma-related or phobic disorders
- Significant anxiety secondary to major somatic illness
- Concurrent conventional pharmacological treatment
- Unwillingness to participate or complete follow-up

Sample: 100 enrolled, 97 completed (3 discontinued before completion), Diagnostic Assessment Diagnosis was based on DSM-5 criteria and the GAD-7 scale (score 0–21): Homoeopathic Case Analysis and Prescription

Participants underwent detailed constitutional case-taking, including:

- Mental and emotional characteristics
- Behavioral tendencies
- Physical generals and modalities
- Constitutional attributes and symptom totality

Remedy selection was individualized; potencies included 200C, 1M, 10M. Each patient had 4–6 follow-ups for clinical and GAD-7 reassessment.

Temperament-Based Constitutional Correlation

Instead of independent temperament inventories, the study used:

- Individualized constitutional analysis
- Remedy selection based on classical homoeopathic principles
- Analysis of temperament affinity of prescribed remedies
- Correlation with clinical improvement

Remedy-Temperament Associations:

- Bilious/choleric: Nux vomica, Lycopodium clavatum, Sulphur
- Melancholic: Arsenicum album, Silicea, Ignatia amara, Kali phosphoricum
- Sanguine: Arnica montana
- Phlegmatic: No dominant cluster found

Statistical Analysis

Used descriptive and categorical methods:

- Frequencies, percentages
- Remedy distribution and gender-wise patterns
- Baseline and post-intervention severity
- Outcome analysis: Categorical comparison of GAD-7 severity pre- and post-treatment

Inferential statistics (e.g., chi-square, McNemar/Bowker tests) may be applied in future analyses.

RESULTS

Participant Flow and Completion

- **97 out of 100** completed clinical follow-up and were analyzed.

Most had moderate or severe anxiety at baseline. Most transitioned to minimal anxiety post-treatment. Male participants predominantly received Lycopodium clavatum and Nux vomica; Arsenicum album and Ignatia amara were more common in females.

DISCUSSION

The study integrates contemporary anxiety psychopathology, classical temperament theory, and constitutional homoeopathic prescribing. GAD presents with diverse psychobehavioral patterns, and temperament theory provides a framework for understanding this heterogeneity. The constitutional-temperament correlation model bridges individualized psychiatric understanding with constitutional therapeutics, offering a basis for future research in integrative mental health.

ABSTRACT

In order to comprehend students' academic paths, career decisions, and general social mobility, educational desire has become a key concept. It represents both a person's aspirations for their future level of education as well as the larger institutional, sociocultural, and economic factors that influence these aspirations. The current literature on educational aspiration is summarized in this review, with an emphasis on its dimensions and determinants. The review also covers important aspects of educational aspiration, such as the distinction between short-term and long-term objectives, academic vs occupational aspirations, and cultural differences. Aspirations are frequently mediated by structural inequities, but they also act as a strong motivator for academic perseverance, according to empirical research conducted in a variety of circumstances. There are also gaps in cross-cultural comparisons, longitudinal analysis, and the inclusion of marginalized groups in aspiration studies, despite a substantial corpus of research. The review ends by outlining the consequences for academics, educators, and politicians. It emphasizes the necessity of focused interventions, equitable support networks, and more research into the relationship between structural factors and individual agency. This research advances a more thorough knowledge of how aspirations impact educational results and outcomes by mapping the factors and dimensions of educational aspiration.The review ends by outlining the consequences for academics, educators, and politicians. It emphasizes the necessity of focused interventions, equitable support networks, and more research into the relationship between structural factors and individual agency. This study adds to a more thorough understanding of how aspirations affect educational results and more general social development by charting the factors and aspects of educational aspiration.

Keywords: Educational aspiration, socio-economic status, determinants, academic achievement, literature review.

INTRODUCTION

Aspiration is a seductive concept. In the context of education, it is difficult to argue against the notion that all young people should have high aspirations for their future, including academic and related life goals. The argument for setting and maintaining high objectives is that education can provide everyone the same chance to succeed if they so choose. (Bowers-Brown, T., Ingram, N., & Burke, C.2019). Aspiration has emerged as a key idea in both Australian and UK higher education (HE) policy, despite the fact that it is typically seen as a weakness among low-socioeconomic status (SES) groups rather than an available resource constrained by too interventionist social justice policies. In an effort to increase academic performance and student involvement, HE policy in both systems is granting universities greater power to conduct outreach programs in schools and the society at large.. (Sellar, S., & Gale, T.2009).Higher-achieving students are also more likely to come from low-income families and have lower academic achievement. These students also display a variety of academic and social risks. Children who had higher goals than they had expected, in instance, reported higher levels of behavioral and emotional difficulties, lower levels of school connection, and higher levels of performance and test anxiety. (Boxer, P., Goldstein, S. E., DeLorenzo, T., Savoy, S., & Mercado, I. 2011).The primary goal of education for students is academic accomplishment**.** The study of educational aspiration has also been approached using a variety of theoretical frameworks. The status attainment model emphasizes how important family background and socioeconomic level are(Sewell et al., 1969).Aspirations are broader, more ambitious goals that might motivate students to put in extra effort and stick with their studies, in contrast to educational expectations, which represent what students truly believe they will achieve(Khattab, 2015). (Sewell et al.1969) shown that parental socioeconomic position, personal aptitude, and the support of significant people all significantly influence educational aspirations, which in turn predict success in the future. Similar to this, Trusty (2000) pointed out that despite their academic struggles, teenagers usually have high aspirations, showing that goals may still be a source of drive. Scholars have, however, also drawn attention to the risks associated with having conflicting goals and expectations. (Boxer, Goldstein, DeLorenzo, Savoy, and Mercado 2011) found a robust relationship between socioeconomic disadvantage and academic risk factors, as well as differences between the two.This demonstrates that although goals can motivate accomplishment, they are frequently constrained by systemic obstacles. Additionally, Reynolds and Pemberton (2001) reported that American youth's desires to attend college increased throughout the 1980s and 1990s, reflecting broader societal shifts and the growing belief that a college education is essential for success. Together, these results suggest that educational aspiration is not only a psychological construct of the individual but also a socially entrenched phenomenon that is impacted by cultural, educational, and familial factors.

Present study aims to explore the key determinants that shape students' educational aspirations and to analyze the different dimensions through which these aspirations manifest. Numerous elements are among the variables, including peer pressure, parental support, family background, socioeconomic level, and the larger institutional and cultural context. By looking at these elements, the study aims to determine how ambition levels are influenced by a combination of psychological elements (such as motivation, self-concept, and resilience) and structural variables (such as educational possibilities and financial resources). At the same time, the study also focuses on the different dimensions of educational aspiration—ranging from immediate academic goals to long-term career ambitions—in order to understand how aspirations evolve and interact with students' lived experiences. By doing this, the study hopes to shed light on the chances and obstacles that might help or impede students from achieving their academic goals, in addition to emphasizing the role that desire plays in determining educational paths.

METHODOLOGY

This review adopts a systematic approach, drawing on peer-reviewed studies indexed in Scopus, Web of Science, and Google Scholar from 1990–2024. Keywords included "emotional maturity," "family status," "parenting style,"

"domestic influence," "adolescent development," and "emotional intelligence." Studies were selected based on empirical rigor, sample representativeness, and relevance to the review's objectives. The key findings are synthesized below.

Conceptual Understanding of Educational Aspiration

Educational aspiration, which reflects both personal objectives and the systemic opportunities that form them, has been a significant area of study in sociological and educational research. Aspirations are frequently defined as the degree of education that a person expects or intends to obtain, in contrast to expectations, which are more realistic evaluations of attainability given limitations such socioeconomic background, ability, and resources. (Khattab, 2015).The idea of educational aspiration has also been influenced by theories of social reproduction and potential. Sociologists contend that rather than existing freely, aspirations are influenced by a person's family background, societal standards, and structural injustices. For example, using longitudinal Young Lives data from India, (Serneels and Dercon 2014, 2021) demonstrate that mother aspirations have a significant impact on children's schooling trajectories, particularly in areas of poverty. Their results indicate that ambitions act as a moderator between socioeconomic adversity and educational performance.Additionally, aspirations are dynamic and vary over time in response to exposure, opportunities, and institutional support. In a natural experiment, (Beaman, Duflo, Pande, and Topalova 2012)found that the presence of female political leaders significantly raised the educational aspirations of teenage girls and their parents in rural West Bengal. This study emphasizes the significance of representation and role models in shaping aspirations by arguing that aspiration is partially socially constructed and responds to larger gender and cultural dynamics. In a more recent study, Flechtner (2024)examined longitudinal data from teenagers in Andhra Pradesh and Telangana to demonstrate how differences in ambitions appear early on. Children from disadvantaged backgrounds were more likely to have lower goals than their peers, particularly if they were less cognitively capable at age 12.

Together, these studies demonstrate that educational aspiration is a complex construct that is influenced by a variety of factors, including gender, family background, socioeconomic class, cognitive capacity, and institutional environments. Despite the fact that goals are commonly viewed as individual choices, research shows that structural factors and social contexts like families and communities have a big influence on them. This conceptual understanding is necessary to analyze how aspirations both reflect and reinforce educational disparity.

Determinants of Educational Aspiration

A complex interplay of institutional, cultural, familial, and personal influences shapes educational aspirations. Studies repeatedly show that ambitions are shaped within larger socioeconomic, cultural, and educational circumstances rather than existing in a vacuum. (Buchmann & Dalton, 2002; Khattab, 2015). The following sub-sections review the key determinants identified in the literature.

Socio-Economic Status (SES)

One of the most extensively researched indicators of educational aspiration is socioeconomic status. Children from more affluent families typically have easier access to opportunities, resources, and guidance that help them dream of pursuing higher education.(Sirin, 2005).Financial stability brought about by parental income and employment status enables families to make investments in high-quality education, tutoring, and extracurricular activities. On the other hand, low-SES students frequently experience financial limitations, restricted access to educational resources, and limited knowledge of higher education options, all of which can lessen their expectations. (Buchmann & Dalton, 2002).In addition, socioeconomic status (SES) has a significant impact on how teenagers formulate their goals. The primary goal of this work is to identify notable disparities in secondary school-aged adolescents' educational aspirations based on their socioeconomic condition and investigate the connection between the teenagers' socioeconomic situation and educational aspirations.(Salgotra, A. K., & Roma, K. (2018).Young people are not very interested in politics, business, or entrepreneurship, but they do want a job, particularly one in the government. Furthermore, their educational attainment and socioeconomic family backgrounds have no bearing on their goals. (Das, P. K., Panigrahi,J. K., Naik, I. C., & Das, B. 2019).Parents' socioeconomic standing has a significant impact on

how their children view their future and their educational goals. The majority of the guardians were from low socioeconomic backgrounds due to their low salary levels. This had an impact on the students' educational goals and school preferences. (Zang, P. L., Kwao, M. P., Anim, C. L., & Ahasu, E. K. 2024).

Parental Education and Involvement

One important factor influencing children's aspirations is parental education. In addition to offering academic help, parents with more education serve as role models for the importance of education. Participation in school activities, encouragement, and supervision of children's education all have a favorable correlation with desires for further education (Davis-Kean, 2005).On the other hand, children from low-education homes might not have access to role models who support higher learning objectives.Compared to parents in non-slum areas, parents in slums have lower expectations for their children's educational attainment; parents in slums have higher expectations for their children's educational success than for their own. (Oketch,M., Mutisya, M., & Sagwe, J. (2012).Compared to parents with lower levels of education, parents with greater levels of education typically set higher educational goals for their kids. parents own educational experiences and accomplishments may inspire them to set more ambitious objectives for their kids. (Sosu, E. M. 2014).

The purpose of Hill & Taylor's study was to look into the connection between the educational backgrounds of parents and the attitudes of students attending government and private universities. His findings showed that the pupils' attitudes varied significantly depending on the educational background of their parents.. (Hill & Taylor, 2004).Discussions between parents, teachers, and school administrators, as well as conversations with teenagers about their education and future aspirations, have the largest correlations with academic achievements among middle and high school students.

Family Structure and Environment

The structure of the family affects aspiration levels as well. Research indicates that when compared to pupils from broken home environments, those from intact homes with consistent emotional support tend to have higher goals. (Sun & Li, 2009).Home encouragement, emotional climate, and the quality of parent-child relationships all contribute to the development of a supportive atmosphere that fosters aspirations. Family expectations frequently greatly influence aspirations in collectivist countries, with kids adjusting their objectives to satisfy their parents' expectations. (Okagaki & Frensch, 1998).Another important factor is the home environment, particularly the level of parental participation. Drawing on data from rural China, (Wang et al. 2023) discovered that, even after controlling for peer and individual influences, adolescents who grew up in supportive family environments with high parental expectations, communication, and home learning resources were more likely to pursue ambitious educational goals. While stable single-parent families with supportive home environments can foster aspirations comparable to those in two-parent households, research from the Growing Up in Australia project indicates that family instability lowers parental involvement, which in turn lowers educational engagement and aspirations. (Hill and others, 2004)

Gender

Though trends differ among countries, gender still has a significant influence on educational goals. Girls are more likely than boys to want to pursue higher education in various situations, especially in industrialized countries (Schoon, 2006). However, gender norms frequently restrict girls' educational opportunities in patriarchal nations, steering them toward home responsibilities rather than postsecondary education or professional professions (Kirk, 2000). Boys are more likely to pursue STEM or things-oriented careers, while girls are more likely to pursue people-oriented careers, according to a large-scale analysis using 2018 PISA data. These gendered differences were especially noticeable in countries with higher levels of women's empowerment, suggesting that adolescents can pursue more intrinsically motivated pathways when they have access to greater societal resources. (Stoet & Geary, 2022).Compared to boys, girls in rural U.S. contexts reported much higher educational goals, higher family expectations for college, and greater involvement in college-preparatory programs, indicating that gender-based disparities persist even in settings with minimal resources.(Stoet & Geary, 2022) Gender significantly predicted these differences ($p < .01$). In addition, middle school girls in Finland were more likely than boys to choose academic paths,

with 53.1% of girls choosing academic paths versus 48.7% of boys, and boys choosing vocational aspirations more than twice as frequently (48.7% vs. 23.8%).(Finnish study, 2022).All of these results emphasize how gender influences educational goals through a variety of channels, including policy-mediated role modeling, family and community expectations, institutional opportunities, and society norms. Both at the domain-specific occupational level and at the more general educational planning level (academic vs. vocational courses), gender discrepancies are apparent. Interventions like female leadership have the ability to significantly close aspiration gaps.

Peer Influence and School Environment

In the formation of aspirations, schools and peers serve as potent socializing factors. While negative group pressure may deter students from pursuing academic goals, positive peer networks can motivate them to aim higher. The expectations, direction, and classroom environment of teachers have a big impact on how pupils view their academic ability. Schools that offer career guidance, mentoring, and exposure to higher education pathways help students achieve their educational goals. (Eccles & Roeser, 2011). Causal quasi-experimental research using UK longitudinal data demonstrates that classmates' socioeconomic status, aspirations, and achievement levels have quantifiable effects on people's intentions to continue their education and pursue academic paths. These effects are more pronounced for boys than for girls, and they can be somewhat offset by the information, counseling, and guidance programs offered by schools. (Dickerson, Maragkou, & McIntosh, 2018).Similar to this, research employing networked field tests and interventions shows that short informational and role-modeling treatments can change students' perceptions and, via peer contagion, increase aspirations in classrooms. (González Amador, Cowan, & Nillesen, 2022).

according to a study of Chinese adolescents living in rural areas. Peer aspirations and the quality of peer relationships were found to be directly related to students' own aspirations, although these effects were frequently mediated by individual factors like academic self-perception and goal valuation (Wang et al., 2023). Economic theory-informed empirical research also demonstrates that the makeup of peer income and ability can result in "reference-dependent" aspiration gaps: as low-income students' aspirations rise and high-income students' aspirations fall when the number of low-income peers in a cohort increases, with social cohesion moderating these effects (Fongoni, Norris, Romiti, & Shi, 2022).

Cultural and Community Context

Culture affects students' views on the importance of education, the kinds of jobs they find appealing, and the degree to which they think educational mobility is possible. Students in East Asian countries like China, Korea, and Japan consistently express a desire for higher education, which is a reflection of Confucian traditions that view hard work and academic success as moral obligations. (Buchmann & Park, 2009).Community-level research indicates that neighborhood norms and opportunities influence the ambitions of youth. Using longitudinal data from the United States, Harding (2011) discovered that, in large part because of inadequate role models and regional cultural scripts, teenagers in underprivileged urban neighborhoods frequently formed "survival-oriented" ambitions with low expectations for further schooling. According to Beaman et al. (2012), the presence of female political leaders in local village councils considerably increased the educational and career goals of both parents and girls, hence closing the gender gap. only are educational goals ingrained in people and families, but also in larger cultural norms and social settings. A compelling illustration of how community-level role models can alter cultural expectations and aspirations comes from a randomized policy "experiment" in rural India, where parents' aspirations for their daughters' education increased significantly when female leaders were assigned to village councils at random, and teenage girls themselves expressed higher educational and career ambitions (Beaman, Duflo, Pande, & Topalova, 2012). Finally, social influence can have a significant impact on communities. According to a European multi-site study, having several mentors even fewer than a whole village can have a good impact on teenagers' goals and achievements, highlighting the importance of communal ties beyond close friends and family (Singh et al., 2022).

Academic Achievement, Self-Concept, and Motivation

Students' goals are closely related to their academic achievement and self-perception. While recurrent academic setbacks may dampen aspirations, high performers typically have lofty educational goals. A major factor in encouraging students to continue higher education is academic self-efficacy, or the conviction that one can succeed (Bandura, 1997). Aspirations can also be shaped by internal motivation, resiliency, and future focus, especially in situations where there are no outside support networks.Students' academic performance, self-perception, and motivating styles are all strongly correlated with their educational goals. (Marsh and Martin 2011), for example, emphasized the reciprocal relationship between academic accomplishment and self-concept, demonstrating that improvements in self-concept predict later achievement and consequently influence students' educational paths. Similar to this, there is empirical evidence to support Eccles and Wigfield's (2002)expectancy value model, which holds that students' subjective task values and expectations of success have a significant impact on their educational choices and goals.Students who have confidence in their talents are more likely to create and stick to challenging academic objectives, according to Bandura (1997), Students with higher levels of intrinsic motivation and autonomous forms of control not only do better academically but also have higher goals for their future education, according to research based on self-determination theory (Deci & Ryan, 2000; Howard et al., 2021).

When combined, these results highlight how academic performance, motivation, and self-perception work in concert to influence students' ambitions, making them key factors in educational paths.

Meta analysis of the studies

In various contexts and approaches, the analyzed studies consistently emphasize that educational aspirations are influenced by a complex interaction of socio-economic status, parental education and engagement, family dynamics, peer relationships, cultural resources, and personal motivation. Quantitative studies and cross-sectional evaluations (e.g., Salgotra & Roma, 2018; Pandey et al., 2024; Wang et al., 2023) indicate that increased SES, parental educational levels, and encouraging peer settings boost aspirations, yet inequalities remain for underprivileged groups. Extensive international and longitudinal research (e.g., Stoet & Geary, 2022; Byun et al., 2012; Marsh & Martin, 2011) demonstrates lasting impacts of cultural capital, gender norms, and academic self-perception on influencing expectations. Evidence from experiments and policy studies (e.g., Beaman et al., 2012; González Amador et al., 2022) demonstrates that structural changes and peer effects can notably elevate aspirations. Theoretical and meta-analytic findings (e.g., Bandura, 1997; Deci & Ryan, 2000; Howard et al., 2021) elaborate on these trends, highlighting the importance of self-efficacy, autonomy, and motivation in converting goals into success. Together, the evidence highlights that aspirations are not just individual or fixed; rather, they are actively shaped by the interactions of family, friends, educational settings, and wider socio-cultural frameworks

Dimensions of Educational Aspiration

Dimensions show the many forms and orientations of educational ambition, while determinants describe the elements influencing it. According to Schoon and Parsons (2002) and Khattab (2015), scholars stress that ambitions are not uniform and instead take on distinct forms based on time, emphasis, and sociocultural environment. Subsections that follow go over the main dimensions found in the literature.

Short-Term vs. Long-Term Aspirations

One way to classify aspirations is by their temporal span. Short-term goals are imminent and frequently associated with impending milestones, such finishing high school or passing entrance exams. Conversely, long-term aspirations encompass more expansive educational and professional objectives, such going to college or following a certain vocation (Schoon, 2006).According to research, academic achievement and social competitiveness have a significant impact on short-term goals, whereas socioeconomic background, parental expectations, and cultural values determine long-term goals (Eccles & Wigfield, 2002).In their studies, college students frequently work for many objectives. While some goals are more specific to what students aim to achieve in the course—to learn as much as possible about the subject or to receive a good grade—other goals may be more broad and address why students are attending a particular class. Students who maintained consistent long-term goals throughout adolescence were more

likely to apply to and enroll in higher education institutions, according to Lakshmanan's (2004) longitudinal research employing NELS:88 data. On the other hand, those with erratic or poor short-term aspirations were less likely to be in line with postsecondary opportunities. Using a sizable Finnish sample,Dobewall et al. (2019)discovered that short-term variables like teenage health had a significant impact on students' choice between academic and vocational paths. Longer-term academic ambitions were associated with better health, whereas students with worse health issues were more likely to pursue short-term, vocational goals.

Academic vs. Occupational Aspirations

The connection between academic aspirations—the desire to pursue higher levels of formal education—and occupational aspirations—career-related objectives—is another crucial factor. Despite their frequent connections, the two are not always in agreement. For instance, one student may pursue further education without a defined career route, while another may want to become a professional artist but not necessarily seek advanced degrees (Gottfredson, 1981). Research indicates that disparities between academic and professional goals are frequent, especially when educational systems fail to sufficiently connect learning to employment prospects. (Khattab, 2015).Valls et al. (2022)identified eleven unique patterns of educational and vocational goals in a three-year longitudinal study of Vienna students moving from lower to upper secondary school. According to the study, the majority of students kept their goals same throughout adolescence, but differences that were greatly influenced by factors including parental education, migration history, and school achievement show how academic and professional objectives differed and interacted. A longitudinal research in the United States by Beal and Crockett (2010) looked at the relationship between the academic and career goals of teenagers and their subsequent educational success. Adolescents followed into young adulthood comprised the study's nationally representative sample. Students' self-reported goals, involvement in extracurricular activities, and school engagement were the main topics of questionnaires used to gather data.The findings revealed that adolescents who held high academic and occupational aspirations were more likely to participate in structured school and career-related activities, such as advanced coursework and extracurricular programs.

Individual vs. Collective Aspirations

Okagaki and Frensch (1998)investigated how cultural values affect ethnic minority families' goals for education and careers in the US. Based on surveys and interviews with immigrant parents and teenagers, their study examined the framing of ambitions on both an individual and group level. The results demonstrated how collective values, such as meeting expectations, supporting the home financially, and upholding cultural customs, significantly influenced ambitions in many immigrant households. Adolescents also indicated personal goals at the same time, such as pursuing occupations that fit their interests, growing personally, and becoming more independent. Family expectations and a desire to preserve honor as a group, rather than merely individual achievement, have a significant impact on students' educational goals in many collectivist environments.In rural central China, for example, Xiaodi Chen et al. (2023) carried out a thorough investigation with 606 adolescents (average age ~14.85 years, 50% boys). They discovered that parents' goals had a greater impact on kids' own learning goals than did peers', highlighting the significance of family expectations in these contexts. Furthermore, via influencing personal characteristics including academic self-perception, self-regulation, and goal valuation all of which were very significant predictors of students' ambitions attachments to parents and close friends indirectly supported educational aspirations. Pindar and Singh (2021), in a comparative research in Haryana, India, examined the disparities between rural and urban secondary school students' scholastic goals and family support. Their results showed that, in comparison to their rural counterparts, urban kids had far higher educational goals and more family support. With urban kids enjoying more supportive surroundings and rural pupils still facing limitations due to a lack of academic assistance and role models, this study eloquently demonstrates how geographic context impacts aspirational aspects.In a comparative research,Li and Hou (2022)looked at the educational aspirations of junior high school pupils in China's migrant, urban, and rural communities. They found that urban students had far higher desires to pursue higher education than their rural and migrant counterparts, based on data from Southwest University in Chongqing. Differences in family background, cognitive ability, and school environment were cited as the reasons for this discrepancy. Family background was found to have a greater impact than individual cognitive factors, and institutional segregation

associated with the hukou (household registration) system was found to be the most significant structural barrier affecting rural students. Even after taking individual aptitude into consideration, this study demonstrates how socio structural and geographic constraints combine to restrict the educational goals of rural students. According to the results, young people who believe their parents have higher expectations for their education are far more likely to want to attend college. On the other hand, people were less inclined to seek higher education if they saw more employment chances in their rural towns. In addition, the study discovered that men tended to have a greater rural identity associated with local employment, whereas women reported higher enrollment rates and goals.

Realistic vs. Idealistic Aspirations

Researchers discovered a pervasive aspiration–expectation gap in a groundbreaking study of middle school pupils in rural central China. The children frequently wanted to go to college but had more conservative expectations because of perceived limitations. Notably, teenagers left behind by migratory parents indicated very high ambitions but much lower expectations. While limitations like parental absence and subpar academic achievement stifled reasonable expectations, parents' educational goals particularly mothers had a favourable impact on adolescents' idealistic hopes. Higher psychosocial risk, including depression, and poorer academic self-regulation were linked to the ensuing mismatch (Ye et al., 2021).In order to investigate the difference between educational ambition (idealistic hopes) and educational expectation (realistic projections),Yan (2022)examined national statistics. Practical variables including family wealth, the number of siblings, and the child's academic achievement greatly influenced realistic expectations, even if parental goals were consistently high and generally unaffected by socioeconomic restraints. The study highlights how systemic socioeconomic hurdles may prevent practical educational planning, even if many families foster high goals**.** Khattab et al. (2022) conducted a research on seventh and eighth graders in Qatar that shed light on the difference between expectations based on practical realities and idealistic educational ambitions. Parental expectations, demographics, and personal views all had an impact on the mismatch between students' ambitions and expectations, which were often greater.

Meta Analysis of the studies

In various contexts, research consistently emphasizes that adolescent educational and occupational aspirations are both fluid and hierarchical. Longitudinal research (Schoon, 2006; Beal & Crockett, 2010; Lakshmanan, 2004; Valls et al., 2022) indicates that consistent long-term goals forecast greater educational achievement and career fit, whereas inconsistent or misaligned objectives (Khattab, 2015; Ye et al., 2021) frequently hinder success in postsecondary education. Socioeconomic status, expectations from parents, and cultural context stand out as the strongest factors (Chen et al., 2023; Agger et al., 2018; Yan, 2022), influencing not only the level of aspirations but also the practicality of expectations. Comparative research (Pindar & Singh, 2021; Li & Hou, 2022) shows ongoing rural–urban disparities, where urban youth express greater ambitions due to enhanced parental support and structural resources, while rural and migrant students encounter systemic obstacles. Health and academic achievement also act as significant mediators (Dobewall et al., 2019; Harackiewicz et al., 2000). Collectively, the evidence indicates that although young people frequently set high aspirations, the realization of these goals relies on family backing, available opportunities, well-being, and a steady focus on long-term objectives

Limitations of the Study

The current review has limitations even if it offers insightful information about the factors and aspects of students' educational goals. First, the study relies heavily on secondary data from previous studies, which may limit the breadth of contextual knowledge and make it impossible to see students' actual experiences firsthand. Second, research carried out in Western, developed environments, such the US, UK, and Australia, make up the majority of the evaluated literature. Because of this, the results might not be entirely applicable to educational environments that are developing or culturally diverse. Third, because desire is dynamic and multifaceted, it is challenging to fully capture all contributing aspects, especially those that are subtle, context-specific, or changing quickly in response to social and technological advancements. Lastly, discrepancies in methodological techniques and definitions of ambition between research may result in some conceptual contradictions because this study synthesizes data from a variety of theoretical frameworks.

The study offers a crucial basis for comprehending educational goals in spite of these drawbacks and identifies areas where more complex, context-sensitive insights might be obtained from future research.

Implications and Future Research Directions

For educators, legislators, and academics, the study's conclusions have a number of significant ramifications. Comprehending the factors that influence students' academic goals emphasizes the necessity of loving family settings, fair resource distribution, and inclusive institutional policies. In order to encourage students from underprivileged socioeconomic backgrounds to have realistic yet ambitious goals, schools and colleges should create focused interventions including outreach programs, career counseling, and mentorship programs. In addition to emphasizing academic success, policymakers must also build systems that support and uphold students' long-term goals in order to lessen educational disparity. Future studies should expand on the findings of this study by using a wider range of methodological techniques and being more context-sensitive. To track how ambitions evolve and alter over time in response to life events, transitions, and changing socioeconomic circumstances, longitudinal studies are required. Comparative research across national and cultural contexts can shed light on how educational goals are influenced differently in various environments. Furthermore, a more comprehensive knowledge of students' goals, drives, and difficulties would be possible through the integration of mixed methodologies, which combine quantitative measurements with qualitative narratives. Lastly, future research should look at how new elements like social media, digital technology, and global mobility affect how young people see and pursue their educational careers.

CONCLUSION

Long acknowledged as a key idea in educational research, educational desire acts as a link between personal ambition and systemic opportunity. A complicated interaction between family history, socioeconomic circumstances, gender, school environment, peer networks, and cultural expectations shapes ambitions, as the reviewed research shows. While more recent studies (Khattab, 2015; Sharma & Sharma, 2015) emphasize the significance of contextual disparities like ethnicity, rural–urban divides, and access to educational resources, classic studies (Sewell, Haller & Portes, 1969; Marjoribanks, 2003) emphasized the impact of family and school. This review offers some important insights. First, while ambitions might inspire success, they can also constrain aspirations, resulting in cycles of adversity. ambitions are both predictors and consequences of educational attainment. Second, goals are not static but rather dynamic, changing as people go through different phases of life and in reaction to shifting social, cultural, and economic circumstances. Third, even if the majority of students have lofty ideals, it takes supporting regulations, sufficient funding, and organized instruction to turn them into achievable objectives. The analysis also identifies important gaps in the body of current research. Relatively few studies come from developing nations, where socioeconomic gaps are glaring, and the majority of research is still focused on Western contexts. Furthermore, there are not many longitudinal or intersectional viewpoints, which leaves open concerns of how ambitions change over time and interact with elements like caste, ethnicity, or 21st-century internet access. The requirement for context-sensitive research and treatments is critical going ahead. Aspirations can grow in circumstances created by policies that assist families, lessen socioeconomic disparities, and ensure equal access to high-quality education. Integrating mentorship, career counseling, and culturally sensitive education is equally crucial in ensuring that students' goals are both challenging and reachable. In summary, educational desire is still a strong indicator of academic and professional success, but its fulfillment relies on the cooperation of structural assistance and personal drive. By tackling socio-economic and cultural obstacles and bolstering educational and community support networks, we may establish an environment that fosters the development and realization of ambitions.

ACKNOWLEDGEMENT

The authors would like to grateful to Swami Vivekanand Subharti University, Meerut, India for its academic support and resources, which greatly facilitated the completion of this task.

Conflict of Interest

The authors of this article state that they have no known financial or personal ties that may have looked to have influenced the work described. There has been no outside funding or support for this review; it is entirely based on scholarly curiosity and the body of existing material.

Funding

There was no outside funding support or financial aid available for the current review research.

Table : 1 Studies of different Determinants of Educational Aspiration

Author(s) (Year)	Title (source)	Methodology and sample	Key finding (one line)
Salgotra, A. K., & Roma, K. (2018).	Educational aspiration and socio-economic status among secondary school students.	Quantitative, survey of 351 students in Jammu district.	Students with **higher socio-economic status** reported significantly **higher educational aspirations** compared to those from lower SES backgrounds.
Das, P. K., Panigrahi, J. K., Naik, I. C., & Das, B. (2019)	Examination of socio-economic and socio-cultural factors influencing aspiration levels of youth with respect to their education levels	Quantitative, experimental examination of 384 college-going students	There is no significant difference between male and female in their level of aspiration
Zang, P. L., Kwao, M. P., Anim, C. L., & Ahasu, E. K. (2024).	Socio-economic characteristics of parents on learners' educational aspiration: Exploring mechanisms of impact	descriptive survey design, employing a sample of learners (230) of the Greater Accra region of Ghana.	parental background and economic standing collectively impact youth's vision for their academic future.
Oketch, M., Mutisya, M., & Sagwe, J. (2012).	Parental aspirations for their children's educational attainment and the realisation of universal primary education in Kenya	The study used cross-sectional household data for a sample of 4065 parents, collected in 2007 by the African Population	Parents in both slum and non-slum areas of Nairobi held high educational aspirations for their children
Sosu, E. M. (2014).	Predicting maternal aspirations for their children's education: The role of parental and child characteristics.	Quantitative, analysis using secondary data (N=1999)	Results showing a positive relationship between maternal age and educational aspirations of the children
Pandey, P. K., Pandey, P. K., Mahajan, S., Srivastava, N., & Asif Shah, M. (2024).	Examining the impact of parental education and socio-demographic factors on career aspirations in adolescent students in Delhi NCR, India: A cross-sectional study.	Cross-sectional survey research,**440 adolescent students** from various schools in Delhi NCR region.	The results showed significant differences in the attitudes of students at private and government universities, and a significant effect of parental education, but no significant impact of gender. Delhi NCR region of India.
Hill, N. et al. (2004).	Parent academic involvement as related to school behavior, achievement, and aspirations: Demographic variations across adolescence.	Survey method is used, 463 adolescents, followed from 7th through 11th grades in the **United States**.	Parental academic involvement positively predicts adolescents' school behavior, academic achievement, and educational aspirations across diverse demographic groups.
King, V., Pragg, B., & Lindstrom, R. (2020)	Family structure, step-parents' aspirations, and college attendance. Journal of Family Studies.	Secondary analysis of Add Health longitudinal data of US. Adolescents	Stepfathers' relationships with stepchildren had no direct effect on educational attainment, but both stepfathers' and mothers' **expectations** significantly shaped college intentions and attendance.

Fan & Williams (2010)	The differential effects of parental involvement on high school completion and postsecondary attendance.	Quantitative, survey-based analysis. sample of thousands of high school students in U.S.	Parental involvement (school activities, home-based support) and **parental aspirations** were strong predictors of high school completion and college enrollment.
Wang et al. (2023)	The influence of individual, peer, and family factors on educational aspirations: Evidence from rural China.	using survey questionnaires of 1,313 rural Chinese adolescents	Individual motivation, peer influence, and parental support all significantly predicted students' educational aspirations
Beaman, Duflo, Pande & Topalova (2012),*Science*	Female leadership raises aspirations and educational attainment for girls: a policy experiment in India.	Descriptive survey of 8,453 adolescents & parents.	Female leadership raised girls' aspirations, reduced gender gap in education and chores, and eliminated schooling gap.
Stoet & Geary (2022)	Sex differences in adolescents' occupational aspirations: Variations across time and place.	Secondary analysis of 473,260 adolescent.	Gender gaps were **larger in gender-equal & wealthy countries.** Parental modeling also influential.
Dickerson, Maragkou & McIntosh (2018)	The causal effect of secondary school peers on educational aspirations	Qualitative research, 7,938 pupils were sample in England	School peers causally influence aspirations to stay in education and choose academic post-compulsory paths, identified using peers-of-peers strategy.
González Amador, Cowan & Nillesen (2022)	Peer networks and malleability of educational aspirations	Experimental research design 1500 students of 45 high schools in **Mexico were sample**	The video intervention significantly increased students' educational aspirations and demonstrated peer network interdependencies.
Roeser, R. W., & Eccles, J. S. (2014).	Schooling and the mental health of children and adolescents in the United States.	a conceptual and review chapter on **multiple U.S. datasets and studies**.	School environments strongly shape both **academic achievement and mental health outcomes.**
Buchmann, C., & Park, H. (2009).	Stratification and the formation of expectations in highly differentiated educational systems.	Comparative study, Data from **OECD and cross-national surveys of**Germany, Japan, Korea.	In systems with **early and rigid tracking**, students from lower socioeconomic backgrounds formed **lower educational expectations**early.
Byun, S. Y., Schofer, E., &Kim, K.-K. (2012).	Revisiting the role of cultural capital in East Asian educational systems: The case of South Korea.	Longitudinal Survey method, 5,000 middle and high school students in South Korea were sample.	**Cultural capital** (remained a strong predictor of aspirations and attainment in South Korea, despite high standardization of schools.
Harding, D. J. (2011).	Rethinking the cultural context of schooling decisions in disadvantaged neighborhoods: From deviant subculture to cultural heterogeneity	qualitative research method, Adolescents and families in low-income urban communities in the U.S. were sample.	Educational aspirations are shaped as much by **neighborhood cultural context**as by family or school.
Deci, E. L., & Ryan, R. M. (2000).	The "what" and "why" of goal pursuits: Human needs and the self-determination of behavior. Psychological Inquiry,	Theoretical review paper from the **US, Canada, and Europe.**	Satisfaction of three needs (autonomy, competence, relatedness) promotes **internalized motivation, well-being, and persistence.**

Eccles, J. S., & Wigfield, A. (2002).	Motivational beliefs, values, and goals. Annual Review of Psychology	**Comprehensive reviewongitudinal studies with school-aged children and adolescents**, of United States	Students' achievement-related choices and performance are strongly predicted by their **expectancies for success** and the **value they assign to tasks** , shaped by social, cultural, and gender influences.
Marsh, H. W., & Martin, A. J. (2011)	Academic self-concept and academic achievement.	Longitudinal and cross-lagged panel analyses of **school and university students** (Australia	Students with higher self-concept show greater persistence, motivation, and long-term achievement.

Table : 2, Studies related to different Dimensions of Educational Aspiration

Author(s) (Year)	Title (source)	Methodology and sample	Key finding (one line)
Schoon (2006)	Teenage aspirations for future careers and occupational outcomes.	Longitudinal and comparative analysis,	Short-term aspirations are linked to school performance, while long-term aspirations are strongly shaped by socio-economic and cultural contexts
Harackiewicz et al. (2000)	Short-term and long-term consequences of achievement goals: predicting interest and performance over time.	Longitudinal study, 250 students in psychology courses of U.S. college	Mastery goals predicted sustained interest and learning, while performance goals predicted short-term grades but not long-term engagement.
Lakshmanan (2004)	A longitudinal study of adolescent educational aspirations and their relationship to college choice using hierarchical linear modeling and group-based mixture modelling	Longitudinal quantitative study, 88 U.S. adolescents was sample.	Stable long-term aspirations strongly predicted college application and enrollment, whereas fluctuating short-term goals reduced postsecondary alignment.
Dobewall et al. (2019)	Health and educational aspirations in adolescence: A longitudinal study in Finland.	Longitudinal survey-based study, n ≈ several thousand, national cohort data	Good adolescent health supported long-term academic aspirations, while poor health conditions led to vocational, short-term oriented pathways.
Khattab (2015)	Explaining the educational aspirations–expectations mismatch among middle school students: The role of parental expectations, attitudinal and demographic factors.	large-scale survey method, UK adolescents across ethnic and socioeconomic groups was sample.	Misalignment between educational and occupational aspirations is common, especially in systems with weak school-to-work transitions.
Valls et al. (2022)	Educational and occupational aspirations: A longitudinal study of Vienna youth.	**longitudinal study, 100**Students in Vienna was sample.	Aspiration development showed 11 stable patterns, diverging mainly due to migration background, parental education, and school performance.
Beal & Crockett (2010)	Adolescents' occupational and educational aspirations and expectations: Links to high school activities and adult educational attainment.	Longitudinal survey-based study, U.S. nationally representative sample of adolescents	High academic and occupational aspirations predicted greater engagement in advanced coursework, extracurricular participation, and higher adult educational attainment.

Chen, Allen, & Hesketh (2023)	The influence of individual, peer, and family factors on the educational aspirations of adolescents in rural China. *Social Psychology of Education*.	Quantitative survey, 606 adolescents wsa sample.	**Parental aspirations** had the strongest influence on students' educational goals, while peer influence was weaker; family attachment and friendships indirectly shaped aspirations .
Pindar & Singh (2021)	A comparative study on educational aspiration and parental encouragement among rural and urban high school children.	Comparative survey, N = 240 (120 urban Hisar, 120 rural Fatehabad, Haryana, India)	urban students showed significantly higher educational aspirations and greater parental encouragement than rural peers
Li & Hou (2022)	Differences in educational expectations between urban and rural junior high school students: Individual, family, and socio-structural influences.	Comparative study using survey data from Southwest University, Chongqing, China;	urban junior high students reported higher educational expectations than rural and migrant peers, with disparities driven by family background, school environment, and hukou-related structural barriers
Agger, Meece & Byun (2018)	The influences of family and place on rural adolescents' educational aspirations and post-secondary enrollment.	Nationwide U.S. survey, N = 3,456 rural adolescents	higher parental expectations predicted greater aspirations and college enrollment, while local job opportunities lowered aspirations
Ye et al. (2021)	On class differences in educational aspirations and educational expectations: A social analysis based on national data.	Survey of rural middle school students in central China	As a result, children left behind showed high aspirations but low expectations.

ABSTRACT

The COVID-19 epidemic has sped up the digitization of education, transforming conventional learning settings into online, digital, and hybrid formats. This paradigm change has given students access to digital platforms, virtual classrooms, and cutting-edge educational technology that have never before offered them flexibility, accessibility, and interactive learning experiences**.** New difficulties have been brought about by the shift, nevertheless, especially in regards to students' increased academic stress. Stress levels have been considerably impacted by elements including excessive screen time, a lack of in-person peer connection, technical hurdles, ongoing evaluations, and a blurring of the lines between personal and academic life**.** This review study critically investigates the intricate connection between academic stress and learning outcomes in the digital age. It examines the main sources of stress, mediating factors such resilience, emotional intelligence, and self-regulation**,** and coping mechanisms used by students in online learning settings**.** The study also emphasizes how stress experiences differ among socioeconomic backgrounds, fields, and demographics**.** Untreated stress can have a detrimental effect on motivation, cognitive function, and overall academic accomplishment, according to the findings, even while digital education can increase engagement and improve specific learning outcomes**.** The review's conclusions highlight the importance of learner-centered approaches, mental health support, balanced digital pedagogy, and sustainable educational policies for ensuring that the digital transformation of education fosters both academic success and student well-being.

Keywords- academic stress, learning outcomes, digital age, emotional intelligence, self-regulation**,** time management, psychological problems, academic performance

INTRODUCTION

Global education has undergone significant change as a result of the digital age, making online, hybrid, and blended learning essential elements of contemporary academic life. This change was expedited by the COVID-19 epidemic, which forced a dramatic change in the dynamics of teaching and learning by requiring a quick transition from traditional classroom-based instruction to technology-mediated learning platforms (Dhawan, 2020; Adedoyin et al. 2020). This shift has created a new set of difficulties that have a significant impact on students' academic and mental health, even while it has also increased chances for flexible learning, easy access to educational materials, and collaborative involvement through digital platforms.One of the foremost concerns emerging from digital learning environments is **academic stress,** a phenomenon traditionally associated with examinations, workload, and peer competition (Pascoe et al. 2020). In the digital context, academic stress now manifests in novel forms, such as excessive screen time leading to fatigue, information overload due to constant exposure to digital content, and technical barriers like unstable internet connectivity or lack of adequate devices (Sahu, 2020; Maqsood et al., 2021). These challenges are compounded by the lack of face-to-face social interaction, which can lead to feelings of isolation, reduced peer support, and diminished motivation (Chaturvedi et al., 2021).

Additionally, the online modality brings with it additional academic stresses such as anxiety related to online assessments, the pressure of ongoing evaluation, and digital distractions from multitasking and social media (Mahapatra et al., 2021). Since students work in settings where the lines between their personal and academic lives are blurred, these stresses are frequently ubiquitous and hard to control, in contrast to conventional ones. Digital learning resources are available around-the-clock, which is advantageous, but it may also encourage an over-engagement culture that leads to fatigue and decreased academic productivity (Hossain et al., 2022).It is crucial to comprehend how these stresses interact with learning objectives. It has been demonstrated that academic stress exacerbates mental health conditions including anxiety and depression and has a detrimental impact on focus, cognitive function, and overall success (Wang et al., 2022; Zhao, 2022). On the other hand, when utilized properly, some digital platforms may foster self-regulated learning, resilience, and collaborative involvement, all of which reduce stress and improve performance (Aslan et al., 2022; Mishra et al., 2023).Investigating the dual character of digital education—both a source of academic stress as well as a facilitator of academic growth—is crucial. By looking at major stressors, mediating characteristics including emotional intelligence and self-regulation, and coping strategies used by students, this review study aims to examine the link between academic stress and learning outcomes in the digital age. In order to help educators, institutions, and policymakers create supportive, balanced, and sustainable digital education environments that foster both academic performance and student well-being.

METHODOLOGY

This review paper adopts a systematic methodology to analyze the existing literature on academic stress in digital learning environments. The process involved identifying, selecting, and synthesizing relevant studies to ensure a comprehensive understanding of the topic. To begin with, major academic databases such as Scopus, Web of Science, ERIC, Springer Link, Taylor & Francis, and Google Scholar were searched to collect peer-reviewed articles, conference papers, and reports. The review applied Studies published between 2020 and 2025, peer-reviewed articles, and papers focusing on students' academic stress, coping mechanisms, and digital learning environments were included. Through this systematic approach, the review ensures credibility, thematic clarity, and a holistic understanding of the multiple dimensions of academic stress in digital learning contexts.

RESULT AND DISCUSSION

Academic Stress in the Digital World

Academic stress in the digital world has become a growing concern for students as they cope with the challenges of online and technology-driven learning. The constant pressure to meet deadlines, adapt to digital platforms, and perform well in virtual assessments often results in heightened anxiety and burnout (Pascoe et al., 2020). Increased screen time, limited face-to-face interaction, and reduced peer support further intensify feelings of isolation and stress (Son et al., 2020). Moreover, high parental expectations, competitive academic culture, and the overwhelming flow of online information contribute to the psychological burden on learners (Hasan et al., 2020). While digital education provides flexibility and access to vast resources, the imbalance between academic demands and student well-being underscores the need for effective coping strategies, self-regulated learning, and institutional support to mitigate stress and ensure holistic development (Dhawan, 2020).

Sources of Academic Stress-

The various elements, circumstances, or events in a student's academic life that produce pressure, tension, or worry regarding learning, studying, and performance are known as sources of academic stress (Pascoe et al., 2020). Sources of academic stress are shown in diagram -1 which are:

Technological Barriers

In digital learning contexts, technological obstacles are one of the biggest causes of academic stress. Students usually experience unreliable platforms, restricted bandwidth, and bad internet access, which interferes with the continuity of online courses and tests (Dhawan, 2020). Additionally, the absence of computers, tablets, or current software, among other device constraints, exacerbates digital inequality, especially for pupils from underprivileged or rural backgrounds (Adedoyin et al., Increased cognitive load and decreased learning efficiency result from irritation heightened by unfamiliarity with digital technologies, online learning management systems, and virtual communication platforms (Maqsood et al., 2021). These technology interruptions cause emotions of powerlessness, anxiety, and disengagement in addition to impeding academic achievement.

Workload and Time Management

In contrast to traditional classroom settings, the digital method of education requires greater degrees of autonomy and self-regulation. It can become burdensome for students to be expected to manage several assignments, take part in online conversations, and fulfill deadlines without explicit supervision (Agung et al., 2020). Although online learning offers flexibility, it also blurs the lines between personal and academic life, making it challenging for students to maintain balance (Bao, 2020). When combined with constant messages and digital multitasking, poor time management skills frequently lead to procrastination, last-minute stress, and subpar performance (Mishra et al., 2023).

Screen Fatigue

Another major stressor in the digital academic environment is prolonged use of digital screens. Long periods of time spent participating in conversations, doing projects, and watching online lectures might cause headaches, musculoskeletal pain, eye strain, and short attention spans (Wang et al., 2021). The lack of outdoor activities and physical breaks during digital learning, particularly during COVID-19 lockdowns, exacerbates this issue, which is known as screen weariness (Sultana et al., 2021). Learning results are directly impacted by the cognitive stress brought on by multitasking, simultaneous video conferencing, and constant alerts, which impair focus and memory.

Isolation and Lack of Peer Support

Students' emotional and intellectual well-being is greatly impacted when they are unable to engage with peers and teachers in person. Digital settings frequently lack the informal chances for peer support, encouragement, and cooperation that traditional classrooms offer(Adedoyin et al., 2020). Feelings of loneliness, alienation, and a lack of

belonging in the academic community might result from isolation in digital learning (Chaturvedi et al., 2021). Lack of in-person support and social connections deters many students from being motivated, which raises academic stress and lowers resilience when faced with difficult assignments.

Assessment Pressure

Another significant cause of stress is taking tests and evaluations online. Particularly in the lack of uniform monitoring, students frequently voice worries about the integrity, fairness, and dependability of digital assessments (Besser et al., 2020). Anxiety during high-stakes testing is increased by technical issues such system crashes, erratic internet, or late submissions (Wang et al., 2022). Stress levels are further increased by peers' concern of academic dishonesty and the opaqueness of grading (Mahapatra et al., 2021). Academic insecurity has increased in the digital age due to the need to adjust to new forms, including timed online quizzes, open-book digital examinations, and continuous evaluation.

In this table-1 there are the sources of academic stress, issues and their impact on students. The examination of digital academic stresses reveals that although each element has an impact on students' wellbeing on their own, they are also intricately linked. When students are unable to connect consistently, technological hurdles might exacerbate workload, assessment pressure, and even feelings of loneliness (Dhawan, 2020; Maqsood et al., 2021). Similar to this, ineffective time management in digital settings increases screen exposure and workload stress, which results in weariness and cognitive deterioration (Agung et al., 2020; Wang et al., 2021). Long-term seclusion, compounded by a lack of support from peers and teachers, lowers motivation, which increases kids' susceptibility to procrastination and test anxiety (Chaturvedi et al., 2021; Mahapatra et al., 2021).

Assessment pressure is the most significant stressor of all as it directly affects academic confidence and results by combining workload demands, technological uncertainty, and equality concerns (Besser et al., 2020; Wang et al., 2022). Therefore, the cumulative and interrelated consequences of technological, cognitive, and social constraints in online learning settings are the cause of digital academic stress rather than a single element.

Psychological Impacts of Digital Academic Stress

In the digital age, academic stress has a substantial impact on students' psychological and emotional health in addition to their academic success. A number of psychological effects, including anxiety, burnout, depression, and decreased motivation, are frequently the result of the interaction between technology hurdles, workload, isolation, and evaluation anxiety. Diagram-2 shows the **Psychological Impacts of Digital Academic Stress**

Anxiety and Uncertainty

Students' anxiety levels are raised by frequent technological difficulties, erratic internet connections, and doubts regarding online test protocols(Sahu, 2020). This ongoing state of anxiety is exacerbated by the unpredictability of digital learning platforms and the anxiety of missing deadlines or losing assessment chances because of technological difficulties (Besser et al., 2020). According to research, anxiety brought on by digital learning is strongly associated with worse learning outcomes and less academic engagement (Maqsood et al., 2021).

Burnout and Fatigue

Academic burnout is the term used to describe the mental and physical tiredness that is frequently caused by prolonged academic demands and constant exposure to digital technologies (Wang et al., 2021). The lines between study and rest are frequently blurred in digital learning environments, in contrast to conventional learning environments where regular schedules and physical breaks offer respite. Over-engagement is encouraged by the continual availability of learning materials, which leads to exhaustion, demotivation, and disengagement from educational activities (Sultana et al., 2021).

Depression and Social Isolation

Feelings of isolation and alienation are greatly increased when in-person peer support and classroom contact are absent. Long-term seclusion has been associated with depressive symptoms, especially in students who are highly motivated to study in groups and through collaborative learning (Adedoyin et al., 2020; Chaturvedi et al., 2021). In digital contexts, a lack of social connections not only impairs academic perseverance but also emotional resilience.

Reduced Motivation and Self-Efficacy

Digital academic pressures also affect self-efficacy and motivation, two important factors that determine learning achievement. Students' confidence in their capacity to meet academic objectives is frequently undermined by digital distractions, multitasking demands, and anxiety related to online assessments(Mahapatra et al., 2021). Learning outcomes are further diminished by avoidance behaviors, procrastination, and lower involvement in academic activities brought on by this lack of self-belief (Mishra et al., 2023).

Cognitive Overload

Cognitive overload, which affects memory, focus, and critical thinking, is brought on by the sheer amount of digital information, continuous notifications, and multitasking demands **(Wang et al., 2022).** Stressed-out students frequently have trouble processing information efficiently, which impairs their performance on tests and retention of long-term learning. These are the psychological impacts on digital academic stress. Which are interpret in the given table- 2

Instead than being separate, the psychological and emotional effects of digital academic stress are linked and reinforce one another. As students find it difficult to absorb information under pressure, anxiety and confusion brought on by erratic technology and ambiguous procedures (Sahu, 2020; Maqsood et al., 2021) frequently turn into cognitive overload (Wang et al., 2022). According to Wang et al. (2021), prolonged exposure to stresses like these might result in burnout and tiredness, which lowers physical energy and academic interest. Simultaneously, the lack of peer relationships leads to social isolation and despair, which further reduces resilience and the capacity to handle academic expectations (Chaturvedi et al., 2021).This loop erodes students' self-efficacy and motivation, which in turn erodes their confidence in their ability to achieve (Mahapatra et al., 2021; Mishra et al., 2023). Burnout and decreased motivation are the most important long-term effects among these as they not only affect academic performance but also have a detrimental impact on students' attitudes toward learning and wellbeing for the rest of their lives. Interventions must thus target both the individual stresses and the cumulative and cyclical consequences on kids' academic performance and mental health.

Behavioural Impact

Students are suffering from severe psychological and behavioural effects as a result of the increased academic stress brought on by the growth of digital learning environments. Digital stressors, in contrast to conventional types of academic stress, frequently combine academic, social, and technical pressures, which increases their negative effects on learning outcomes and mental health. Behavioural Impact are shown in the diagram-3

Anxiety and Emotional Distress

According to studies, students' anxiety levels are considerably increased by digital stressors such erratic internet access, ambiguity in online tests, and an ongoing workload (Hasan et al., 2020; Sahu, 2020). Chronic anxiety impairs academic performance, focus, and decision-making in addition to emotional health. Avoidance behaviors and a decrease in academic involvement are common among students who suffer from digital learning anxiety (Maqsood et al., 2021).

Burnout and Exhaustion

Academic burnout, which is typified by fatigue, disengagement, and waning academic interest, is exacerbated by extended use of digital platforms. Students find it challenging to maintain constant academic efforts due to increased weariness caused by prolonged screen usage, frequent multitasking, and the lack of organized timetables (Wang et

al., 2021; Sultana et al., 2021). Because the lines between academic, personal, and recreational domains are blurred in digital learning environments, burnout frequently appears earlier than in traditional learning environments.

Procrastination and Avoidance Behaviors

Procrastination and academic stress are closely related in digital learning. Academic obligations are frequently neglected by students who are overburdened by constant work, electronic diversions, and evaluation pressure(Agung et al., 2020). Due to the accumulation of unfinished work and approaching deadlines, this procrastination cycle exacerbates stress and lowers academic performance (Hossain et al., 2022).

Reduced Self-Efficacy and Motivation

It has been discovered that high levels of digital academic stress lower students' self-efficacy, or their confidence in their capacity to complete academic assignments successfully (Hasan et al., 2020; Mahapatra et al., 2021). Lower engagement, less involvement in class, and a reluctance to take on difficult activities are frequently the results of a drop in self-confidence. Furthermore, digital stresses including loneliness, a lack of feedback, and assessment anxiety frequently erode intrinsic motivation, which is the inner urge to study for personal progress and fulfilment (Chaturvedi et al., 2021).

Cognitive and Behavioural Disruptions

Additionally contributing to cognitive overload, stress in digital learning settings affects memory, focus, and problem-solving skills (Wang et al., 2022). Learning efficacy is further diminished by common behavioural disturbances such excessive multitasking, frequent social media monitoring, and disengagement during online lectures (Adedoyin et al., 2020). When these maladaptive habits persist, they lead to worse academic results and decreased long-term memory recall. These are all the Behavioural Impact which are also define in the table-3

The behavioural and psychological effects of digital academic stress are interrelated rather than distinct, creating a vicious cycle that gradually deteriorates learning results. Workload demands, unclear exam formats, and erratic internet connectivity can all serve as entrance points for anxiety and mental discomfort (Hasan & Bao, 2020; Sahu, 2020). Students who experience ongoing worry are less able to focus and make decisions, which makes them resort to avoidance strategies like procrastination (Agung et al., 2020; Maqsood et al., 2021). In digital learning settings, the lines between study and relaxation are blurred, which accelerates students' burnout and tiredness as academic duties mount (Wang et al., 2021; Sultana et al., 2021). As a result, students become less confidence in their academic ability and experience a decline in intrinsic motivation and self-efficacy (Mahapatra et al., 2021; Chaturvedi et al., 2021). While excessive multitasking and continuous alerts lead to cognitive overload, which impairs memory and critical thinking, this lack of confidence exacerbates avoidance and disengagement (Wang et al., 2022; Adedoyin et al., 2020). In the end, these stresses work together to create a vicious cycle in which procrastination causes burnout, worry causes procrastination, burnout lowers motivation, and cognitive overload hinders recovery, all of which contribute to poor academic performance and emotional instability.

Academic Stress and Learning Outcomes

In the digital age, students' learning results are significantly impacted by academic stress. Prolonged or extreme stress is substantially associated with detrimental behavioral, psychological, and academic outcomes, even though moderate amounts of stress might occasionally serve as a motivator. Thus, there is a complicated link between academic stress and learning outcomes that is mediated by personal traits, coping mechanisms, and institutional support networks. Reduced academic performance, worse grades, and lower retention rates are all regularly linked to high levels of academic stress (Pascoe et al., 2020). Stress impairs fundamental cognitive abilities that are necessary for academic performance, including working memory, attention span, problem-solving, and critical thinking (Hasan et al., 2020). These deficiencies are made worse in digital learning environments by technological difficulties, anxiety related to online assessments, and continual multitasking, which results in decreased productivity and disengagement (Wang et al., 2022). Additionally, high-stress students are more likely to delay, stop participating in class assignments, and exhibit waning enthusiasm, all of which exacerbate their subpar performance (Agung et al.,

2020). Burnout can also result from prolonged exposure to digital academic stress, which can lower academic perseverance and raise dropout intentions (Sultana et al., 2021).

Mediating Factors

While academic stress has generally negative effects on learning outcomes, several mediating factors can moderate its impact and help students cope more effectively.

Self-Regulated Learning (SRL):

Stress has less of an adverse influence on students who possess good self-regulation abilities, such as efficient time management, goal-setting, and metacognitive awareness (Zimmerman et al., 2021). SRL helps students manage their workloads, control distractions, and adjust to online exams in digital learning, where independence and autonomy are necessary. This lessens the negative impacts of academic stress (Hossain et al., 2022).

Emotional Intelligence (EI):

Because they are able to identify, control, and make positive use of their emotions, emotionally intelligent pupils are better able to handle the demands of the classroom (MacCann et al., 2020). Emotional intelligence (EI) helps students deal with ambiguity, control their annoyance from technical obstacles, and stay focused on difficult assignments. Even in high-stress digital learning contexts, studies have shown that students with higher EI are more resilient, motivated, and accomplish better academically (Aslan et al., 2022).

Social and Institutional Support:

Peer cooperation, teacher-student connection, and institutional support networks all considerably lessen the negative effects of stress. Frequent feedback, group learning chances, and mentorship all help people feel less alone and more like they belong, which lowers stress levels (Chaturvedi et al., 2021). It has been demonstrated that by addressing stress-related issues, institutional techniques such flexible deadlines, digital literacy instruction, and mental health counselling enhance academic performance (Mishra et al., 2023).

Moderate stress

Moderate stress, also known as eustress, can motivate pupils, while excessive and persistent stress is detrimental. Eustress inspires students to achieve academic deadlines and perform well under duress by promoting alertness and improving attention (Salmela-Aro et al., 2021). Short-term stress brought on by impending tests or project deadlines might encourage creativity and problem-solving in digital learning settings. However, stress turns from eustress to distress when it persists, is unmanaged, or is out of proportion to coping mechanisms, which results in disengagement, academic burnout, and a worsening in mental health (Wang et al., 2022). In order to maximize stress's motivational power without letting it become too much to handle, educators and institutions must balance stress levels.Moderate stress and their impact are shown in the table – 4

In digital learning, managing academic stress necessitates a multidimensional strategy that incorporates institutional, emotional, and personal coping mechanisms. Higher self-regulation abilities help students better manage their time, set realistic objectives, and adjust to the demands of online learning, all of which lessen the harmful impacts of stress (Zimmerman et al., 2021; Hossain et al., 2022). This makes self-regulated learning (SRL) essential. By helping students control their irritation, deal with uncertainty, and sustain intrinsic motivation, emotional intelligence (EI) builds resilience at the emotional level. This directly improves academic performance in high-stress digital environments (MacCann et al., 2020; Aslan et al., 2022). Social and institutional support are equally crucial, since peer cooperation, instructor direction, and institutional programs (such counselling and flexible regulations) combat feelings of loneliness and academic strain while enhancing perseverance and general wellbeing. (Chaturvedi et al., 2021; Mishra et al., 2023).It's interesting to note that not all stress is bad; eustress, or mild stress, may be a motivating factor that improves performance under pressure and focus and creativity. But if left unchecked, this stress turns into discomfort, which causes disengagement and burnout (Salmela-Aro et al., 2021; Wang et al., 2022). Thus, to maximize

student achievements in digital learning, a balanced interaction of SRL, EI, support networks, and calibrated stress levels is necessary.

Learning Outcomes in a Digital World

The quality of education, the infrastructure of technology, and the students' capacity to handle academic stress all influence the cognitive, emotional, and behavioral aspects of learning outcomes in digital settings. Higher-order thinking, teamwork, and flexible learning can all be improved by digital education, but these advantages are undermined by excessive stress, which interferes with focus, motivation, and engagement.

Cognitive Outcomes

Effective instructional design and the use of interactive technologies may greatly improve critical thinking, problem-solving, and information retention in digital learning (Dhawan, 2020). Online platforms enable possibilities for collaborative knowledge production, access to a variety of resources, and tailored learning experiences—all of which improve cognitive abilities (Bao, 2020). High levels of academic stress, however, have a detrimental impact on these results. Stress disturbs executive skills including reasoning and analytical thinking, shortens attention spans, and damages working memory (Pascoe et al., 2020; Wang et al., 2022). Further impairing focus and resulting in shallow learning and poor retention are digital distractions and cognitive stress brought on by multitasking, which involves alternating between social media, assignments, and online lectures (Sultana et al., 2021). So, even if digital platforms have cognitive potential, their usefulness is greatly moderated by academic stress.

Affective Outcomes

A key factor in influencing the effectiveness of digital learning is the attitudes, motivation, and emotional health of the students. Persistence in online settings is increased by positive emotional engagement, which includes self-confidence, academic curiosity, and intrinsic motivation (MacCann et al., 2020). On the other hand, high academic stress raises dropout intentions, decreases motivation, and cultivates unfavorable attitudes toward digital learning (Mahapatra et al., 2021). Emotional resilience can be diminished and loneliness exacerbated by a lack of in-person peer connection and teacher assistance (Chaturvedi et al., 2021). Anxiety and burnout brought on by stress further erode zeal, resulting in disengagement and worse academic satisfaction (Hossain et al., 2022). In this situation, the affective dimension is frequently the most susceptible to digital stresses, which has a direct impact on students' decision to continue or stop participating in online learning activities.

Behavioral Outcomes

Study habits, involvement, and engagement all show behavioural learning outcomes in digital education. Positive behavioral results are shown by regular attendance in virtual classrooms, active involvement in online conversations, and teamwork in group projects (Adedoyin et al., 2020). But these habits are significantly impacted by digital stresses such screen weariness, task pressure, and evaluation anxiety. Due to exhaustion and demotivation, stressed students are more likely to delay, avoid online involvement, or turn in assignments late (Agung et al., 2020). Additionally, students' capacity to maintain rigorous academic routines is diminished by digital temptations like social media, multitasking, and gaming, which disrupt regular study habits (Mishra et al., 2023). Students who have robust coping mechanisms and institutional support, on the other hand, exhibit superior behavioral adaptability, resilience, and active engagement in spite of stress.

Strategies to Reduce Academic Stress

Adopting comprehensive measures that integrate institutions, educational innovations, and student-level coping mechanisms is crucial given the widespread nature of academic stress in digital learning. A multifaceted strategy that improves emotional resilience, social connectivity, and digital literacy in addition to addressing academic overload is necessary for effective stress reduction.

Institutional Interventions

Institutional interventions are official measures or programs introduced by an institution to address problems and create a supportive, effective, and healthy environment. These are-

Adaptable Assessment Techniques: Due to worries about fairness, technological difficulties, and ongoing monitoring, online tests can cause more stress. By using flexible assessment techniques like open-book examinations, project-based evaluations, and formative assessments—which place an emphasis on comprehension rather than rote memorization—institutions can lessen the stress associated with tests (Besser et al., 2020).

Digital Literacy and Capacity Building: Due to their lack of experience with online resources, many students find it difficult to use digital platforms. Students and instructors who participate in training programs that improve their digital literacy experience less stress from technology, become more adaptable, and feel more confident in digital settings (Dhawan, 2020).

Mental Health Support Services: Students are more resilient to academic stress when they have access to counselling, stress management classes, and mental health services. Psychological effects can be greatly enhanced by campus-wide programs that address anxiety and exhaustion as well as regular well-being check-ins(Pascoe et al., 2020; Mishra et al., 2023).

Policy-Level Interventions: On a larger scale, policies that assist impoverished students' financial aid, dependable internet, and fair access to digital devices aid in lowering systemic causes of academic stress (Adedoyin et al., 2020).

Pedagogical Approaches

The ideas, techniques, and learning strategies that educators use to help students grow their knowledge, abilities, and values are referred to as pedagogical approaches (Eggen et al., 2019). They stand for the ideas and methods that are applied in classrooms to increase student engagement, foster comprehension, and enhance learning results. In a simple word pedagogical methods are the various ways in which pupils learn and teachers instruct.

Blended Learning: Creating learning environments that strike a balance between academic rigor and student well-being is the equal responsibility of instructional designers and teachers. Blended learning models have been shown to maintain peer engagement and teacher-student connection while reducing digital fatigue through a mix of in-person and online instruction. Stress levels are reduced by blended learning, which offers structure, social interaction, and academic flexibility (Agung et al., 2020).

Interactive Educational Exercises: According to Adedoyin et al. (2020), pedagogical strategies that incorporate group projects, breakout rooms, gamified assignments, and collaborative projects lessen boredom and promote peer support, which decreases feelings of loneliness and increases engagement.

Open Communication: Stress and uncertainty are increased by ambiguous evaluation guidelines and unclear academic expectations. By clearly outlining due dates, objectives, and grading criteria, teachers may help students prepare ahead and lessen their academic anxiety (Hasan et al., 2020).

Adaptive Learning Design: By utilizing AI-powered platforms and customized learning trajectories, students may grow at their own speed, relieving strain on less proficient students while simultaneously posing challenges to more experienced ones (Zhao, 2022).

Student Coping Mechanisms

Student coping mechanisms are the strategies, behaviours, and psychological methods that students use to manage, reduce, or adapt to stress, academic pressure, emotional challenges, and difficult situations in their academic and personal life (Folkman et al., 1985). Students can develop resistance against academic stress on an individual basis by implementing personal solutions.

Time management and self-regulated learning: Students who employ meta cognitive techniques, goal-setting, and prioritizing are better equipped to handle the demands of their task. Because they manage their time between schoolwork and recreation, self-regulated learners often endure less stress (Agung et al., 2020; Hossain et al., 2022).

Yoga and Mindfulness Practices: Research indicates that breathing techniques, yoga, and mindfulness meditation can boost attention and academic performance by lowering digital anxiety, enhancing concentration, and improving emotional regulation(Pascoe et al., 2020; Salmela-Aro et al., 2021).

Peer Support Networks: Peer support groups and collaborative learning assist students in sharing resources, managing their workload, and receiving emotional support. These networks increase desire to stick with online courses, create a feeling of community, and lessen stress associated with isolation (Salmela-Aro et al., 2021).

Healthy Digital Habits: When learning online, students are urged to follow best practices including taking screen breaks, avoiding multitasking, and keeping their postures ergonomic. These methods enhance sustained academic interest and lessen screen fatigue (Wang et al., 2021).

The findings from the reviewed studies reveal a complex picture of how the COVID-19 pandemic reshaped education, mental health, and student well-being. Research consistently highlights that the rapid shift to online learning created both opportunities and challenges. On one hand, digital platforms ensured continuity of education, allowing universities and schools to adapt quickly and avoid prolonged academic disruption (Dhawan, 2020; Bao, 2020). On the other hand, students reported significant levels of academic stress, anxiety, and burnout, often linked to extended screen exposure, lack of in-person interaction, and uncertainties about examinations and career outcomes (Pascoe et al., 2020; Son et al., 2020).Multiple studies confirm that mental health issues intensified during the pandemic, with symptoms of depression, loneliness, and psychological distress being widely reported (Chaturvedi et al., 2021; Hasan & Bao, 2020). Survey-based and interview-driven research also showed that fear of academic year loss, digital fatigue, and technostress further aggravated students' difficulties in adapting to the online mode (Zhao et al., 2022; Mishra et al., 2023). Despite these challenges, some positive aspects emerged: students developed new forms of self-regulated learning (SRL)**,** greater digital literacy, and increased adaptability, supported by innovative learning models such as OCIPSE and institutional interventions (Kirana, 2020; Kitsantas et al., 2025). The results suggest that the pandemic acted as both **a** barrier and a catalyst**.** While it created unprecedented stress and widened educational inequalities, it also accelerated educational innovation, emotional intelligence awareness, and digital transformation**,** which are likely to influence the future of education long after the pandemic.The findings of this review indicate that the pandemic accelerated the digitalization of education but also magnified pre-existing inequalities and stress factors. Although online education acted as a temporary substitute for in-person learning, it came with unintended consequences for students' psychological well-being.

A major concern was the digital divide, which not only hindered access but also created unequal opportunities for learning (Adedoyin et al., 2023). This suggests that future policies must prioritize equitable access to devices and internet connectivity. The reviewed studies also establish a strong link between academic stress and mental health **issues,** such as depression, anxiety, and burnout (Pascoe et al., 2020; Mahapatra et al., 2021). This connection underlines the urgent need for stress management programs**and**mental health services within academic institutions. Another critical insight is the role of emotional intelligence and self-regulated learning. Students with higher EI and SRL skills were more capable of adapting to the challenges of online education (MacCann et al., 2020; Salmela-Aro et al., 2021). Thus, integrating emotional and social skills training into curricula could enhance resilience against

academic stress. Moreover, studies that reported institutional support (e.g., flexible curricula, counseling services, peer collaboration) consistently showed lower stress levels among students (Maqsood et al., 2021; Besser et al., 2022). This highlights the moderating role of teacher competency and institutional strategies in mitigating the negative effects of digital learning. Finally, the emergence of innovative learning models such as OCIPSE and SRL-based frameworks indicates a paradigm shift in pedagogy. These models emphasize student-centered, flexible, and technology-driven approaches to make learning more effective and sustainable (Kirana, 2020; Kitsantas et al., 2025).

CONCLUSION

While digitizing education has revolutionized access, flexibility, and creativity, it has also presented learners with new behavioral, cognitive, and psychological problems. In addition to speeding up the adoption of technology, the move to online and blended learning during and after the COVID-19 pandemic also increased academic stress because of problems like technological barriers, an increased workload, isolation, and pressures related to assessments (Dhawan, 2020; Agung et al., 2020). If left untreated, academic stress impairs cognitive functions such as focus, memory recall, and higher-order thinking abilities, which results in subpar academic performance and disinterest in learning (Pascoe et al., 2020).Simultaneously, the digital environment intensifies the behavioral and emotional effects of stress, including anxiety, procrastination, and decreased intrinsic motivation. These factors can impede the development of lifelong learning abilities and raise dropout rates (Hasan & Bao, 2020; Wang et al., 2021). Accordingly, there is a mostly unfavorable correlation between academic stress and learning outcomes, even if mild stress might serve as eustress, promoting resilience, motivation, and timely academic task completion (Salmela-Aro et al., 2021).Crucially, students can be protected from the negative impacts of academic stress by a number of mediating and protective variables. Effective time management, goal-setting, and metacognitive techniques are examples of self-regulated learning approaches that enable students to adjust to the demands of digital settings (Zimmerman, 2020). By enabling students to control their negative emotions, stay motivated, and retain good attitudes about learning, emotional intelligence improves coping (MacCann et al., 2020). Strong institutional support networks, including chances for peer cooperation, teacher-student engagement, and counselling services, can also be crucial in lowering stress and promoting academic resilience (Adedoyin &Soykan, 2020; Pascoe et al., 2020).Educational institutions must adopt comprehensive interventions for long-term sustainability, such as blended learning models to lessen digital fatigue, flexible pedagogical approaches, training for teachers and students in digital literacy, and mental health resources that promote general well-being. In addition to lowering academic stress, these methods, when consistently used, support the best possible cognitive, emotional, and behavioral learning outcomes in the digital age (Dhawan, 2020; Besser et al., 2020).In summary, there are two realities associated with the digital age: it creates more chances for inclusive and creative education, but it also calls for conscious measures to reduce academic stress. Policymakers, educators, and institutions may establish balanced, supportive ecosystems that optimize the positive impacts of digital learning while reducing its negative consequences on students by placing a higher priority on student well-being than academic accomplishment (MacCann et al., 2020; Salmela-Aro et al., 2021)

Table – 1 Sources of Academic Stress

Sources of Academic Stress	Key Issues	Impact on Students
Technological Barriers	Students face unreliable platforms, poor internet, and limited access to devices; lack of digital literacy adds difficulty.	Causes frustration, cognitive overload, anxiety, disengagement, and academic performance decline.
Workload & Time Management	Students handle multiple tasks, online discussions, and deadlines without direct supervision; blurred personal-academic boundaries	Leads to procrastination, last-minute stress, reduced quality of work, and poor performance.
Screen Fatigue	Prolonged screen exposure for lectures, assignments, and meetings causes physical strain and reduced attention.	Results in headaches, eye strain, musculoskeletal pain, short attention spans, and lower cognitive efficiency.
Isolation & Lack of Peer Support	Lack of face-to-face interactions and informal peer support in online learning environments.	Generates loneliness, alienation, low motivation, and reduced resilience.
Assessment Pressure	Online exams create uncertainty due to technical issues, fairness, monitoring, and fear of dishonesty.	Increases anxiety, insecurity, and distrust in evaluation systems.

Table – 2 Psychological Impacts of Digital Academic Stress

Psychological Impacts	Key Issues	Impact on Students
Anxiety and Uncertainty	Caused by frequent technological glitches, unstable internet, and unclear online assessment protocols.	Creates constant worry about deadlines, missed opportunities, and exam integrity → lowers engagement and learning outcomes
Burnout and Fatigue	Continuous academic demands+blurred boundaries between study and rest → prolonged exposure to digital tools.	Leads to exhaustion, demotivation, reduced participation, and eventual disengagement.

Depression and Social Isolation	Lack of in-person peer interaction and long-term seclusion in online learning	Triggers loneliness, depressive symptoms, and weakens academic perseverance and emotional resilience
Reduced Motivation & Self-Efficacy	Online distractions,multitasking, and assessment anxiety lower confidence in academic abilities.	Causes procrastination, avoidance, and decline in self-belief → reduced performance.
Cognitive Overload	Excessive digital information, multitasking, and constant notifications overwhelm mental capacity.	Weakens focus, memory, and critical thinking → lowers test performance and long-term retention.

Table – 3 Behavioural Impact

Behavioural Impact	Key Issues	Impact on Students
Anxiety and Emotional Distress	Anxiety increases due to unstable internet, unclear exam protocols, and heavy workloads.	Leads to impaired focus, poor decision-making, avoidance, and reduced academic engagement.
Burnout and Exhaustion	Prolonged digital platform use, multitasking, and blurred academic-personal boundaries accelerate fatigue.	Causes disengagement, loss of interest, and earlier onset of burnout compared to traditional learning.
Procrastination and Avoidance Behaviors	Overload of tasks, distractions, and assessment pressure trigger procrastination cycles.	Results in missed deadlines, accumulation of tasks, higher stress, and declining performance.
Reduced Self-Efficacy and Motivation	Stress lowers students' confidence in handling academic challenges; lack of feedback and loneliness erode motivation.	Decreases engagement, participation, and willingness to attempt challenging work.
Cognitive and Behavioural Disruptions	Stress and multitasking create cognitive overload; frequent social media use reduces attention.	Weakens memory, problem-solving, and long-term retention; increases disengagement.

Table – 4 Moderate stress

Moderate stress	Key Issues	Impact
Self-Regulated Learning (SRL)	Involves time management, goal-setting, metacognitive awareness, and self-monitoring.	Reduces academic stress by enabling students to manage workload, distractions, and autonomy in online settings.
Emotional Intelligence	Ability to perceive, regulate, and use emotions effectively in learning.	Helps students overcome frustration from technical issues, deal with uncertainty, and remain resilient. Leads to better motivation and achievement.
Social and Institutional Support	Includes peer collaboration, teacher feedback, group learning, and institutional initiatives.	Enhances belongingness, reduces isolation, and lowers stress. Flexible deadlines, digital literacy training, and counselling improve academic outcomes.
Moderate Stress (Eustress)	Positive stress that boosts motivation, focus, and problem-solving.	Encourages creativity, deadline completion, and alertness. Becomes harmful when unmanaged, turning into distress.

ABSTRACT

This study investigates the application of a hybrid ensemble framework in analyzing sentiment within educational data, specifically targeting student feedback. With growing interest in data-driven insights to improve educational quality, sentiment analysis of student feedback offers valuable perspectives that can inform instructional strategies, enhance the student learning experience, and ultimately improve academic outcomes. By applying a hybrid ensemble approach that combines multiple machine learning algorithms, this study aims to achieve a nuanced understanding of student sentiments, identifying patterns and trends within feedback data to provide educators and institutions with actionable insights. Traditional sentiment analysis models in educational contexts often rely on single-model approaches, which can lack the adaptability and depth needed to capture the complex and varied nature of student sentiment. Hybrid ensemble models, on the other hand, combine techniques such as bagging and boosting, which reduce biases and variances inherent to single models, offering a more robust and reliable sentiment classification. By integrating multiple algorithms, this hybrid ensemble framework is able to provide a more comprehensive and accurate sentiment analysis that can adapt to the unique language, tone, and emotional expressions often found in student feedback. The framework is evaluated on a substantial dataset of student feedback, covering various aspects of the educational experience, including course content, teaching effectiveness, engagement, and support services. The analysis focuses on key performance metrics—such as accuracy, precision, recall, and F1-score—demonstrating the model's efficiency and accuracy in categorizing sentiments into positive, negative, and neutral categories. Additionally, the framework incorporates domain-specific customization, particularly tailored to the language and context of education, which further enhances its ability to capture subtle nuances in student feedback. For instance, terms such as “challenging,” “supportive,” “confusing,” and “inspiring”

carry distinct connotations in the educational domain that general sentiment models might misinterpret. By integrating these domain-specific features, the hybrid ensemble framework demonstrates improved contextual understanding, providing more accurate insights into student sentiments. The findings of this study underscore the potential of using a hybrid ensemble framework to enhance educational quality by informing more targeted and effective instructional strategies. By understanding student sentiment at a granular level, educators and administrators can respond proactively to areas needing improvement, whether they involve clarifying instructional material, improving engagement techniques, or addressing student support concerns. Such insights not only help educators adapt their teaching approaches to better meet student needs but also contribute to a more supportive and conducive learning environment. Furthermore, the framework's scalability allows for its application across various educational settings, from primary education to higher education institutions, making it a versatile tool for educational research and institutional feedback analysis. The study concludes that domain-specific sentiment analysis, supported by hybrid ensemble techniques, provides a powerful approach for continuous improvement in education. This research paves the way for future developments in educational sentiment analysis, advocating for the adoption of advanced machine learning frameworks that account for the specific linguistic and contextual elements of educational data. Ultimately, the implementation of such tailored sentiment analysis models can play a critical role in fostering a responsive and student-centered educational system that enhances learning outcomes and satisfaction.

Keywords: Hybrid Ensemble Framework, Sentiment Analysis in Education, Student Feedback Analysis, Instructional Improvement, Educational Environment Optimization

INTRODUCTION

In contemporary education, understanding the perspectives of students is crucial for improving the quality of teaching and learning outcomes. Student feedback, gathered through surveys, course evaluations, and other mechanisms, provides valuable insights into how educational practices are perceived and experienced by learners. Traditionally, feedback has been analyzed through manual methods, such as qualitative analysis or simple quantitative scoring. However, as educational systems become increasingly complex and diverse, there is a growing need for advanced tools and methodologies that can capture the depth and nuance of student sentiments. Sentiment analysis, a field of study that focuses on detecting and interpreting emotional tone in textual data, has emerged as a promising solution to this challenge.

The Importance of Understanding Student Feedback

Student feedback plays a pivotal role in shaping educational practices. It enables educators to evaluate their teaching strategies, improve course content, and make adjustments to the learning environment. Moreover, feedback provides insights into the effectiveness of instructional methods, student engagement, and the overall learning experience. As a result, educational institutions increasingly rely on student feedback to inform decisions about curriculum design, teaching methods, and resource allocation (Fryer, 2019). Understanding student feedback is not only about gathering data; it is about interpreting that data to make meaningful improvements. However, manually analyzing open-ended feedback can be time-consuming and prone to subjectivity. Sentiment analysis provides a way to automate this process, allowing institutions to efficiently analyze large volumes of student feedback and identify patterns, sentiments, and trends that might otherwise go unnoticed. By doing so, sentiment analysis offers the potential to create a more responsive and data-driven educational system that is better equipped to meet the evolving needs of students.

Challenges in Traditional Sentiment Analysis

Traditional methods of sentiment analysis often struggle when applied to the context of educational data. The language used in student feedback is highly diverse, reflecting the varied backgrounds, experiences, and perspectives of the students. This diversity presents several challenges for conventional sentiment analysis methods. For example, educational data often contains domain-specific jargon, which may not be recognized by general-

purpose sentiment analysis models (Balahur, 2013). Additionally, the formality of student feedback can vary significantly. Some students may use highly formal language, while others may express themselves informally, using slang or colloquial terms. These variations can make it difficult to accurately classify sentiments using a one-size-fits-all approach. Another challenge is the contextual nature of sentiment in education. A single word or phrase may have different meanings depending on the context in which it is used. For instance, the word "difficult" can have a negative sentiment in one context (e.g., "The exam was difficult"), but a positive sentiment in another (e.g., "The challenging assignments were beneficial"). This complexity requires more advanced models that can account for nuances in meaning and sentiment. Moreover, traditional sentiment analysis methods, such as lexicon-based approaches, often rely on predefined lists of positive and negative words. While effective in some contexts, these approaches may fail to capture the full range of sentiments expressed in student feedback, leading to incomplete or inaccurate results (Pang & Lee, 2008).

Advancements in Sentiment Analysis for Education

To address the limitations of traditional sentiment analysis approaches, recent research has focused on developing more sophisticated methods that are better suited to the educational domain. One such approach is the use of hybrid ensemble frameworks, which combine multiple machine learning algorithms to improve the accuracy and robustness of sentiment classification. Ensemble learning techniques have been shown to outperform single-model approaches in a variety of domains, including sentiment analysis, by leveraging the strengths of multiple models (Zhou, 2012).

The hybrid ensemble framework, which is the focus of this study, is designed to overcome the challenges of traditional sentiment analysis methods by integrating several machine learning algorithms. These algorithms are optimized to work together to capture the complex and nuanced sentiments expressed in student feedback. By combining models such as Random Forest, Gradient Boosting, and Support Vector Machine (SVM), the ensemble framework can better handle the diversity of language used in educational data and improve the accuracy of sentiment classification (Dietterich, 2000). Furthermore, the hybrid ensemble framework is specifically tailored to the educational context. It incorporates domain-specific features, such as educational keywords and context-dependent sentiment scoring, to enhance the model's ability to understand the unique characteristics of student feedback. This approach allows for a more accurate and meaningful analysis of student sentiments, providing educators with actionable insights that can inform their teaching strategies and improve the learning experience.

Motivation for the Study

The motivation behind this study is to develop a more effective and context-sensitive approach to sentiment analysis in education. Traditional sentiment analysis methods are often inadequate for analyzing the complex and diverse nature of student feedback. By applying a hybrid ensemble framework, this research aims to provide a more accurate and insightful analysis of student sentiments, allowing educators to make data-driven decisions that improve teaching practices and student engagement. The study also seeks to contribute to the growing body of literature on sentiment analysis in education. While sentiment analysis has been widely applied to various domains, its application to the education sector remains relatively underexplored. This research aims to fill this gap by demonstrating how a hybrid ensemble framework can be used to analyze student feedback across multiple courses and disciplines, highlighting the potential for sentiment analysis to enhance educational practices. The findings of this study are expected to provide valuable insights into how sentiment analysis can be leveraged to inform instructional strategies, improve student engagement, and create more responsive learning environments.

Research Objectives

The primary objective of this research is to assess the effectiveness of a hybrid ensemble framework in analyzing student feedback. Specifically, the study aims to:

- **Tailor the Hybrid Ensemble Framework**: Adapt the previously developed hybrid ensemble framework for sentiment analysis in the educational context, incorporating domain-specific features and optimization techniques.

- **Evaluate Model Performance**: Evaluate the performance of the hybrid ensemble framework in comparison to traditional sentiment analysis approaches, such as lexicon-based methods, across multiple courses and disciplines.
- **Provide Actionable Insights**: Use the results of the sentiment analysis to provide actionable insights into student perceptions, learning experiences, and areas for improvement in teaching methods.
- **Enhance Teaching Strategies**: Demonstrate how sentiment analysis can be used to inform instructional strategies, improve student engagement, and create a more supportive and effective learning environment.

The increasing complexity of educational systems and the growing reliance on student feedback to inform teaching practices make it essential to adopt more sophisticated tools for sentiment analysis. This paper proposes a hybrid ensemble framework as a solution to the challenges faced by traditional sentiment analysis approaches in the educational context. By leveraging multiple machine learning models and incorporating domain-specific features, the hybrid ensemble framework promises to offer a more accurate and nuanced analysis of student feedback, enabling educators to make data-driven decisions that improve teaching strategies and student engagement. The findings of this study are expected to contribute to the growing body of research on sentiment analysis in education and provide a foundation for future developments in this field.

Structure of the Paper

The structure of this paper is as follows: In Section 2, a review of the related literature on sentiment analysis in education is provided, highlighting the challenges and advancements in the field. Section 3 outlines the methodology used in this study, including the data collection process, preprocessing techniques, feature extraction methods, and the hybrid ensemble framework. Section 4 presents a case study evaluating the performance of the hybrid ensemble model, comparing its results with traditional sentiment analysis methods. Section 5 discusses the implications of the findings for educational practice, highlighting the benefits and challenges of applying sentiment analysis in education. Finally, Section 6 concludes the paper and outlines directions for future research.

Related Work

Sentiment analysis is an interdisciplinary research field that leverages techniques from natural language processing (NLP), machine learning (ML), and computational linguistics to determine the sentiment or emotional tone expressed in a piece of text. In the context of education, sentiment analysis plays a critical role in analyzing student feedback, which can provide valuable insights into the quality of teaching, curriculum, and student engagement. Over the years, a number of studies have explored the application of sentiment analysis to educational data, particularly student feedback, in order to understand the underlying sentiments and identify areas for improvement. This section provides a review of the existing literature on sentiment analysis in education, focusing on traditional approaches, the challenges faced, and recent advancements, particularly those involving machine learning techniques.

Traditional Approaches to Sentiment Analysis in Education

In the early stages of sentiment analysis, researchers mainly relied on lexicon-based approaches. These approaches use predefined lists of positive and negative words (sentiment lexicons) to classify the sentiment of a given text. The sentiment score is typically calculated by aggregating the individual sentiment scores of words in the text. These methods are relatively simple to implement and can be effective when the text is straightforward and the vocabulary used is consistent. However, in the context of student feedback, this approach has its limitations. For instance, in educational contexts, students may use informal language, domain-specific terms, or phrases that convey sentiment in a way that is not captured by standard sentiment lexicons. Words that are neutral in one context may carry sentiment in another. For example, the term "challenging" might indicate a positive sentiment when referring to a difficult but rewarding task but might convey negative sentiment when referring to an overly difficult exam. To address these limitations, researchers have developed a variety of techniques to enhance the effectiveness of sentiment analysis in educational contexts. One of the earliest studies in applying sentiment analysis to education involved analyzing student evaluations of instructors. For example, the work of Mc Naught and Lam (2010) explored how sentiment analysis could be used to assess the overall satisfaction of students in relation to course content and

teaching. They employed a lexicon-based approach combined with manual annotation to categorize the feedback into positive, negative, or neutral sentiments. While this approach provided valuable insights, it was clear that more advanced methods were needed to handle the complexity and diversity of student feedback.

Challenges in Applying Sentiment Analysis to Educational Data

Despite its usefulness, traditional sentiment analysis methods face significant challenges when applied to educational data. The complexity of the language used in student feedback can make it difficult to accurately classify sentiments using lexicon-based or rule-based methods. Several key challenges in this context include:

Diversity of Language: Students use a variety of linguistic styles and expressions in feedback, including colloquial language, slang, and academic jargon. A standard sentiment lexicon may fail to capture these nuances, resulting in inaccurate sentiment classification. For example, the word "difficult" may have a positive connotation in one context, such as "difficult but rewarding," but may carry a negative sentiment when referring to "difficult and frustrating" tasks.

Context Dependency: Sentiment is often context-dependent, especially in educational settings. A word or phrase may express a different sentiment depending on the specific context in which it is used. For instance, "good" might be used to describe both an easy exam ("Good for beginners") and a well-structured course ("Good teaching methods"). Lexicon-based methods struggle with these subtleties because they do not account for the broader context.

Aspect-Based Sentiment: In educational feedback, students often provide sentiments on different aspects of the course, such as teaching quality, course material, assignments, and overall experience. Traditional sentiment analysis methods may fail to identify these multiple aspects of feedback, resulting in a single, aggregated sentiment score for the entire text. Aspect-based sentiment analysis, on the other hand, aims to identify and classify sentiment specific to different aspects of the course or teaching, making it a more refined approach.

Sarcasm and Irony: Sarcasm and irony are common in human communication and are particularly prevalent in student feedback. A student might sarcastically comment, "This course is absolutely amazing," when, in fact, they are expressing dissatisfaction. Traditional sentiment analysis techniques often struggle to detect sarcasm, leading to incorrect sentiment classification. These challenges highlight the need for more advanced methods of sentiment analysis that can overcome the limitations of lexicon-based approaches. Researchers have turned to machine learning (ML) and deep learning (DL) techniques to address these challenges, as these methods can learn complex patterns in data and adapt to the intricacies of student feedback.

Machine Learning Approaches to Sentiment Analysis in Education

Over the past decade, machine learning approaches have gained prominence in the field of sentiment analysis. Machine learning models can learn from labeled data to recognize patterns in text and classify sentiments with high accuracy. In the context of educational feedback, machine learning models have shown considerable promise in addressing the challenges outlined above. One of the most widely used machine learning algorithms for sentiment analysis is the Support Vector Machine (SVM). SVMs are particularly effective for binary classification tasks, such as classifying feedback into positive or negative sentiments. Research by Koppel et al. (2007) demonstrated the use of SVM for analyzing student feedback, showing that SVM models can outperform lexicon-based approaches in terms of accuracy. However, SVM models require extensive feature engineering, which can be a time-consuming process. Additionally, SVMs often perform poorly when the training data is unbalanced, such as when the number of positive and negative feedback comments is uneven. Another popular machine learning algorithm used in sentiment analysis is Random Forest (RF). RF is an ensemble learning technique that aggregates the predictions of multiple decision trees to improve classification accuracy. Research by Ribeiro et al. (2016) showed that Random Forests can effectively handle the diversity of language found in educational feedback, outperforming traditional methods like SVM in

some cases. RF models tend to be more robust and are less sensitive to noise in the data, making them an attractive choice for analyzing student feedback.

Naive Bayes (NB) is another machine learning algorithm that has been applied to sentiment analysis in education. Although simpler than SVMs and RF, Naive Bayes models have been found to work effectively on smaller datasets or in cases where the features are easily separable. For example, in research by Jain et al. (2015), Naive Bayes classifiers were used to analyze student feedback on online courses, and the results showed that they provided accurate sentiment classification despite the relatively small size of the dataset.

Deep Learning Approaches to Sentiment Analysis in Education

In recent years, deep learning models have become a prominent approach in sentiment analysis, particularly for text classification tasks. Unlike traditional machine learning models, deep learning algorithms do not require feature engineering and can automatically learn relevant features from raw text data. This makes them particularly effective in handling large, complex datasets, such as student feedback, where feature extraction can be a challenging task.

One of the most successful deep learning techniques in sentiment analysis is the Recurrent Neural Network (RNN), particularly the Long Short-Term Memory (LSTM) variant. LSTMs are well-suited for sequential data, such as text, because they can capture long-range dependencies and context in a sequence of words. In research by Yoon et al. (2017), LSTM networks were used to analyze student feedback in the context of online learning platforms, achieving high accuracy in sentiment classification. The ability of LSTMs to model contextual dependencies makes them ideal for analyzing the intricate and nuanced language found in student feedback.

Another powerful deep learning architecture is the Convolutional Neural Network (CNN), which has shown promise in text classification tasks. CNNs, originally designed for image recognition, can also be applied to text data by treating words as "pixels" in a sequence. In a study by Zhang et al. (2015), CNNs were used for sentiment analysis of course evaluations, and the results showed that CNNs can effectively capture local features in text, such as sentiment-bearing phrases or expressions. While CNNs are typically used for feature extraction, they can also be combined with other models, such as LSTMs, to improve overall performance. Recent advances in Transformers, a deep learning architecture that has revolutionized NLP, have also been applied to sentiment analysis in education. The BERT (Bidirectional Encoder Representations from Transformers) model, for example, has been shown to outperform traditional deep learning models in a variety of NLP tasks. BERT can capture context in a more sophisticated manner by using both left-to-right and right-to-left context, making it especially effective for understanding complex sentiments in student feedback (Devlin et al., 2019). Studies by Choi et al. (2021) have applied BERT for sentiment analysis of student feedback, achieving impressive results in terms of classification

Hybrid Ensemble Approaches

Recent research has moved towards combining multiple machine learning and deep learning models into a hybrid ensemble approach in order to improve the accuracy and robustness of sentiment classification. These ensemble models combine the strengths of individual algorithms, such as SVMs, Random Forests, and deep learning models like LSTMs or CNNs, to achieve better performance than any single model. For example, in a study by Li et al. (2020), a hybrid ensemble approach was used for sentiment analysis of student feedback in online education. The authors combined multiple machine learning models, including SVM, Random Forest, and Gradient Boosting, with a deep learning model based on LSTM. The hybrid ensemble framework was found to significantly improve sentiment classification accuracy by combining the complementary strengths of each model. Another promising hybrid approach is the combination of feature extraction methods with machine learning and deep learning algorithms. For example, researchers have experimented with combining word embeddings, such as Word2Vec or GloVe, with deep learning models like LSTMs and Transformers. These embeddings allow the model to better understand the semantic meaning of words, improving its ability to classify sentiments accurately.

Applications in Educational Settings

Sentiment analysis in education has found applications in a variety of areas, including:

- **Course Evaluation and Feedback**: Sentiment analysis has been used to evaluate student feedback on courses, instructors, and academic programs. By analyzing feedback, universities can gain insights into the strengths and weaknesses of their courses and identify areas for improvement. For example, a study by Lee et al. (2018) analyzed student feedback on online courses using sentiment analysis to assess the effectiveness of teaching methods and course materials.
- **Early Warning Systems**: Sentiment analysis has been applied to early warning systems that track student performance and engagement. By analyzing sentiment in forum posts, emails, and other communication channels, educational institutions can identify students at risk of disengagement or failure and intervene early. This approach has been explored in studies by Goh et al. (2019), where sentiment analysis was used to predict student success in online learning environments.
- **Real-time Feedback and Improvement**: Institutions can use sentiment analysis in real-time to adjust teaching methods, course content, and materials based on student sentiment. For instance, if students express dissatisfaction with a particular lesson or module, educators can quickly modify the content to address these concerns. This approach has been explored in real-time systems developed by researchers like Pang et al. (2020).

The application of sentiment analysis to educational data has evolved significantly over the years, with traditional lexicon-based approaches giving way to more sophisticated machine learning and deep learning models. While challenges remain, particularly with respect to sarcasm, context dependency, and aspect-based sentiment, recent advancements in deep learning techniques, such as LSTMs, CNNs, and Transformers, have shown great promise in improving the accuracy and robustness of sentiment analysis in educational contexts. Hybrid approaches that combine multiple models are also gaining traction, providing even greater accuracy and flexibility in handling diverse student feedback. As sentiment analysis continues to play an increasingly important role in educational settings, further research is needed to explore its full potential, particularly in developing systems that can provide real-time, actionable insights to educators and administrators. With the rapid advancement of machine learning technologies, the future of sentiment analysis in education looks promising, offering new opportunities for improving teaching quality, student engagement, and academic performance.

METHODOLOGY

This section presents the methodology for applying a hybrid ensemble framework to analyze student feedback using sentiment analysis. The approach builds on previously established techniques, specifically designed to address the unique challenges posed by educational data. By adapting the hybrid framework for educational data, the methodology emphasizes data collection, preprocessing, feature extraction, and ensemble model optimization. This section details each component in-depth and includes pseudo code for key steps to clarify the implementation process.

Data Collection

The dataset used in this study consists of student feedback collected from multiple university courses. Feedback is gathered through surveys and course evaluations, which contain free-text comments. The data represents a wide range of student opinions about course content, teaching quality, engagement levels, and other aspects of the educational experience. Student feedback typically spans a variety of sentiments, from positive comments on helpfulness and clarity to negative remarks about difficulty and confusion. The dataset includes comments from different academic disciplines, such as STEM (Science, Technology, Engineering, and Mathematics), humanities, and social sciences, making it a rich resource for analyzing sentiment across contexts.

Data Preprocessing

Preprocessing is essential to standardize and clean the collected data, ensuring that it is suitable for analysis. The steps involved in data preprocessing are as follows:

Text Normalization: Text normalization involves converting all text to lowercase and removing any special characters or unnecessary symbols. This step is important to avoid discrepancies arising from inconsistent capitalization and punctuation. For instance, "Good" and "good" should be treated as the same word.

Pseudocode for text normalization

```
function normalize_text(text):
text = text.lower()              # Convert text to lowercase
text = remove_special_characters(text)  # Remove punctuation and special symbols
text = correct_spelling(text)     # Optional step for spelling correction
return text
```

Tokenization: Tokenization is the process of splitting the text into smaller units, such as words or phrases, for easier analysis. For example, "The course was difficult" would be tokenized into ["The", "course", "was", "difficult"]. Tokenization breaks the text down into components that can be analyzed individually.

Pseudocode for tokenization

```
function tokenize(text):
tokens = split_into_words(text)   # Split text into individual words
return tokens
```

Stop-word Removal: Stop words are common words (e.g., "the," "is," "and") that do not contribute meaningful sentiment information. Removing these stop words helps to reduce noise in the data and allows the sentiment analysis model to focus on the relevant content. A stop-word list specific to the educational context can be created to improve the quality of pre processing. The pre processing pipeline also considered common negation terms such as "not", "never", and "no". When such terms appeared before sentiment-bearing words, the corresponding sentiment polarity was reversed to ensure accurate sentiment classification.

Pseudocode for stop-word removal

```
function remove_stopwords(tokens, stopwords):
return [word for word in tokens if word not in stopwords]
```

Feature Extraction

Once the data has been preprocessed, the next step is feature extraction, which is crucial for capturing the nuanced sentiment expressed in student feedback. This section outlines two primary feature extraction methods employed in this study: domain-specific keywords and sentiment scoring.

Domain-Specific Keywords

The use of domain-specific keywords helps identify educational themes in student feedback. In the context of sentiment analysis for educational data, common themes might include "engaging," "difficult," "helpful," "feedback," and "understanding." A lexicon of such keywords is developed based on a review of common student sentiments in course evaluations. Since feedback was collected from STEM, Humanities, and Social Science courses, discipline-specific educational keywords were incorporated during feature extraction. This enabled the framework to capture variations in terminology and sentiment expressions across different academic domains. These keywords are particularly useful for understanding specific areas of sentiment in educational contexts. For example, the presence of the word "engaging" might suggest a positive sentiment towards course content, while "difficult" could indicate negative sentiment related to course difficulty.

Pseudocode for domain-specific keyword extraction:

```
function extract_keywords(text, keyword_list):
tokens = tokenize(text)
```

keywords = [word for word in tokens if word in keyword_list]
return keywords

Sentiment Scoring
